The Standard tMomCommit component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the Connection component used in your Job.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Close Connection</th>
<th>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</th>
</tr>
</thead>
</table>

**Warning:**

If you want to use a Row > Main connection to link tMomCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is more commonly used with other tMom* components, especially with the tMomConnection and tMomRollback components. |

**Related scenario**

For **tMomCommit** related scenario, see *Inserting data in mother/daughter tables* on page 2452.
tMomConnection

Opens a connection to the MQ Server for communication.

**tMomConnection Standard properties**

These properties are used to configure tMomConnection running in the Standard Job framework.

The Standard tMomConnection component belongs to the Internet family.

The component in this framework is available in all [Talend products](http://www.talend.com).

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Failover</strong></td>
<td>Select this check box to use the ActiveMQ failover transport. For more information about the failover transport, see <a href="#">Failover Transport Reference</a>. This check box is available only when <a href="#">ActiveMQ</a> is selected from the <a href="#">MQ server</a> drop-down list and the <a href="#">Static Discovery</a> check box is cleared.</td>
</tr>
<tr>
<td><strong>Static Discovery</strong></td>
<td>Select this check box to use the ActiveMQ static transport discovery mechanism. For more information about the static transport, see <a href="#">Static Transport Reference</a>. This check box is available only when <a href="#">ActiveMQ</a> is selected from the <a href="#">MQ server</a> list and the <a href="#">Failover</a> check box is cleared.</td>
</tr>
<tr>
<td><strong>URI parameters</strong></td>
<td>Enter the URI parameters. This field is available only when the <a href="#">Failover</a> or <a href="#">Static Discovery</a> check box is selected.</td>
</tr>
<tr>
<td><strong>MQ server</strong></td>
<td>Select the type of the MQ server(s) to be connected from the drop-down list, either <a href="#">ActiveMQ</a> or <a href="#">WebSphere MQ</a>.</td>
</tr>
<tr>
<td><strong>Use SSL Transport</strong></td>
<td>Select this check box to use the ActiveMQ SSL transport. For more information about the SSL transport, see <a href="#">SSL Transport Reference</a>. This check box is available only when <a href="#">ActiveMQ</a> is selected from the <a href="#">MQ server</a> list.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>The host name or IP address of the MQ server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>The listening port of the MQ server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication credentials. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Use Transacted</strong></td>
<td>Select this check box to set the session created to be transacted.</td>
</tr>
</tbody>
</table>
This check box is available only when **ActiveMQ** is selected from the **MQ server** drop-down list.

<table>
<thead>
<tr>
<th>Channel</th>
<th>Specify the name of the channel through which the connection is established. The default value is <strong>DC.SVRCONN</strong>. This field is available only when <strong>WebSphere MQ</strong> is selected from the <strong>MQ server</strong> drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>QueueManager</td>
<td>Specify the name of the queue manager to which the connection is established. This field is available only when <strong>WebSphere MQ</strong> is selected from the <strong>MQ server</strong> drop-down list.</td>
</tr>
</tbody>
</table>

**Use or register a shared Connection**

Select this check box to share your connection or use a connection shared by a parent or child Job. This allows you to share one single connection among several connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

**Shared Connection Name**
Enter the shared connection name. This field is available only when the **Use or register a shared Connection** check box is selected.

#### Advanced settings

**Additional options**

Define the additional transport options in the table. This table is available only when the **Failover** or **Static Discovery** check box in the **Basic settings** view is selected.

- **Option name**: the name of the option.
- **Option value**: the value of the option.

For example, enter **maxReconnectAttempts** in the **Option name** field and then **0** in the **Option value** field so that no attempt is made to retry the connection when no server is available.

For more information about the failover transport options, see [Failover Transport Reference](#).

For more information about the static discovery transport options, see [Static Transport Reference](#).

**Set Cipher Suite**

Select this check box to enable the Cipher Suite list from which you can specify the Cipher Suite to be used with WebSphere MQ SSL.

For further information about Cipher Suite, see [CipherSpecs and their equivalent CipherSuites supported by IBM WebSphere MQ](#).

Available when **WebSphere MQ** is selected in the **MQ Server** list.

**Custom Cipher Suite**

Select this check box to allow you to customize Cipher Suite.
**IBM Cipher Mappings**: Use the IBM Java Cipher Suite to IBM MQ Cipher Spec Mappings.

**Oracle Cipher Mappings**: Use the Oracle Cipher Suite to IBM MQ Cipher Spec Mappings.

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

| Usage rule | This component is more commonly used with other tMom* components, especially with the **tMomCommit** and **tMomRollback** components. |

**Limitation**

| Limitation | This component supports ActiveMQ and WebSphere MQ servers. |

**Related scenario**

For a similar scenario, see **tMysqlConnection** on page 2451.
tMomInput

Fetches a message from a queue on a Message-Oriented Middleware (MOM) system and passes it on to the next component.

tMomInput makes it possible to set up asynchronous communications via a MOM server.

For further information about the messaging brokers supported by this component, see Messaging brokers supported by Talend messaging components.

**tMomInput Standard properties**

These properties are used to configure tMomInput running in the Standard Job framework.

The Standard tMomInput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td>Keep Listening</td>
<td>Select this check box to keep the MOM server listening for and fetching new messages. This check box is not visible when ActiveMQ or WebSphere MQ is selected from the MQ server list and the receive number of messages check box is selected.</td>
</tr>
<tr>
<td>Sleeping time (in sec)</td>
<td>Specify the timeout interval (in seconds) within which the next message must be received. This field is available in any one of the following situations: • JBoss Messaging is selected from the MQ server list and the Keep Listening check box is selected. • ActiveMQ is selected from the MQ server list and the Keep Listening check box is cleared. • ActiveMQ is selected from the MQ server list and the receive number of messages and Timeout for receiver check boxes are selected.</td>
</tr>
<tr>
<td>receive number of messages</td>
<td>Select this check box to set the maximum number of messages that can be received. This check box is available when ActiveMQ or WebSphere MQ is selected from the MQ server list and the Keep Listening check box is cleared.</td>
</tr>
<tr>
<td>maximum messages</td>
<td>Enter the maximum number of messages you can receive. This field is available only when the receive number of messages check box is selected.</td>
</tr>
<tr>
<td><strong>Timeout for receiver</strong></td>
<td>Select this check box and specify the timeout interval for the receiver in the <strong>Sleeping time (in sec)</strong> field. This check box is available only when the <strong>receive number of messages</strong> check box is selected.</td>
</tr>
<tr>
<td>--------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><strong>Failover</strong></td>
<td>Select this check box to use the ActiveMQ failover transport. For more information about the failover transport, see <a href="#">Failover Transport Reference</a>. This check box is available only when <strong>ActiveMQ</strong> is selected from the <strong>MQ server</strong> list and the <strong>Static Discovery</strong> check box is cleared.</td>
</tr>
<tr>
<td><strong>Static Discovery</strong></td>
<td>Select this check box to use the ActiveMQ static transport discovery mechanism. For more information about the static transport, see <a href="#">Static Transport Reference</a>. This check box is available only when <strong>ActiveMQ</strong> is selected from the <strong>MQ server</strong> list and the <strong>Failover</strong> check box is cleared.</td>
</tr>
<tr>
<td><strong>URI parameters</strong></td>
<td>Enter the URI parameters. This field is available only when the <strong>Failover</strong> or <strong>Static Discovery</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>MQ server</strong></td>
<td>Select the type of the MQ server(s) to be connected from the list: <strong>ActiveMQ</strong>, <strong>JBoss Messaging</strong>, or <strong>WebSphere MQ</strong>. According to the server type selected, the parameters required differ slightly.</td>
</tr>
<tr>
<td><strong>Use SSL Transport</strong></td>
<td>Select this check box to use the ActiveMQ SSL transport. For more information about the SSL transport, see <a href="#">SSL Transport Reference</a>. This check box is available only when <strong>ActiveMQ</strong> is selected from the <strong>MQ server</strong> list.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Enter the host name or IP address of the MQ server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Enter the listening port of the MQ server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication credentials. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Channel</strong></td>
<td>Specify the name of the channel through which the connection is established. The default value is <strong>DC.SVRCONN</strong>. This field is available only when <strong>WebSphere MQ</strong> is selected from the <strong>MQ server</strong> list.</td>
</tr>
<tr>
<td><strong>Message From</strong></td>
<td>Type in the message source, exactly as expected by the server; this must include the type and name of the source. e.g.: queue/A or topic/testtopic Note that the field is case-sensitive. This field is available only when <strong>ActiveMQ</strong> or <strong>JBoss Messaging</strong> is selected from the <strong>MQ Server</strong> list.</td>
</tr>
</tbody>
</table>
| **Message Type** | Select the message type, either **Topic** or **Queue**.  
This field is available only when **ActiveMQ** or **JBoss Messaging** is selected from the **MQ Server** list. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Message Body Type</strong></td>
<td>Select the message body type: <strong>Text Message</strong>, <strong>Bytes Message</strong> or <strong>Map Message</strong>.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component.  
In the context of **tMomInput** usage, the schema is comprised of two columns: **From** and **Message**, and the column names are read only. |
| **QueueManager** | Specify the name of the queue manager to which the connection is established.  
This field is available only when **WebSphere MQ** is selected from the **MQ server** list. |
| **MessageQueue** | Enter the name of the message queue into which message queueing applications can put messages.  
This field is available only when **WebSphere MQ** is selected from the **MQ server** list. |
| **Is using message id to fetch** | Select this check box to fetch messages according to their IDs.  
This check box is available only when **Text Message** or **Bytes Message** is selected from the **Message Body Type** list. |
| **Commit (delete message after read from the queue)** | Select this check box to force a commit after reading each message from the queue.  
This check box is available only when **WebSphere MQ** is selected from the **MQ server** list and the **Browse message** check box in the **Advanced settings** view is cleared. |
| **Backout messages to input queue** | Select this check box to put the message back into the queue after reading it.  
This check box and the **Browse message** check box in the **Advanced settings** view enable you to read messages non-destructively from the queue. For further information, see [https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqaw07.pdf](https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqaw07.pdf).  
This check box is available only when **WebSphere MQ** is selected from the **MQ server** list and the **Keep Listening**, **Commit (delete message after read from the queue)** and **Browse message** check boxes are cleared. |
| **Backout messages to backout queue (when backoutCount of message reach the threshold value)** | Select this check box to backout the messages to the backout queue defined in the Websphere MQ manager when the backout count reaches the configured threshold which is a property of the queue in the Websphere MQ server.  
This check box is available only when **WebSphere MQ** is selected from the **MQ server** list and the **Keep Listening**, **Commit (delete message after read from the queue)** and **Browse message** check boxes are cleared. |
| tMomInput | 
| --- | --- |
| **Set Transacted** | Select this check box to transact the session. For further information about this parameter, see [https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf](https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf). |
| **Note:** | Selecting this check box will ignore the settings in the **Acknowledgement Mode** list in the **Advanced settings** view of tMomInput. |
|  | This check box is available only when **ActiveMQ** is selected from the **MQ server** list. |
| **start server** | Select this check box to force a start of the ActiveMQ server. |
|  | This check box is available only when **ActiveMQ** is selected from the **MQ server** list. |

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional options</strong></th>
<th>Define the additional transport options in the table. This table is available only if you select the <strong>Failover</strong> or <strong>Static Discovery</strong> check box in the <strong>Basic settings</strong> view.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Option name</strong>: the name of the option.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Option value</strong>: the value of the option.</td>
</tr>
<tr>
<td></td>
<td>For example, enter <code>maxReconnectAttempts</code> in the <strong>Option name</strong> field and then 0 in the <strong>Option value</strong> field so that no attempt is made to retry the connection when no server is available for the failover mode.</td>
</tr>
<tr>
<td></td>
<td>For more information about the failover transport options, see <a href="https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf">Failover Transport Reference</a>.</td>
</tr>
<tr>
<td></td>
<td>For more information about the static discovery transport options, see <a href="https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf">Static Transport Reference</a>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Acknowledgement Mode</strong></th>
<th>Select an acknowledgement mode from the list to indicate that the client will acknowledge any messages it receives:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Auto Acknowledge</strong>: With this acknowledgement mode, the client automatically acknowledges a message when it has either successfully returned from a call to receive, or the message listener it has called to process the message successfully returns.</td>
</tr>
<tr>
<td></td>
<td><strong>Client Acknowledge</strong>: With this acknowledgement mode, the client acknowledges a message by calling a message’s acknowledge method.</td>
</tr>
<tr>
<td></td>
<td><strong>Dups OK Acknowledge</strong>: This acknowledgement mode instructs the session to lazily acknowledge the delivery of messages.</td>
</tr>
</tbody>
</table>
### Note:
If the **Set Transacted** check box of tMomOutput is selected, **Acknowledgement Mode** will be ignored. This check box is enabled when the MQ server is **ActiveMQ** or **JBoss Messaging**.

### Get Jms Header
Select this check box to receive the Jms headers through the mapping from Jms fields onto MQ Series fields. When this check box is checked, you can specify the Jms header and the corresponding reference column name in the line(s) you added by clicking the plus button in the **Parameters** table.

**Note:**
This check box is enabled when the MQ server is **ActiveMQ** or **JBoss Messaging**.

### Get Jms Properties
Select this check box to receive the Jms properties mapped to MQMD fields. When this check box is checked, you can specify the property name, the property type and the reference column name in the line(s) you added by clicking the plus button in the **Parameters** table.

For further information about the usage of Jms properties, see [https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf](https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf).

(Available when **ActiveMQ** or **JBoss Messaging** is selected in the **MQ Server** list.)

### Browse message
Select this check box to disable **Commit (delete message after read from the queue)** check box and **Backout messages to input queue** check box in the **Basic settings** view and open the queue to browse messages.

**Note:**
This check box and the **Backout messages to input queue** check box in the **Basic settings** view enable you to read messages non-destructively from the queue. **Browse message** check box is visible only when the MQ server is WebSphere MQ with the **Backout messages to input queue** check box cleared. For further information, see [http://publib.boulder.ibm.com/infocenter/wmqv7/v7r0m0/index.jsp?topic=%2Fcom.ibm.mq.java.doc%2Fcom%2Fibm%2Fmq%2FMCQ.html](http://publib.boulder.ibm.com/infocenter/wmqv7/v7r0m0/index.jsp?topic=%2Fcom.ibm.mq.java.doc%2Fcom%2Fibm%2Fmq%2FMCQ.html/).

### Get MQMD Fields
Select this check box to set one or more message descriptors by adding new fields for MQMD(message queuing message descriptor) in the **Parameters** table:

**Field Name:** Select one or more message descriptors from the list to retrieve header information of the message.

**Reference Column Name:** The header and properties information of the message.

For further information, see [http://publib.boulder.ibm.com/infocenter/wmqv7/v7r0m0/index.jsp?topic=%2Fcom.ibm.mq.csqzak.doc%2FfFr13040.htm](http://publib.boulder.ibm.com/infocenter/wmqv7/v7r0m0/index.jsp?topic=%2Fcom.ibm.mq.csqzak.doc%2FfFr13040.htm).
### tMomInput

Include Header

Select this check box to specify the header of the message:

- **MQRFH2 fixed Portion**: Select this check box and click the plus button to add one or more lines to specify the **Version**, **Encoding**, **Format**, **Flags**, **NameValueCCSID** and **CodedCharSetId** as needed for the fixed portion of MQRFH2 header.

- **MCD folder**: Select this check box and click the plus button to add one or more lines to specify the fields and the reference column names for the properties that describe the format of the message.

- **JMS folder**: Select this check box and click the plus button to add one or more lines to specify the fields and the reference column names for the transportation of JMS header fields and JMSX properties.

- **USR folder**: Select this check box and click the plus button to add one or more lines to specify the fields and the reference column names for the transportation of application-defined properties associated with the message.

Available when **WebSphere MQ** is selected in the **MQ Server** list.

### Set Cipher Suite

Select this check box to enable the Cipher Suite list from which you can specify the Cipher Suite to be used with WebSphere MQ SSL.

For further information about Cipher Suite, see [CipherSpecs and their equivalent CipherSuites supported by IBM WebSphere MQ](http://publib.boulder.ibm.com/infocenter/wmbhelp/v6r1m0/index.jsp).

Available when **WebSphere MQ** is selected in the **MQ Server** list.

### Custom Cipher Suite

Select this check box to allow you to customize Cipher Suite.

- **IBM Cipher Mappings**: Use the IBM Java Cipher Suite to IBM MQ Cipher Spec Mappings.

- **Oracle Cipher Mappings**: Use the Oracle Cipher Suite to IBM MQ Cipher Spec Mappings.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as a start component. It must be linked to an output component.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your MQ Server connection dynamically from multiple connections planned in your Job.  
The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
| Limitation | Make sure the relevant ActiveMQ, JBoss Messaging or Websphere MQ server is launched.  
This component requires installation of its related jar files. |

### Asynchronous communication via a MOM server

This scenario is made of two Jobs. The first Job posts messages on a JBoss server queue and the second Job fetches the message from the server.

### Configuring and executing the first Job

#### About this task

In the first Job, a string message is created using a tRowGenerator and put on a JBoss server using a tMomOutput. An intermediary tLogRow component displays the flow being passed.

#### Procedure

1. Drop the three components required for the first Job from the Palette onto the design workspace and right-click to connect them using a Main row link.
2. Double-click on **tRowGenerator** to set the schema to be randomly generated.

![Schema.png](attachment://Schema.png)

3. Set just one column called **message**. This is the message to be put on the MOM queue.

4. This column is of **String** type and is nullable. To produce the data, use a preset function which concatenates randomly chosen ascii characters to form a 6-char string. This function is `getAsciiRandomString`. Click the Preview button to view a random sample of data generated.

5. Set the **Number of rows to be generated** to **10**.

   Click **OK** to validate.

6. The **tLogRow** is only used to display an intermediary state of the data to be handled. In this example, it doesn't require any specific configuration.

7. Then select the **tMomOutput** component.

   ![MQ server configuration.png](attachment://MQ server configuration.png)

   In this case, the **MQ server** to be used is **JBoss**.

   In the **Host** and **Port** fields, fill in the relevant connection information.

8. Select the **Message type** from the list. The message can be of **Queue** or **Topic** type. In this example, select the **Queue** type from the list.

9. In the **To** field, type in the message source information strictly respecting the syntax expected by the server. This should match the Message Type you selected, such as: `queue/A`.

   ![Note:](attachment://Note.png)

   **Note:**

   The message name is case-sensitive, therefore `queue/A` and `Queue/A` are different.

10. Then click **Sync Columns** to pass on the schema from the preceding component. The schema being read-only, it cannot be changed. The data posted onto the MQ comes from the first schema column encountered.

11. Press **F6** to execute the Job and view the data flow being passed on in the console, thanks to the **tLogRow** component.
Configuring and executing the second Job

About this task

Then set the second Job in order to fetch the queuing messages from the MOM server.

Procedure

1. Drop the tMomInput component and a tLogRow from the Palette to the design workspace.

2. Select the tMomInput to set the parameters.

   - **Keep Listening**: On
   - **Sleeping time (in sec)**: 5
   - **MQ server**: JBoss Messaging
   - **Host**: 10.42.10.96
   - **Port**: 1099
   - **Message From**: queue/A
   - **Message Type**: CurQueue
   - **Schema**: Built-In

3. Select the **MQ server** from the list. In this example, a JBoss messaging server is used.
4. Set the server **Host** and **Port** information.
5. Set the **Message From** and the **Message Type** to match the source and type expected by the messaging server.
6. The **Schema** is read-only and is made of two columns: **From** and **Message**.
7. Select the **Keep listening** check box and set the verification frequency to 5 seconds.

   **Note:**

   When using the **Keep Listening** option, you'll need to kill the Job to end it.

8. No need to change any default setting from the tLogRow.
9. Save the Job and run it (when launching for the first time or if you killed it on a previous run).
The messages fetched on the server are displayed on the console.

Transmitting XML files via a MOM server

This scenario describes a five-component Job composed of two subJobs that sends XML files from a local folder to a MOM queue, and then fetches the files from the MOM queue and displays the contents of the files on the console.

Dropping and links the components

Procedure

1. From the Palette, drop the following components one after another onto the design workspace: tFileList, tFileInputXML, tMomOutput, tMomInput, and tLogRow.
2. Connect tFileList to tFileInputXML using a Row > Iterate link, and connect tFileInputXML to tMomOutput using a Row > Main link to form the first subJob. This subJob will read each XML file in a given folder and send it to a MOM queue.
3. Connect tMomInput to tLogRow using a Row > Main link to form the second subJob. This subJob will fetch the XML files from MOM queue and display the file contents on the console.
4. Connect `tFileInputXML` to `tMomInput` using a `Trigger > On Component Ok` connection to link the two subjobs.

**Configuring the first subJob**

**Configuring the input components**

**Procedure**

1. Double-click the `tFileList` component to open its **Basic settings** view.

   ![tFileList component settings](image)

2. In the **Directory** field, enter the path to the directory to read XML files from, or browse to the path by clicking the `...` button next to the field.

3. Select **Use Glob Expressions as Filemask** check box, add a new line in the **Files** field by clicking the `[+]` button, and enter `"*.xml"` as the file mask so that all XML files in the directory will be used. Keep all the other settings as they are.

4. Double-click the `tFileInputXML` component to open its **Basic settings** view.
5. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.

![Schema dialog box](image)

6. Click the [+] button to add a column, give it a name, **message** in this example, and select **Document** from the **Type** list to handle XML format files. Then, click **OK** to close the dialog box.

7. In the **File name/Stream** field, press **Ctrl+Space** to access the global variable list, and select **tFileList_1.CURRENT_FILEPATH** to loop on the context files' directory.

8. In the **Loop XPath query** fields, enter "/*" to define the root as the loop node of the input files' structure; in the **Mapping** table, fill the **XPath query** column with "." to extract all data from context node of the source files, and select the **Get Nodes** check box to build a **Document** type data flow.

**Configuring the tMomOutput component**

**Procedure**

1. Double-click the **tMomOutput** component to open its **Basic settings** view.
2. Select **WebSphere MQ** from the **MQ server** list, and enter the host name or IP address of the MQ server and the port number.

3. Enter the login authentication information in the **Username** and **Password** fields, and enter the channel name of the transmission queue in the **Channel** field.

4. As we are handling file messages, select **Text Message** from the **Message Body Type** list.

5. Click **Sync columns** to retrieve the schema structure from the preceding component.

6. Fill in the queue manager and message queue details in the corresponding fields, and leave the other settings as they are.

**Configuring the second subJob**

**Procedure**

1. Double-click the **tMomInput** component to open its **Basic settings** view.

2. Set the basic parameters of the component using the same settings you have done in the **tMomOutput** component, including the MQ server details, login authentication details, channel, message body type, queue manager and message queue.

3. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.
4. From the **Type** list for the **message** column, select **Document** to handle XML format files, and then click **OK** to close the dialog box.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.
   The XML files in the specified folder are written to the message queue and then retrieved from the queue. The contents of the files are displayed on the console.

**tMomMessageIdList**

Fetches a message ID list from a queue on a Message-Oriented middleware system and passes it to the next component.

tMomMessageIdList makes it possible to iterate on certain message IDs. It is usually used with tMomInput, for more information, see tMomInput Standard properties on page 2256.

**tMomMessageIdList Standard properties**

These properties are used to configure tMomMessageIdList running in the Standard Job framework.

The Standard tMomMessageIdList component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined. When a Job contains a parent Job and a child Job, the list displayed presents only the connection components in the same Job level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>MQ Server</td>
<td>Select the MOM server to be used from the list. According to the server selected, the parameters required differ slightly.</td>
</tr>
<tr>
<td>Host/Port</td>
<td>Fill in the Host name or IP address of the MOM server and Port.</td>
</tr>
<tr>
<td>Channel</td>
<td>Channel on the queue.</td>
</tr>
<tr>
<td>Queue Manager</td>
<td>Fill in the server driver details.</td>
</tr>
<tr>
<td>Message Queue</td>
<td>Source of the message.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box. <strong>CURRENT_MESSAGE_ID</strong>: the identifier of the current message. This is a Flow variable and it returns a string. <strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
</table>

2271
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as an input component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Make sure the relevant Websphere server is launched.</td>
</tr>
<tr>
<td></td>
<td>This component requires installation of its related jar files.</td>
</tr>
</tbody>
</table>

### Related scenario

For a related scenario, see tMomInput on page 2256.
**tMomOutput**

Adds a message to a Message-Oriented Middleware system queue in order for it to be fetched asynchronously.

tMomOutput makes it possible to set up asynchronous communications via a MOM server.

For further information about the messaging brokers supported by this component, see [Messaging brokers supported by Talend messaging components](#).

**tMomOutput Standard properties**

These properties are used to configure tMomOutput running in the Standard Job framework.

The Standard tMomOutput component belongs to the Internet family.

The component in this framework is available in all [Talend products](#).

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, <strong>Component List</strong> presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td>Failover</td>
<td>Select this check box to use the ActiveMQ failover transport. For more information about the failover transport, see <a href="#">Failover Transport Reference</a>. This check box is available only when ActiveMQ is selected from the MQ server list and the Static Discovery check box is cleared.</td>
</tr>
<tr>
<td>Static Discovery</td>
<td>Select this check box to use the ActiveMQ static transport discovery mechanism. For more information about the static transport, see <a href="#">Static Transport Reference</a>. This check box is available only when ActiveMQ is selected from the MQ server list and the Failover check box is cleared.</td>
</tr>
<tr>
<td>URI parameters</td>
<td>Enter the URI parameters. This field is available only when the Failover or Static Discovery check box is selected.</td>
</tr>
<tr>
<td>MQ Server</td>
<td>Select the type of the MQ server(s) to be connected from the list: <a href="#">ActiveMQ</a>, <a href="#">JBoss Messaging</a>, or <a href="#">WebSphere MQ</a>. According to the server type selected, the parameters required differ slightly.</td>
</tr>
<tr>
<td>Use SSL Transport</td>
<td>Select this check box to use the ActiveMQ SSL transport. For more information about the SSL transport, see <a href="#">SSL Transport Reference</a>. This check box is available only when ActiveMQ is selected from the MQ server list.</td>
</tr>
<tr>
<td>Host</td>
<td>Enter the host name or IP address of the MQ server.</td>
</tr>
<tr>
<td>------------</td>
<td>-----------------------------------------------------</td>
</tr>
<tr>
<td>Port</td>
<td>Enter the listening port of the MQ server.</td>
</tr>
</tbody>
</table>
| Username and Password | Enter the user authentication credentials.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Channel    | Specify the name of the channel through which the connection is established. The default value is DC.SVRCONN. This field is available only when WebSphere MQ is selected from the MQ server list. |
| To         | Type in the message destination, respecting the syntax required by the server; this must include the type and name of the target folder, e.g.: queue/A or topic/testtopic. Note that this field is case-sensitive.  
This field is available only when ActiveMQ or JBoss Messaging is selected from the MQ Server list. |
| Message Type | Select the message type: either Topic or Queue.  
This list is available only when ActiveMQ or JBoss Messaging is selected from the MQ Server list. |
| Message Body Type | Select the message body type: Text Message, Bytes Message or Map Message. |
| Schema and Edit Schema | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component.  
In the context of tMomOutput usage, the schema is read-only but will change according to the incoming schema. Only one-column schema is expected by the server to contain the Messages. |
| QueueManager | Specify the name of the queue manager to which the connection is established.  
This field is available only when WebSphere MQ is selected from the MQ server list. |
| MessageQueue | Enter the name of the message queue into which message queueing applications can put messages.  
This field is available only when WebSphere MQ is selected from the MQ server list. |
| Set Transacted | Select this check box to transact the session. For further information about this parameter, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.  
Note that selecting this check box will ignore the settings in the Acknowledgement Mode list in the Advanced settings view of tMomInput. |
| Is using message id to set | Select this check box to set messages according to their ids. |
### Advanced settings

**Additional options**

Define the additional transport options in the table. This table is available only if you select the Failover or Static Discovery check box in the Basic settings view.

- **Option name**: the name of the option.
- **Option value**: the value of the option.

For example, enter `maxReconnectAttempts` in the Option name field and then `0` in the Option value field so that no attempt is made to retry the connection when no server is available.

For more information about the failover transport options, see [Failover Transport Reference](#).

For more information about the static discovery transport options, see [Static Transport Reference](#).

**Delivery Mode**

Select a delivery mode supported by JMS:

- **Not Persistent**: This delivery mode does not require that the message be logged to stable storage.
- **Persistent**: This delivery mode requires that the message be logged to stable storage as part of the client’s send operation.

(Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.)

**Set Jms Header**

Select this check box to send the Jms headers through the mapping from Jms fields onto MQ Series fields on the MQ server. When this check box is checked, you can specify the header name and the header value in the line(s) you added by clicking the plus button in the Parameters table. For further information about the usage of Jms headers, see [https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqqwzaw07.pdf](https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqqwzaw07.pdf).

(Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.)

**Set Jms Properties**

Select this check box to send the Jms properties mapped onto MQMD fields on the MQ server. When this check box is checked, you can specify the property name, the property type and the property value in the line(s) you added by clicking the plus button in the Parameters table. For further information about the usage of Jms properties, see [https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqqwzaw07.pdf](https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqqwzaw07.pdf).

(Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.)

**Use format**

Select this check box to specify the WebSphere message format in the WebSphere Message Format field. The default format is `MQSTR`.

---

This check box is available only when **Text Message** or **Bytes Message** is selected from the Message Body Type list.
For further information about WebSphere message format, see http://publib.boulder.ibm.com/infocenter/wtxdoc/v8r2m0/index.jsp?topic=com.ibm.websphere.dtx.adapibmmsg.doc/references/r_ibmmq_Message_Format_FORMAT.htm.

(Available when WebSphere MQ is selected in the MQ Server list.)

<table>
<thead>
<tr>
<th>Set MQMD Fields</th>
<th>Select this check box to enable the Parameters table in which you can specify the value of the MQMD fields. This check box is available only when WebSphere MQ is selected from the MQ Server list.</th>
</tr>
</thead>
</table>
| Parameters     | Specify the value of the MQMD fields.  
|                | • Field Name: Select an MQMD field from the list.  
|                | • Field Value: Enter the value of the corresponding MQMD field.  
|                | This table is available only when the Set MQMD Fields check box is selected.  
|                | For more information about the MQMD fields, see Fields for MQMD. |

| Include Header | Select this check box to specify the header of the message:  
|                | MQRFH2 fixed Portion: Select this check box and click the plus button to add one or more lines to specify the Version, Encoding, Format, Flags, NameValueCCSID and CodedCharSetId as needed for the fixed portion of MQRFH2 header.  
|                | MCD folder: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the properties that describe the format of the message.  
|                | JMS folder: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the transportation of JMS header fields and JMSX properties.  
|                | USR folder: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the transportation of application-defined properties associated with the message.  
|                | Available when WebSphere MQ is selected in the MQ Server list. |

| Set Cipher Suite | Select this check box to enable the Cipher Suite list from which you can specify the Cipher Suite to be used with WebSphere MQ SSL.  
|                 | For further information about Cipher Suite, see CipherSpecs and their equivalent CipherSuites supported by IBM WebSphere MQ.  
|                 | Available when WebSphere MQ is selected in the MQ Server list. |
**Custom Cipher Suite**
Select this check box to allow you to customize Cipher Suite.

**IBM Cipher Mappings:** Use the IBM Java Cipher Suite to IBM MQ Cipher Spec Mappings.

**Oracle Cipher Mappings:** Use the Oracle Cipher Suite to IBM MQ Cipher Spec Mappings.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

---

### Global Variables

**Global Variables**

- **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- **NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

  To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

  For further information about variables, see **Talend Studio User Guide**.

---

### Usage

**Usage rule**
This component must be linked to an input or intermediary component.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your MQ Server connection dynamically from multiple connections planned in your Job.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2472 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 495. For more information on **Dynamic settings** and context variables, see **Talend Studio User Guide**.

**Limitation**
Make sure the relevant Websphere MQ, JBoss Messaging or ActiveMQ server is launched.

This component requires installation of its related jar files.
Related scenario

For a related scenario, see tMomInput on page 2256.
**tMomRollback**

Cancels the transaction committed in the MQ Server.

**tMomRollback Standard properties**

These properties are used to configure tMomRollback running in the Standard Job framework.

The Standard tMomRollback component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the component used in your Job.</th>
</tr>
</thead>
</table>
| Backout messages to backout queue (WebsphereMQ) | Select this check box to backout the messages to the backout queue defined in the Websphere MQ manager when the backout count reaches the configured threshold which is a property of the queue in the Websphere MQ server.  
  - If a tMomConnection component is selected from Component List, the messages processed by all tMomInput components that reuses the connection created by the selected tMomConnection component will be backouted.  
  - If a tMomInput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomInput component is cleared, the messages processed by the selected tMomInput component will be backouted.  
  - If a tMomInput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomInput component is selected, the messages processed by all tMomInput components that reuses the same connection the selected tMomInput component reused will be backouted.  
  - If a tMomOutput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomOutput component is cleared, no messages will be backouted.  
  - If a tMomOutput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomOutput component is selected, the messages processed by all tMomInput components that reuses the same connection the selected tMomOutput component reused will be backouted.  

Note that this check box works only when the Commit (delete message after read from the queue), Backout messages to input queue, Backout messages to backout queue (when backoutCount of message reach the threshold value), and Browse message check boxes of all tMomInput components in the same Job are cleared.
Close Connection

Clear this check box to continue to use the selected connection once the component has performed its task.

Advanced settings

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component is more commonly used with other tMom* components, especially with the **tMomConnection** and **tMomCommit** components.

Related scenario

For a similar scenario, see *Rollback from inserting data in mother/daughter tables* on page 2455.
**tMondrianInput**

Executes a multi-dimensional expression (MDX) query corresponding to the dataset structure and schema definition.

tMondrianInput reads data from relational databases and produces multidimensional data sets based on an MDX query. Then it passes on the multidimensional dataset to the next component via a Main row link.

**tMondrianInput Standard properties**

These properties are used to configure tMondrianInput running in the Standard Job framework. The Standard tMondrianInput component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>

</tr>
</tbody>
</table>
completion and choose this schema metadata again in the **Repository Content** window.

| **Built-in** | The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |

**Catalog**
Path to the catalog (structure of the data warehouse).

**MDX Query**
Type in the MDX query paying particularly attention to properly sequence the fields in order to match the schema definition and the data warehouse structure.

**Encoding**
Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

### Advanced settings

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**
This component covers MDX queries for multi-dimensional datasets.

**Limitation**
This component requires installation of its related jar files.
Extracting multi-dimensional datasets from a MySQL database (Cross-join tables)

This Job extracts multi-dimensional datasets from relational database tables stored in a MySQL base. The data are retrieved using a multidimensional expression (MDX query). Obviously you need to have to know the structure of your data, or at least have a structure description (catalog) as a reference for the dataset to be retrieved in the various dimensions.

Setting up the Job

Procedure

1. Drop **tMondrianInput** and **tLogRow** from the Palette to the design workspace.
2. Connect the Mondrian connector to the output component using a **Row Main** connection.

Setting up the DB connection

Procedure

1. Double-click the **tMondrianInput** component to display its **Basic settings** view.

   - **DB Type**: MySQL
   - **Property Type**: Built-In
   - **Host**: localhost
   - **Port**: 3306
   - **Database**: FoodMart
   - **User Name**: root
   - **Password**: ****
   - **Schema**: Built-In
   - **Catalog**: "H:MySQL/Input/FoodMart.xml"
   - **MDX query**:

     ```sql
     select
     [Measures].[Unit Sales], [Measures].[Store Cost], [Measures].[Store Sales] on columns,
     CrossJoin(
         [Promotion Media].[All Media].[Radio], [Promotion Media].[All Media].[TV], [Promotion Media].[All Media].[Sunday Paper],
         [Promotion Media].[All Media].[Street Handout],
         [Product].[All Products].[Drink].children) on rows
     where (([Time] [1997]))
     ```

   - **Encoding Type**: ISO-8859-15

2. In **DB type** field, select the relational database you are using with Mondrian.
3. Select the relevant Repository entry as **Property type**, if you store your DB connection details centrally. In this example the properties are built-in.
4. Fill out the details of connection to your DB: **Host**, **Port**, **Database** name, **User Name** and **Password**.
5. Select the relevant **Schema** in the Repository if you store it centrally. In this example, the schema is to be set (built-in).
Configuring the DB query

Procedure

1. The relational database we want to query contains five columns: `media`, `drink`, `unit_sales`, `store_cost` and `store_sales`.
2. The query aims at retrieving the `unit_sales`, `store_cost` and `store_sales` figures for various `media` / `drink` using an MDX query such as in the example below:

   **CrossJoin Example 1**

   The current slicer is 1997.

<table>
<thead>
<tr>
<th></th>
<th>Unit Sales</th>
<th>Store Cost</th>
<th>Store Sales</th>
</tr>
</thead>
<tbody>
<tr>
<td>Radio</td>
<td>Alcoholic Beverages</td>
<td>75</td>
<td>70.40</td>
</tr>
<tr>
<td></td>
<td>Beverages</td>
<td>97</td>
<td>75.70</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>54</td>
<td>36.75</td>
</tr>
<tr>
<td>TV</td>
<td>Alcoholic Beverages</td>
<td>76</td>
<td>70.99</td>
</tr>
<tr>
<td></td>
<td>Beverages</td>
<td>188</td>
<td>167.00</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>68</td>
<td>45.19</td>
</tr>
<tr>
<td>Sunday Paper</td>
<td>Alcoholic Beverages</td>
<td>148</td>
<td>128.97</td>
</tr>
<tr>
<td></td>
<td>Beverages</td>
<td>197</td>
<td>161.81</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>85</td>
<td>54.75</td>
</tr>
<tr>
<td>Street Handout</td>
<td>Alcoholic Beverages</td>
<td>158</td>
<td>121.14</td>
</tr>
<tr>
<td></td>
<td>Beverages</td>
<td>270</td>
<td>201.29</td>
</tr>
<tr>
<td></td>
<td>Dairy</td>
<td>84</td>
<td>50.25</td>
</tr>
</tbody>
</table>

3. Back on the **Basic settings** tab of the `tMondrianInput` component, set the **Catalog** path to the data warehouse. This catalog describes the structure of the warehouse.
4. Then type in the MDX query such as:

```mdx
"select
    { [Measures].[Unit Sales], [Measures].[Store Cost], [Measures].[Store Sales] } on columns,
    CrossJoin(
        { [Promotion Media].[All Media].[Radio],
          [Promotion Media].[All Media].[TV],
          [Promotion Media].[All Media].[Sunday Paper],
          [Promotion Media].[All Media].[Street Handout] },
        [Product].[All Products].[Drink].children) on rows
from Sales
where ([Time].[1997])"
```

5. Eventually, select the **Encoding** type on the list.

**Job execution**

**Procedure**

1. Select the **tLogRow** component and select the **Print header** check box to display the column names on the console.

2. Then press **F6** to run the Job.

```
Starting job Mondrian at 15:31 08/01/2008
media  drink  unit sales  store cost  store sales
Promotion Media.[All Media].[Radio] [Product].[All Products].[Drink] [Alcoholic beverages] 76.0 [70.3977] [100.62]
Promotion Media.[All Media].[Radio] [Product].[All Products].[Drink] [Beverages] 97.0 [75.7016] [186.03]
Promotion Media.[All Media].[Radio] [Product].[All Products].[Drink] [Dairy] 54.0 [36.7474] [83.03]
Promotion Media.[All Media].[TV] [Product].[All Products] [Drink] [Alcoholic beverages] 76.0 [70.3977] [100.62]
Promotion Media.[All Media].[TV] [Product].[All Products] [Drink] [Beverages] 189.0 [167.0025] [419.14]
Promotion Media.[All Media].[TV] [Product].[All Products] [Drink] [Dairy] 46.0 [45.1404] [119.58]
Promotion Media.[All Media].[Sunday Paper] [Product].[All Products] [Drink] [Alcoholic beverages] 148.0 [120.4956] [316.69]

Promotion Media.[All Media] [Street Handout] [Product].[All Products] [Drink] [Beverages] 270.0 [201.2015] [520.55]
Promotion Media.[All Media] [Street Handout] [Product].[All Products] [Drink] [Dairy] 180.0 [150.2430] [318.32]
Log Mondrian ended at 15:31 08/01/2008. [exit code=0]
```

**Results**

The console shows the result of the **unit_sales**, **store_cost** and **store_sales** for each type of **Drink** (**Beverages, Dairy, Alcoholic beverages**) crossed with each media (**TV, Sunday Paper, Street handout**) as shown previously in a table form.
Imports data files in different formats (CSV, TSV or JSON) into the specified MongoDB database so that the data can be further processed.

**tMongoDBBulkLoad Standard properties**

These properties are used to configure tMongoDBBulkLoad running in the Standard Job framework.

The Standard tMongoDBBulkLoad component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **MongoDB directory** | Fill in this field with the MongoDB home directory. |
| **Use local DB path** | Select this check box to provide the information of the local database that you want to use. MongoDB V3.0 and onward versions do not support this feature.
- **Local DB path**: type in the path to the local database specified when starting the MongoDB server. |
| **Use replica set address** | Select this check box to define a replica set to be connected.
- **Replica set name**: specify the name of the replica set.
- **Replica address**: specify multiple MongoDB database servers for failover as needed. Note that if you leave the replica host or replica port unspecified, their default values localhost and 27017 will be used. |
<p>| <strong>Server</strong> | Hostname or IP address of the database server. Note that the default value localhost will be used if the server is not specified. |</p>
<table>
<thead>
<tr>
<th><strong>tMongoDBBulkLoad</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong>&lt;br&gt;Listening port of the database server. Note that the default value 27017 will be used if the port is not specified.&lt;br&gt;This field is available only when the <strong>Use replica set address</strong> check box is not selected.</td>
</tr>
<tr>
<td><strong>Database</strong>&lt;br&gt;Type in the name of the database to import data to.</td>
</tr>
<tr>
<td><strong>Collection</strong>&lt;br&gt;Type in the name of the collection to import data to.</td>
</tr>
<tr>
<td><strong>Use SSL connection</strong>&lt;br&gt;Select this check box to enable the SSL or TLS encrypted connection.&lt;br&gt;Then you need to use the <strong>tSetKeystore</strong> component in the same Job to specify the encryption information.&lt;br&gt;For further information about <strong>tSetKeystore</strong>, see <strong>tSetKeystore</strong> on page 3496.&lt;br&gt;Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td><strong>Drop collection if exist</strong>&lt;br&gt;Select this check box to remove the collection if it already exists.</td>
</tr>
<tr>
<td><strong>Required authentication</strong>&lt;br&gt;Select this check box to enable the database authentication.&lt;br&gt;Among the mechanisms listed on the <strong>Authentication mechanism</strong> drop-down list, the <strong>NEGOTIATE</strong> one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.&lt;br&gt;For details about the other mechanisms in this list, see <strong>MongoDB Authentication</strong> from the MongoDB documentation.</td>
</tr>
<tr>
<td><strong>Set Authentication database</strong>&lt;br&gt;If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the <strong>Authentication database</strong> field that is displayed.&lt;br&gt;For further information about the MongoDB Authentication database, see <strong>User Authentication database</strong>.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong>&lt;br&gt;DB user authentication data.&lt;br&gt;To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.&lt;br&gt;Available when the <strong>Required authentication</strong> check box is selected.&lt;br&gt;If the security system you have selected from the <strong>Authentication mechanism</strong> drop-down list is Kerberos, you need to enter the <strong>User principal</strong>, the <strong>Realm</strong> and the <strong>KDC server</strong> fields instead of the <strong>Username</strong> and the <strong>Password</strong> fields.</td>
</tr>
</tbody>
</table>
### Data file
- **Type in the full path of the file from which the data will be imported** or click the [...] button to browse to the desired data file.
- **Make sure that the data file is in standard format.** For example, the fields in CSV files should be separated with commas.

### File type
- **Select the proper file type from the list.** CSV, TSV and JSON are supported.

### The JSON file starts with an array
- **Select this check box to allow tMongoDBBulkload to read the JSON files starting with an array.**
- This check box appears when the **File type** you have selected is JSON.

### Action on data
- **Select the action that you want to perform on the data.**
  - **Insert:** Insert the data into the database.
    - **Note that when inserting data from CSV or TSV files into the MongoDB database, you need to specify fields either by selecting the First line is header check box or defining them in the schema.**
  - **Upsert:** Insert the data if they do not exist or update the existing data.
    - **Note that when upserting data into the MongoDB database, you need to specify a list of fields for the query portion of the upsert operation.**

### Upsert fields
- **Customize the fields that you want to upsert as needed.**
- This table is available when you select **Upsert** from the **Action on data** list.

### First line is header
- **Select this check box to use the first line in CSV or TSV files as a header.**
- This check box is available only when you select CSV or TSV from the **File type** list.

### Ignore blanks
- **Select this check box to ignore the empty fields in CSV or TSV files.**
- This check box is available only when you select CSV or TSV from the **File type** list.

### Print log
- **Select this check box to print logs.**

### Advanced settings

#### Additional arguments
- **Complete this table to use the additional arguments as required.**
- For example, you can use the argument `"--jsonArray"` to accept the import of data expressed with multiple MongoDB documents within a single JSON array. For more information about the additional arguments, go to [http://docs.mongodb.org/manual/reference/program/mongoimport/](http://docs.mongodb.org/manual/reference/program/mongoimport/) and read the description of options.
### tMongoDBBulkLoad

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at a component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used together with the tMongoDBInput component to check if the data is imported as expected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>The MongoDB client tool needs to be installed on the machine where Jobs using this component are executed.</td>
</tr>
</tbody>
</table>

### Importing data into MongoDB database

This scenario applies only to [Talend products with Big Data](#).

The following scenario describes a Job that firstly imports data from a CSV file into the specified MongoDB collection, then reads data from the MongoDB collection to check if the import is successful, next continues to import data from a JSON file with the same data structure into the same MongoDB collection, and finally displays the data from the MongoDB collection to demonstrate that the data from the JSON file is also imported successfully.
Dropping and linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: two tMongoDBBulkLoad components, two tMongoDBInput components, and two tLogRow components.

2. Connect the first tMongoDBBulkLoad to the first tMongoDBInput using a Trigger > OnSubjobOk link.

3. Connect the first tMongoDBInput to the first tLogRow using a Row > Main link.

4. Repeat the two steps above to connect the second tMongoDBBulkLoad to the second tMongoDBInput, and the second tMongoDBInput to the second tLogRow.

5. Connect the first tMongoDBInput to the second tMongoDBBulkLoad using a Trigger > OnSubjobOk link.

6. Label the two tLogRow components to better identify the data displayed on the console.
Configuring the components

Importing data from a CSV file

Procedure

1. Double-click the first tMongoDBBulkLoad component to open its Basic settings view in the Component tab.

![tMongoDBBulkLoad component](image)

2. In the MongoDB directory field, type in the MongoDB home directory. In this example, it is D:/MongoDB.

3. In the Server and Port fields, fill in the information required for the connection to MongoDB. In this example, type in localhost and 27017.

4. In the Database field, type in the database to import data to, bookstore in this example.

5. In the Collection field, type in the collection to import data to, books in this example.

6. Select the Drop collection if exist check box to remove the specified collection if it already exists.

7. Browse to the desired data file from which you want to import data. In this example, it is D:/Input/books.csv, which is a standard CSV file containing four columns: id, title, author, and category.

<table>
<thead>
<tr>
<th>id</th>
<th>title</th>
<th>author</th>
<th>category</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Computer Networks</td>
<td>Larry Peterson</td>
<td>Computer Science</td>
</tr>
<tr>
<td>2</td>
<td>David Copperfield</td>
<td>Charles Dickens</td>
<td>Language&amp;Literature</td>
</tr>
<tr>
<td>3</td>
<td>Life of Pi</td>
<td>Yann Martel</td>
<td>Language&amp;Literature</td>
</tr>
</tbody>
</table>

8. Select CSV from the File type list.

9. Select Insert from the Action on data list.

10. Select the First line is header check box to use the first line in the CSV file as a header.

11. Select the Ignore blanks check box to ignore the blank fields (if any) in the CSV file.
Validating that the CSV file is imported successfully

Procedure

1. Double-click the first tMongoDBInput component to open its Basic settings view in the Component tab.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, fill in the information required for the connection to MongoDB. In this example, type in localhost and 27017.

4. In the Database field, type in the database from which the data will be read, bookstore in this example.

5. In the Collection field, type in the collection from which the data will be read, books in this example.

6. Click Edit schema to define the data structure to be read from the MongoDB collection.
7. In the Mapping table, the Column field is automatically populated with the defined schema. You do not need to fill in the Parent node path column.

8. Double-click the first tLogRow component to open its Basic settings view in the Component tab.

9. In the Mode area, select Table (print values in cells of a table).

**Importing data from a JSON file**

**Procedure**

1. Double-click the second tMongoDBBulkLoad component to open its Basic settings view in the Component tab.
2. In the MongoDB directory field, type in the MongoDB home directory. In this example, it is D:/MongoDB.

3. In the Server and Port fields, fill in the information required for the connection to MongoDB. In this example, type in localhost and 27017.

4. In the Database field, type in the target database to import data, bookstore in this example.

5. In the Collection field, type in the target collection to import data, books in this example.

6. Browse to the desired data file from which you want to import data. Here, select books.json.

   ```json
   { "id": "4", "title": "Les Miserables", "author": "Victor Hugo", "category": "Language&Literature" }
   { "id": "5", "title": "Advanced Database Systems", "author": "Carlo Zaniolo", "category": "Database" }
   ```

7. Select JSON from the File type list.

8. Select Insert from the Action on data list.

9. Click the Advanced settings tab to define the additional arguments as needed.

   In this example, add the argument " --jsonArray" to accept the imported data within a single JSON array.
Validating that the JSON file is imported successfully

Procedure

1. Repeat Step 1 through Step 7 described in the procedure Validating that the CSV file is imported successfully on page 2292 to configure the second tMongoDBInput component.

2. Repeat Step 8 through Step 9 described in the procedure Validating that the CSV file is imported successfully on page 2292 to configure the second tLogRow component.

Saving and executing the Job

Procedure

1. Press Ctrl + S to save the Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.
The data from the collection `books` in the MongoDB database `bookstore` is displayed on the console, which contains the data imported from both the CSV file `books.csv` and the JSON file `books.json`. 
tMongoDBClose

Closes a connection to the MongoDB database.

**tMongoDBClose Standard properties**

These properties are used to configure tMongoDBClose running in the Standard Job framework. The Standard tMongoDBClose component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component list | Select the tMongoDBConnection component in the list if more than one connection is created for the current Job. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with other MongoDB components, especially tMongoDBConnection. |

**Related scenario**

For a related scenario, see Creating a collection and writing data to it on page 2340.
tMongoDBConnection

Creates a connection to a MongoDB database and reuse that connection in other components.
tMongoDBConnection opens a connection to a database in order that a transaction may be made.

**tMongoDBConnection Standard properties**

These properties are used to configure tMongoDBConnection running in the Standard Job framework.
The Standard tMongoDBConnection component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

</tr>
</tbody>
</table>
For further information about the MongoDB Authentication database, see User Authentication database.

### Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at a component level.</th>
</tr>
</thead>
</table>

| No query timeout | Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method.  
A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/). |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is generally used with other MongoDB components, particularly tMongoClose. |
Related scenario

For a related scenario, see Creating a collection and writing data to it on page 2340.
tMongoDBGridFSDelete

Automates the delete action over specific files in MongoDB GridFS.

tMongoDBGridFSDelete connects to a given MongoDB GridFS system, executes a user-defined query to select specific files and deletes these files from this system.

**tMongoDBGridFSDelete Standard properties**

These properties are used to configure tMongoDBGridFSDelete running in the Standard Job framework.

The Standard tMongoDBGridFSDelete component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
</tbody>
</table>

| Use an existing connection            | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
|                                      | Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |

| Use replica set address or multiple query routers | Select this check box to show the Server addresses table. |
|                                                | In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to. |

| Server and Port                           | IP address and listening port of the database server. |
|                                          | Available when the Use replica set address check box is not selected. |
|                                          | Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server. |

| Database                                 | Name of the database. |

| Use SSL connection                      | Select this check box to enable the SSL or TLS encrypted connection. |
|                                          | Then you need to use the tSetKeystore component in the same Job to specify the encryption information. |
|                                          | For further information about tSetKeystore, see tSetKeystore on page 3496. |
Note that the SSL connection is available only for the version 2.4+ of MongoDB.

### Set read preference
Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.
If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.
For further information, see MongoDB’s documentation about Replication and its Read preferences.

### Use authentication
Select this check box to enable the database authentication.
Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.
For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

### Set Authentication database
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.
For further information about the MongoDB Authentication database, see User Authentication database.

### Username and Password
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.
Available when the Required authentication check box is selected.
If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

### Bucket
Enter the name of the bucket from which you need to delete files. A bucket of GridFS is similar to a folder.

### Query type
Select the type of the query you want tMongoDBGridFS Delete to perform to select the files to be deleted.
- **Filename**: you need to enter the name of the file to be deleted. This name is the value of the filename attribute of this file. Note that only one name is allowed.
  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.
- **Mongo Query**: enter the query to be used to select the files to be deleted.
The example query, `{}` within double quotation marks provided with `tMongoDBGridFSDelete`, means to select all of the files in a bucket. You can put `{filename:{'$regex': 'REGEX_PATTERN'}}` to apply a regular expression to defining the file names to be used.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).

### Global Variables

**Global Variables**

- **NB_FILE**: the number of files processed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/).

### Usage

**Usage rule**

This component combines MongoDB GridFS connection and data iteration, thus usually used as a single-component subjob to delete selected files from a given bucket in MongoDB GridFS.

It is often connected to the Job using **OnSubjobOk** or **OnComponentOk** link, depending on the context.
Related scenario

For a scenario using tMongoDBGridFSDelete, see Managing files using MongoDB GridFS on page 2319.
tMongoDBGridFSGet

Connects to a MongoDB GridFS system to copy files from it.

tMongoDBGridFSGet copies files from a given MongoDB GridFS system to a local directory and if needs be, renames these files.

**tMongoDBGridFSGet Standard properties**

These properties are used to configure tMongoDBGridFSGet running in the Standard Job framework.
The Standard tMongoDBGridFSGet component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|               | Built-In: No property data stored centrally.  
|               | Repository: Select the repository file where the properties are stored. |

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**Use replica set address or multiple query routers**

Select this check box to show the Server addresses table. In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.

**Server and Port**

IP address and listening port of the database server.
Available when the Use replica set address check box is not selected.

Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.

**Database**

Name of the database.

**Use SSL connection**

Select this check box to enable the SSL or TLS encrypted connection.

Then you need to use the tSetKeystore component in the same Job to specify the encryption information.

For further information about tSetKeystore, see tSetKeystore on page 3496.
Note that the SSL connection is available only for the version 2.4+ of MongoDB.

**Set read preference**
Select this check box and from the **Read preference** drop-down list that is displayed, select the member to which you need to direct the read operations.
If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.
For further information, see MongoDB's documentation about Replication and its Read preferences.

**Required authentication**
Select this check box to enable the database authentication.
Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGOTIATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.
For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

**Set Authentication database**
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.
For further information about the MongoDB Authentication database, see User Authentication database.

**Username and Password**
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.
Available when the **Required authentication** check box is selected.
If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields.

**Bucket**
Enter the name of the bucket you need to read files from. A bucket of GridFS is similar to a folder.

**Query type**
Select the type of the query you want **tmMongoDBGridFSGet** to perform to select the data to be copied.
- **Filename**: you need to enter the name of the file to be copied. This name is the value of the `filename` attribute used by this file. Note that only one name is allowed.
  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.
- **Mongo Query**: enter the query to be used to select the files to be copied.
### tMongoDBGridFSGet

The default query, `{}` within double quotation marks provided with this component, means to select all of the files. You can also apply a regular expression by putting `{'filename':{'$regex':'REGEX_PATTERN'}}` to define the file names to be used.

It is recommended to use your query along with the **Overwrite local files** and the **Use Document ID as output filename** check boxes to avoid any file name conflict issue.

| **Local Folder** | Enter the path to the folder in which the data copied from GridFS is to be written.
| **Overwrite local files** | Select this check box to overwrite the file using the same file name in the local folder being used. Otherwise, an exception will be returned in this type of situation.
| **Use Document ID as output filename** | Select this check box to rename the incoming files on the fly using the values of their object IDs. This allows you keep the files that have the same file names.

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect the log data at the component level.
| **No query timeout** | Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).

### Global Variables

| **Global Variables** | **NB_FILE**: the number of files processed. This is an After variable and it returns an integer.
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/tds-user-guide/latest/tutorials/variables/).
Usage

| Usage rule | This component combines MongoDB GridFS connection and data extraction, thus usually used as a single-component subjob to copy data from GridFS to a user-defined local directory. It is often connected to the Job using OnSubjobOk or OnComponentOk link, depending on the context. |

Related scenario

For a scenario using tMongoDBGridFSGet, see Managing files using MongoDB GridFS on page 2319.
tMongoDBGridFSList

Retrieves a list of files based on a query.
tMongoDBGridFSList iterates on files of a bucket in MongoDB GridFS.

tMongoDBGridFSList Standard properties

These properties are used to configure tMongoDBGridFSList running in the Standard Job framework. The Standard tMongoDBGridFSList component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository. Built-In: No property data stored centrally. Repository: Select the repository file where the properties are stored.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td>Use replica set address or multiple query routers</td>
<td>Select this check box to show the Server addresses table. In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>IP address and listening port of the database server. Available when the Use replica set address check box is not selected. Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3496. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
</tbody>
</table>
**Set read preference**  
Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

**Use authentication**  
Select this check box to enable the database authentication.

Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

**Set Authentication database**  
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database.

**Username and Password**  
DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

**Bucket**  
Enter the name of the bucket in which the files to be listed are stored. A bucket of GridFS is similar to a folder.

**Query**  
Enter the query to be used to select the files to be listed. You need to define how these files are sorted in the list by selecting:

- **Sort by**: these files can be sorted by their *filename* attributes, *uploadDate* attributes or *length* (the *File Size* option) attributes.
- **Sort order**: these files can be sorted in the Ascending or Descending order.

**Advanced settings**

**tStatCatcher Statistics**  
Select this check box to collect the log data at the component level.
No query timeout

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see https://docs.mongodb.org/manual/core/cursors/.

Global Variables

Global Variables

NB_FILE: the number of files processed. This is an After variable and it returns an integer.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

CURRENT_FILEID: the value of the ObjectId (the file ID) attribute of the current file. This is an Flow variable and it returns a string.

CURRENT_FILENAME: the value of the filename attribute of the current file. This is an Flow variable and it returns a string.

CURRENT_FILEUPLOADDATE: the value of the uploadDate attribute of the current file. This is an Flow variable and it returns a date.

CURRENT_FILELENGTH: the value of the length (the size) attribute of the current file. This is an Flow variable and it returns a length.

CURRENT_FILEMD5: the value of the md5 attribute of the current file. This is an Flow variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component combines MongoDB GridFS connection and data iteration, thus usually used as a single-component subtask to list files stored in a given bucket in MongoDB GridFS.

Different lists are returned, each representing an attribute of these files and being stored in a specific global variable as explained above regarding the global variables provided by tMongoDBGridFSList.
Related scenario

For a scenario using `tMongoDBGridFSList`, see Managing files using MongoDB GridFS on page 2319.
tMongoDBGridFSProperties

Obtains information about the properties of given files selected based on a query.
tMongoDBGridFSProperties iterates on files of a bucket in MongoDB GridFS to extract the attributes of these files.

**tMongoDBGridFSProperties Standard properties**

These properties are used to configure tMongoDBGridFSProperties running in the Standard Job framework.

The Standard tMongoDBGridFSProperties component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either **Built-In** or **Repository**.  
|---------------|--------------------------------------|
| **Built-In**: No property data stored centrally.  
| **Repository**: Select the repository file where the properties are stored.  |
| **Use an existing connection** | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.  
| Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.  |
| **Use replica set address or multiple query routers** | Select this check box to show the **Server addresses** table.  
| In the **Server addresses** table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.  |
| **Server and Port** | IP address and listening port of the database server.  
| Available when the **Use replica set address** check box is not selected.  
| Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.  |
| **Database** | Name of the database.  |
| **Use SSL connection** | Select this check box to enable the SSL or TLS encrypted connection.  
| Then you need to use the **tSetKeystore** component in the same Job to specify the encryption information.  
| For further information about **tSetKeystore**, see **tSetKeystore** on page 3496.  |
Note that the SSL connection is available only for the version 2.4+ of MongoDB.

### Set read preference
Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

### Use authentication
Select this check box to enable the database authentication.

Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

### Set Authentication database
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database.

### Username and Password
DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

### Bucket
Enter the name of the bucket in which the files to be used are stored. A bucket of GridFS is similar to a folder.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

The columns of the predefined schema of tMongoDBGridFS Properties represent the default attributes of a GridFS file and the column names are already identical with the attribute names.

- If you want to exclude some attributes from the data flow to be processed in your Job, you can remove the columns corresponding to those attributes from this schema.
- Do not change the names of the columns to be used, because the names of each column must be identical with the name of the file attribute it represents.
- If the files to be processed contain some custom attributes you want to extract, you need to add their representative columns accordingly and ensure that these columns and these custom attributes are using identical names.

**Query type**

Select the type of the query you want `tMongoDBGridFSProperties` to perform to select the files from which you need to extract the attributes.

- **Filename**: you need to enter the name of the file to be used. This name is the value of the `filename` attribute of this file. Note that only one name is allowed.
  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.
- **Mongo Query**: enter the query to be used to select the files to be used.
  The example query, `{}` within double quotation marks provided with `tMongoDBGridFSProperties`, means to select all of the files in a bucket. You can put `{filename:{$regex:'REGEX_PATTERN'}}` to apply a regular expression to defining the file names to be used.

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
</table>
| No query timeout        | Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.  
  A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/). |

**Global Variables**

| Global Variables | NB_FILE: the number of files processed. This is an After variable and it returns an integer.  
  **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component combines MongoDB GridFS connection and data extraction and needs to use a Main link to connect to its following component in order to send data to this component.

Related scenario

For a scenario using tMongoDBGridFSProperties, see Managing files using MongoDB GridFS on page 2319.
tMongoDBGridFSPut

Connects to a MongoDB GridFS system to load files into it.
tMongoDBGridFSPut copies files from a local directory, pastes them into a given MongoDB GridFS system and if needs be, renames these files.

**tMongoDBGridFSPut Standard properties**

These properties are used to configure tMongoDBGridFSPut running in the Standard Job framework.
The Standard tMongoDBGridFSPut component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type                     | Either Built-In or Repository.  
|----------------------------------|--------------------------------|
|                                  | Built-In: No property data stored centrally.  
|                                  | Repository: Select the repository file where the properties are stored.  

| Use an existing connection       | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
|----------------------------------| Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.  

| Use replica set address or multiple query routers | Select this check box to show the Server addresses table.  
|---------------------------------------------------| In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.  

| Server and Port | IP address and listening port of the database server.  
|-----------------| Available when the Use replica set address check box is not selected.  
|                 | Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.  

| Database | Name of the database.  

| Use SSL connection | Select this check box to enable the SSL or TLS encrypted connection.  
|--------------------| Then you need to use the tSetKeystore component in the same Job to specify the encryption information.  
|                    | For further information about tSetKeystore, see tSetKeystore on page 3496.  

2317
Note that the SSL connection is available only for the version 2.4 + of MongoDB.

### Set read preference
Select this check box and from the **Read preference** drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

### Required authentication
Select this check box to enable the database authentication.

Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGOTIATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see **MongoDB Authentication** from the MongoDB documentation.

### Set Authentication database
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.

For further information about the MongoDB Authentication database, see **User Authentication database**.

### Username and Password
DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields.

### Bucket
Enter the name of the bucket you need to write files in. A bucket of GridFS is similar to a folder.

### Local Folder
Browse to, or enter the path to the folder in which the files to be copied and written to GridFS are stored.

### Use Perl5 Regex Expression as Filemask
Select this check box if you want to use Perl5 regular expressions in the **Files** field as file filters. This is useful when the name of the file to be used contains special characters such as parentheses.

For information about Perl5 regular expression syntax, see **Perl5 Regular Expression Syntax**.

### Files
In the **Files** area, the fields to be completed are:
Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the <code>cursor.close()</code> method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

Global Variables

| Global Variables | NB_FILE: the number of files processed. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/). |

Usage

| Usage rule | This component combines MongoDB GridFS connection and data extraction, thus usually used as a single-component subjob to copy data from a user-defined local directory to GridFS. It is often connected to the Job using OnSubjobOk or OnComponentOk link, depending on the context. |

Managing files using MongoDB GridFS

This scenario applies only to [Talend products with Big Data](https://docs.talend.com/).
In this scenario, the MongoDB GridFS components are used to create a Job to manage video files in MongoDB GridFS.

For further information about the GridFS system of MongoDB, see When to use GridFS.

For demonstration purposes, only one video file, called custom_hadoop.mp4, is used; you can use any of your own video files to replicate this scenario.

**Linking the components**

**Procedure**

1. In the Integration perspective of the Studio, create an empty Job, named FS_video for example, from the Job Designs node in the Repository tree view. For further information about how to create a Job, see Talend Studio User Guide.

2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are tMongoDBConnection, tMongoDBGridFS Put, tMongoDBGridFSList, tMongoDBGridFSProperties, tFilterColumns, tLogRow, tMongoDBGridFS Get and tMongoDBGridFSDelete.

3. Connect tMongoDBConnection to tMongoDBGridFSPut using the Trigger > On Subjob Ok link.

4. Repeat this operation to connect tMongoDBGridFSPut to tMongoDBGridFSList, tMongoDBGridFSList to tMongoDBGridFSPut, and then tMongoDBGridFSPut to tMongoDBGridFSDelete.

5. Connect tMongoDBGridFSList to tMongoDBGridFSProperties using the Row > Iterate link. This link allows tMongoDBGridFSList to send data to tMongoDBGridFSProperties iteratively.

6. Connect tMongoDBGridFSProperties to tFilterColumns using the Row > Main link.
7. Do the same to connect tFilterColumns to tLogRow.

**Connecting to MongoDB**

**Procedure**

1. Double-click tMongoDBConnection to open its Component view.

2. From the DB version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the authentication information required for the connection to MongoDB.

   If you use the host name of the MongoDB server, ensure that you have added the mapping between this host name and its IP address in the hosts file of the operating system in which the current Job is executed.

4. In the Database field, enter the name of the database hosting GridFS. This database is created on the fly if it dose not exist.

**Copying data to MongoDB GridFS**

**Procedure**

1. Double-click tMongoDBGridFSPut to open its Component view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket to be used to store files in GridFS. In this example, it is `talend_channel/61`.

4. In the **Local folder** field, enter the path, or browse to the folder where the files to be uploaded to GridFS are stored. As explained previously, it is a video file called `custom_hadoop.mp4`.

5. In the **Files** table, add one row by clicking the `[+ ]` button and in the **Filemask** column, enter `*.mp4` within the double quotation marks. This allows **tMongoDBGridFSPut** to copy all the files with the `.mp4` extension from the local folder you have specified to the bucket to be used in GridFS.

6. Leave the **New name** column empty, that is to say, leave the double quotation marks in this column as is, so as to keep the name of this video unchanged after being copied to GridFS.

**Listing files stored in MongoDB GridFS**

**Iterating on the files**

**Procedure**

1. Double-click **tMongoDBGridFSList** to open its **Component** view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be listed are stored. In this example, it is `talend_channel/61`.

4. In the **Query** field, enter the query to select the files you want tMongoDBGridFSList to iterate on to generate different file lists. In this example, leave the default one in order to iterate on all of the files stored in this `talend_channel/61` bucket.

   As explained previously, only one file, `custom_hadoop.mp4`, is expected.

### Extracting file metadata

#### Procedure

1. Double-click **tMongoDBGridFSProperties** to open its **Component** view.

2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.
3. In the **Bucket** field, enter the bucket in which the files to be used are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files about which you need to extract the metadata. In this example, select **Filename** to use the `filename` attribute of each GridFS file for query.

5. In the **Filename** field, press **Ctrl + Space** to display the variable list and choose the variable to be used. In this example, select `tMongoDBGridFSList.CURRENT_FILENAME` from the list. Then the expression to use the `CURRENT_FILENAME` variable is automatically added. This allows **tMongoDBGridFSProperties** to read each file name returned by **tMongoDBGridFSList**.

### Filtering attributes

**Procedure**

1. Double-click **tFilterColumns** to open its **Component** view.

2. Click the `[...]` button next to **Edit schema** to open the schema editor.

3. On the left side (the input side), select the column to be used and click the button to move this column to the right side (the output side). In this example, move every column to the right side except the `contentType` column.

   Each column represents a file attribute and the pre-defined schema of **tMongoDBGridFSProperties** automatically contains these columns.

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
Downloading files from MongoDB GridFS

Procedure

1. Double-click `tMongoDBGridFSGet` to open its Component view.

   ![Component view of tMongoDBGridFSGet](image)

   - Select the Use existing connection check box and from the Connection list, select the component in which the MongoDB connection to be used is defined.
   - In the Bucket field, enter the bucket in which the files to be retrieved are stored. In this example, it is `talend_channel/61`.
   - In the Local folder field, enter the path to the local folder in which you want to store the downloaded files. In this scenario, it is `C:/tmp/output`.
   - Select the Use Document ID as output filename check box to rename each downloaded file using the value of its ObjectID attribute. Since a file in GridFS is distinct by ID rather than by name, it is possible that several files are using the same file name. For this reason, when downloading this kind of files into the same directory without renaming them differently, an exception is returned to alert that the file being downloaded already exists. In order to avoid this error, you can either select the Overwrite local files check box to replace the existing one with the latest downloaded file or rename these files on the fly using their IDs. In this example, the strategy of renaming these files is adopted.

Remove files from MongoDB GridFS

Procedure

1. Double-click `tMongoDBGridFSDelete` to open its Component view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be deleted are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files to be deleted. In this example, select **Filename** to use the `filename` attribute of each GridFS file for query.

5. In the **Filename** field, enter the name of the file to be deleted.

### Executing the Job

**About this task**

Then you can run this Job.

The **tLogRow** component is used to present the execution result of the Job.

**Procedure**

1. If you want to configure the presentation mode on its **Component** view, double-click the **tLogRow** component to open the **Component** view and in the **Mode** area, then, select the **Table (print values in cells of a table)** radio box.
2. Press **F6** to run this Job.

**Results**

Once done, the **Run** view is opened automatically, where the metadata of the video `custom_hadoop.mp4` in GridFS is displayed.

```
Starting job FS_video at 15:00 06-04-2016.
[statistics] connecting to socket on port 3799
[statistics] connected
--------------[tLogRow_1]
<table>
<thead>
<tr>
<th>_id</th>
<th>filename</th>
<th>chunkSize</th>
<th>uploadBeta</th>
<th>length</th>
<th>md5</th>
</tr>
</thead>
</table>
| 57056663d6ef7432b24e2 | custom_hadoop.mp4 | 261120 | 2016-04-06 15:00:56 | 64449397 | d29ac54715ddd07e6f86b5ff18b5c7854

[statistics] disconnected
Job FS_video ended at 15:01 06-04-2016. (exit code=0)
```
The downloaded file can be found in the directory `C:/tmp/output`, using its ID as its file name.
tMongoDBInput

Retrieves records from a collection in the MongoDB database and transfers them to the following component for display or storage.

tMongoDBInput retrieves certain documents from a MongoDB database collection by supplying a query document containing the fields the desired documents should match.

**tMongoDBInput Standard properties**

These properties are used to configure tMongoDBInput running in the Standard Job framework.

The Standard tMongoDBInput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of the database versions.</td>
</tr>
<tr>
<td><strong>Use replica set address</strong></td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Server and Port</strong></td>
<td>IP address and listening port of the database server. Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Use SSL connection</strong></td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3496. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td><strong>Set read preference</strong></td>
<td>Select this check box and from the Read preference dropdown list that is displayed, select the member to which you need to direct the read operations.</td>
</tr>
</tbody>
</table>
If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB's documentation about Replication and its Read preferences.

**Required authentication**

Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOtiATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

**Set Authentication database**

If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database.

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

**Collection**

Name of the collection in the MongoDB database.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
If a column in the database is a JSON document and you need to read the entire document, put an asterisk (*) in the **DB column** column, without quotation marks around.

| **Query** | Specify the query condition. This field is available only when you have selected *Find query* from the **Query type** drop-down list.

For example, type in "\{id:4\}" to retrieve the record whose *id* is 4 from the collection specified in the **Collection** field.

**Note:**
Different from the query statements required in the MongoDB client software, the query here refers to the contents inside `find()`, such as the query here `\{id:4\}` versus the MongoDB client query `db.blog.find({id:4})`.

| **Aggregation stages** | Create a MongoDB aggregation pipeline by adding the stages you want the documents to pass through so as to obtain aggregated results from these documents. This table is available only when you have selected *Aggregation pipeline query* from the **Query type** drop-down list.

Only one stage is allowed per row in this **Aggregation stages** table and the stages are executed one by one in the order you place them in this table.

For example, if you want to aggregate documents about your customers using the `$match` and the `$group` stages, you need to add two rows to this **Aggregation stages** table and define the two stages as follows:

```
"{$match : {status : 'A'}}"
"{$group : { _id : '$cust_id', total : {$sum : '$amount'}}}"
```

In this aggregation, the customer documents with status *A* are selected; then among the selected customers, those using the same customer _id_ are grouped and the values from the *amount* fields of the same customer are summed up.

For a full list of the stages you can use and their related operators, see *Aggregation pipeline operators*.

For further information about MongoDB aggregation pipeline, see *Aggregation pipeline*.

| **Mapping** | Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows

```javascript
{
   
   _id: ObjectId("5099803df3f498bd2f98391"),
   person: { first: "Joe", last: "Walker" }
}
```

The *first* and the *last* fields have *person* as their parent node but the *_id* field does not have any parent node. So once completed, this **Mapping** table should read as follows:
### tMongoDBInput

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Sort by</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the column and choose the order for the sort operation. This field is available only when you have selected <strong>Find query</strong> from the <strong>Query type</strong> drop-down list.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Limit</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Type in the maximum number of records to be retrieved. This field is available only when you have selected <strong>Find query</strong> from the <strong>Query type</strong> drop-down list.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th><strong>tStatCatcher Statistics</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to collect the log data at the component level.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>No query timeout</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the <code>cursor.close()</code> method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Enable external sort</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Since the aggregation pipeline stages have a maximum memory use limit (100 megabytes) and a stage exceeding this limit will produce errors, when handling large datasets, select this check box to avoid aggregation stages exceeding this limit. For further information about this external sort, see <a href="https://docs.mongodb.org/manual/core/cursors/">Large sort operation with external sort</a>.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

| **A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.** |

| **To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.** |

| **2331** |
For further information about variables, see *Talend Studio User Guide*.

### Usage

#### Usage rule

As a start component, *tMongoDBInput* allows you to retrieve records from a collection in the MongoDB database and transfer them to the following component for display or storage.

### Retrieving data from a collection by advanced queries

This scenario applies only to *Talend products with Big Data*.

In this scenario, advanced MongoDB queries are used to retrieve the post by the author Anderson.

There are such posts in the collection *blog* of the MongoDB database *talend*:

```javascript
> db.blog.find()
{ "id" : ObjectId("5226d25e675f26b4a2876888"), "id" : 1, "post" : { "author" : "Andy", "title" : "Open Source Outlook", "keywords" : "Open Source,Talend", "contents" : "Talend, the leader of the open source world..." } }
{ "id" : ObjectId("5226d25e675f26b4a2876889"), "id" : 2, "post" : { "author" : "Andy", "title" : "Data Integration Overview", "keywords" : "Data Integration,Talend", "contents" : "Talend, the leading player in the BI field..." } }
{ "id" : ObjectId("5226d25e675f26b4a287688a"), "id" : 3, "post" : { "author" : "Anderson", "title" : "ELT Overview", "keywords" : "ELT,Talend", "contents" : "Talend, the big name in the ELT circle..." } }
{ "id" : ObjectId("5226d25e675f26b4a287688b"), "id" : 4, "post" : { "author" : "Andy", "title" : "Big Data Bang", "keywords" : "Big Data,Talend", "contents" : "Talend, the driving force for Big Data applications..." } }
>
```

To insert data into the database, see *Creating a collection and writing data to it* on page 2340.

### Linking the components

#### Procedure

1. Drop *tMongoDBConnection*, *tMongoDBClose*, *tMongoDBInput* and *tLogRow* onto the workspace.
2. Link *tMongoDBConnection* to *tMongoDBInput* using the *OnSubjobOk* trigger.
3. Link *tMongoDBInput* to *tMongoDBClose* using the *OnSubjobOk* trigger.
4. Link *tMongoDBInput* to *tLogRow* using a *Row > Main* connection.
Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.

4. In the Database field, enter the name of the MongoDB database.

5. Double-click tMongoDBInput to open its Basic settings view.
6. Select the **Use existing connection** option.

7. In the **Collection** field, enter the name of the collection, namely *blog*.

8. Click the [...] button next to **Edit schema** to open the schema editor.

9. Click the [+ ] button to add five columns, namely *id*, *author*, *title*, *keywords* and *contents*, with the type as **Integer** and **String** respectively.

10. Click **OK** to close the editor.

11. The columns now appear in the left part of the **Mapping** area.

12. For columns *author*, *title*, *keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.
13. In the **Query** box, enter the advanced query statement to retrieve the posts whose author is Anderson:

```
"{post.author : 'Anderson'}"
```

This statement requires that the sub-node of `post`, the node `author`, should have the value “Anderson”.

14. Double-click **tLogRow** to open its **Basic settings** view.

Select **Table (print values in cells of a table)** for a better display of the results.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

As shown above, the post by Anderson is retrieved.

### Related scenarios

For related scenarios, see:

- Creating a collection and writing data to it on page 2340
- Using MongoDB functions to create a collection and write data to it on page 2356
tMongoDBOutput

Executes the action defined on the collection in the MongoDB database.
tMongoDBOutput inserts, updates, upserts or deletes documents in a MongoDB database collection based on the incoming flow from the preceding component in the Job.

**tMongoDBOutput Standard properties**

These properties are used to configure tMongoDBOutput running in the Standard Job framework. The Standard tMongoDBOutput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of the database versions. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>IP address and listening port of the database server. Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3496. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td>Set write concern</td>
<td>Select this check box to set the level of acknowledgement requested from for write operations. Then you need to select the level of this operation.</td>
</tr>
</tbody>
</table>
Bulk write

Select this check box to insert, update or remove data in bulk. Note this feature is available only when the version of MongoDB you are using is 2.6+.

Then you need to select Ordered or Unordered to define how the MongoDB database processes the data sent by the Studio.

- If you select Ordered, MongoDB processes the queries sequentially.
- If you select Unordered, MongoDB optimizes the bulk write operations without keeping the order in which the individual operations were inserted in the bulk write.

In the Bulk write size field, enter the size of each query group to be processed by MongoDB. In the documentation of MongoDB, some restrictions and expected behaviors as to this size are explained. You can find the details on http://docs.mongodb.org/manual/core/bulk-write-operations/.

Required authentication

Select this check box to enable the database authentication.

Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

Set Authentication database

If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database.

Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

Collection

Name of the collection in the MongoDB database.

Drop collection if exist

Select this check box to drop the collection if it already exists.
<table>
<thead>
<tr>
<th><strong>Action on data</strong></th>
<th>The following operations are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>Insert</strong>: insert documents.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Set</strong>: modifies the existing fields of an existing document and appends a field if it does not exist in this document.</td>
<td></td>
</tr>
<tr>
<td>If you need to apply this action on all the documents in the collection to be used, select the <strong>Update all document</strong> check box that is displayed; otherwise, only the first document is updated.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update</strong>: replaces the existing documents with the incoming data but keeps the technical ID of these documents.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Upsert</strong>: inserts a document if it does not exist otherwise it applies the same rules as <strong>Update</strong>.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Upsert with set</strong>: inserts a document if it does not exist otherwise it applies the same rules as <strong>Set</strong>.</td>
<td></td>
</tr>
<tr>
<td>If you need to apply this action on all the documents in the collection to be used, select the <strong>Update all document</strong> check box that is displayed; otherwise, only the first document is updated.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Delete</strong>: delete documents.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No upon completion</strong> and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
<td></td>
</tr>
<tr>
<td>Click <strong>Sync columns</strong> to retrieve the schema from the previous component connected in the Job.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide.</em></th>
<th></th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide.</em></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
<td></td>
</tr>
<tr>
<td>You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
<td></td>
</tr>
</tbody>
</table>
### Mapping

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

The `first` and the `last` fields have `person` as their parent node but the `_id` field does not have any parent node. So once completed, this Mapping table should read as follows:

Not available when the **Generate JSON Document** check box is selected in **Advanced settings**.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Generate JSON Document

Select this check box for JSON configuration:

- **Configure JSON Tree**: click the [...] button to open the interface for JSON tree configuration. For more information, see Configuring a JSON Tree on page 4017.
- **Group by**: click the [+] button to add lines and choose the input columns for grouping the records.
- **Remove root node**: select this check box to remove the root node.
- **Data node** and **Query node** (available for update and upsert actions): type in the name of data node and query node configured on the JSON tree.

**Warning:**

These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

#### No query timeout

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see https://docs.mongodb.org/manual/core/cursors/.
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Usage

| Usage rule | tMongoDBOutput executes the action defined on the collection in the MongoDB database based on the flow incoming from the preceding component in the Job. |

Limitation

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• The “multi” parameter, which allows to update multiple documents at a time, is not supported. Therefore, if two documents have the same key, the first is always updated, but the second never will.</td>
</tr>
<tr>
<td>• For the update operation, the key cannot be a JSON array.</td>
</tr>
</tbody>
</table>

Creating a collection and writing data to it

This scenario applies only to Talend products with Big Data.
This scenario creates the collection blog and writes post data to it.

Linking the components

Procedure

1. Drop tMongoDBConnection, tFixedFlowInput, tMongoDBOutput, tMongoDBClose, tMongoDBInput and tLogRow onto the workspace.
2. Rename tFixedFlowInput as blog_post_data, tMongoDBOutput as write_data_to_collection, tMongoDBInput as read_data_from_collection and tLogRow as show_data_from_collection.
3. Link tMongoDBConnection to tFixedFlowInput using the OnSubjobOk trigger.
4. Link tFixedFlowInput to tMongoDBOutput using a Row > Main connection.
5. Link tFixedFlowInput to tMongoDBInput using the OnSubjobOk trigger.
7. Link tMongoDBInput to tLogRow using a Row > Main connection.

Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the connection details.
   In the Database field, enter the name of the MongoDB database.
4. Double-click tFixedFlowInput to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

```text
1;Andy;Open Source Outlook;Open Source,Talend,Talend, the leader of the open source world...
3;Andy;ELT Overview;ELT,Talend,Talend, the big name in the ELT circle...
2;Andy;Data Integration Overview;Data Integration,Talend,Talend, the leading player in the DI field...
```

5. Double-click **tMongoDBOutput** to open its **Basic settings** view.

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+] button to add five columns in the right part, namely *id, author, title, keywords* and *contents*, with the type as *Integer* and *String* respectively.

   Click to copy all the columns to the input table.

   Click Ok to close the editor.

8. The columns now appear in the left part of the Mapping area.

   For columns *author, title, keywords* and *contents*, enter their parent node *post*. By doing so, those nodes reside under the node *post* in the MongoDB collection.

9. Double-click **tMongoDBInput** to open its **Basic settings** view.
Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

10. Click the [..] button next to **Edit schema** to open the schema editor.

11. Click the [+] button to add five columns, namely *id*, *author*, *title*, *keywords* and *contents*, with the type as **Integer** and **String** respectively.

   Click **OK** to close the editor.

12. The columns now appear in the left part of the **Mapping** area.
For columns **author**, **title**, **keywords** and **contents**, enter their parent node **post** so that the data can be retrieved from the correct positions.

13. In the **Sort by** area, click the [+] button to add one line and enter **id** under **Column**. Select **asc** from the **Order asc or desc?** column to the right of the **id** column. This way, the retrieved records will appear in ascending order of the **id** column.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

```plaintext
[statistics] connecting to socket on port 3630
[statistics] connected

<table>
<thead>
<tr>
<th>id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source,Talend</td>
<td>Talend, the leader of the open source world...</td>
</tr>
<tr>
<td>2</td>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration,Talend</td>
<td>Talend, the leading player in the DI field...</td>
</tr>
<tr>
<td>3</td>
<td>Andy</td>
<td>ELT Overview</td>
<td>ELT,Talend</td>
<td>Talend, the big name in the ELT circle...</td>
</tr>
</tbody>
</table>

[statistics] disconnected
```

3. Switch to the database **talend** and read data from the collection **blog** in the MongoDB command line client. You can find that **author**, **title**, **keywords** and **contents** all reside under the node **post**. Meanwhile, the records are stored in the same order as the source input.

![MongoDB shell version: 2.2.0 connecting to: test > use talend > db.blog.find()](image)

### Upserting records in a collection

This scenario applies only to **Talend products with Big Data**.

This scenario upserts the collection **blog** as an existing record has its author changed and a new record is added. Before the upsert, the collection **blog** looks like:

```
1;Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
2;Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
3;Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...
```

Such records can be inserted to the database following the instructions of Creating a collection and writing data to it on page 2340.
Linking the components

Procedure

1. Drop `tMongoDBConnection`, `tFixedFlowInput`, `tMongoDBOutput`, `tMongoDBClose`, `tMongoDBInput` and `tLogRow` from the Palette onto the design workspace.
2. Rename `tFixedFlowInput` as `blog_post_data`, `tMongoDBOutput` as `write_data_to_collection`, `tMongoDBInput` as `read_data_from_collection` and `tLogRow` as `show_data_from_collection`.
3. Link `tMongoDBConnection` to `tFixedFlowInput` using the `OnSubjobOk` trigger.
4. Link `tFixedFlowInput` to `tMongoDBOutput` using a Row > Main connection.
5. Link `tFixedFlowInput` to `tMongoDBInput` using the `OnSubjobOk` trigger.
7. Link `tMongoDBInput` to `tLogRow` using a Row > Main connection.

Configuring the components

Procedure

1. Double-click `tMongoDBConnection` to open its Basic settings view.
   
   ![tMongoDBConnection_1](image)

   **Basic settings**
   
<table>
<thead>
<tr>
<th>Connection</th>
<th>DB Version</th>
<th>MongoDB 2.1.X</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server</td>
<td>&quot;localhost&quot;</td>
<td>Port 27017</td>
</tr>
<tr>
<td>Database</td>
<td>&quot;talend&quot;</td>
<td>Authentication</td>
</tr>
<tr>
<td></td>
<td></td>
<td>Required</td>
</tr>
</tbody>
</table>

2. From the DB Version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the connection details.
   In the Database field, enter the name of the MongoDB database.
4. Double-click `tFixedFlowInput` to open its Basic settings view.

2346
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data for upserting the MongoDB database, for example:

```
1;Andy;Open Source Outlook;Open Source,Talend,Talend, the leader of the open source world...
2;Andy;Data Integration Overview;Data Integration,Talend,Talend, the leading player in the DI field...
3;Anderson;ELT Overview;ELT,Talend,Talend, the big name in the ELT circle...
4;Andy;Big Data Bang;Big Data,Talend,Talend, the driving force for Big Data applications...
```

As shown above, the 3rd record has its author changed and the 4th record is new.

5. Double-click **tMongoDBOutput** to open its **Basic settings** view.

Select **Use existing connection** and **Die on error** check boxes.

In the **Collection** field, enter the name of the collection, namely *blog*.

Select **Upsert** from the **Action on data** list.

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+] button to add five columns in the right part, namely `id`, `author`, `title`, `keywords` and `contents`, with the type as `Integer` and `String` respectively.

   Click  to copy all the columns to the input table.
   Click Ok to close the editor.

8. In the Advanced Settings view, select the Generate JSON Document check box.
   Select the Remove root node check box.
   In the Data node and Query node fields, enter "data" and "query".

9. Click the [...] button next to Configure JSON Tree to open the configuration interface.
10. Right-click the node rootTag and select Add Sub-element from the contextual menu.
In the dialog box that appears, type in data for the Data node:

Click OK to close the window.
Repeat this operation to define query as the Query node.
Right-click the node data and select Set As Loop Element from the contextual menu.

**Warning:**
These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

11. Select all the columns under the Schema list and drop them to the data node.
In the window that appears, select Create as sub-element of target node.
Click OK to close the window.

Repeat this operation to drop the id column from the Schema list under the Query node.

12. Right-click the node id under data and select Add Attribute from the contextual menu.
In the dialog box that appears, type in type as the attribute name:

Click OK to close the window.

Right-click the node @type under id and select Set A Fix Value from the contextual menu.
In the dialog box that appears, type in integer as the attribute value, ensuring the id values are stored as integers in the database.

Click OK to close the window.

Repeat this operation to set this attribute for the id node under Query.

Click OK to close the JSON Tree configuration interface.

Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

Click the [...] button next to **Edit schema** to open the schema editor.

Click the [+ ] button to add five columns, namely *id, author, title, keywords* and *contents*, with the type as *Integer* and *String* respectively.

Click **OK** to close the editor.

The columns now appear in the left part of the **Mapping** area.

For columns *author, title, keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.

14. Double-click **tLogRow** to open its **Basic settings** view.
In the **Mode** area, select **Table (print values in cells of a table)** for better display.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

```plaintext
<table>
<thead>
<tr>
<th>Id</th>
<th>Author</th>
<th>Title</th>
<th>Keywords</th>
<th>Contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source, Talend</td>
<td>Talend, the leader of the open source world...</td>
</tr>
<tr>
<td>2</td>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration, Talend</td>
<td>Talend, the leading player in the BI field...</td>
</tr>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT, Talend</td>
<td>Talend, the big name in the ELT circle...</td>
</tr>
<tr>
<td>4</td>
<td>Andy</td>
<td>Big Data Blog</td>
<td>Big Data, Talend</td>
<td>Talend, the driving force for Big Data applications...</td>
</tr>
</tbody>
</table>
```

As shown above, the 3rd record has its author updated and the 4th record is inserted.
# tMongoDBRow

Executes the commands and functions of the MongoDB database.

## tMongoDBRow Standard properties

These properties are used to configure tMongoDBRow running in the Standard Job framework. The Standard tMongoDBRow component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of the database versions. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Use replica set address</strong></td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Server and Port</strong></td>
<td>Address and listening port of the database server. Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Use SSL connection</strong></td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. For further information about tSetKeystore, see tSetKeystore on page 3496. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td><strong>Required authentication</strong></td>
<td>Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
</tbody>
</table>
| Set Authentication database | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.  
For further information about the MongoDB Authentication database, see [User Authentication database](#). |
|-----------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Username and Password       | **DB user authentication data.**  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.  
Available when the **Required authentication** check box is selected.  
If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields. |
| Schema and Edit Schema       | **A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.**  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
| Execute command             | Select this check box to enter MongoDB commands in the **Command** field for execution.  
• **Command**: in this field, enter the command to be executed, if this command contains one single variable.  
  
  For example, if you need to construct the command  
  ```json  
  {"isMaster": 1}  
  ```  
  You need simply enter `isMaster` within quotation marks.  
• **Construct command from keys and values**: if the command to be executed contains multiple variables, select this check box and in the **Command keys and values** table, add the variables and their respective values to be used. |
For example, if you need to construct the following command:

```javascript
{ renameCollection : "<source_namespace>" , to : "<target_namespace>" ,
dropTarget : < true | false > }
```

You need to add three rows to the **Command keys and values** table and enter one variable-value pair to each row within quotation marks:

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>renameCollection</td>
<td>&quot;&lt;source_namespace&gt;&quot;</td>
</tr>
<tr>
<td>to</td>
<td>&quot;&lt;target_namespace&gt;&quot;</td>
</tr>
<tr>
<td>dropTarget</td>
<td>&lt; true</td>
</tr>
</tbody>
</table>

- **Construct command from a JSON string**: if you want to directly enter the command to be used, select this check box and enter this command in the **JSON string command** field that is displayed. Only one command is allowed per **tMongoDBRow**.

For example:

```json
"{createIndexes: 'restaurants',
indexes : [{key : {restaurant_id : 1}, name: 'id_index_2', unique: true}]}"
```

Note that you must use single quotation marks to surround the string values used in the command and double quotation marks to surround the command itself.

For further information about the MongoDB commands you can use in this field, see [https://docs.mongodb.org/manual/reference/command/](https://docs.mongodb.org/manual/reference/command/).

### Function

Enter MongoDB functions in the **Function** field for execution.

Not available when the **Execute command** check box is selected.

### Parameters value

Click the [+] button to add lines as needed and then define the parameter values in the form of variables or constant values, for example `row1.author` or 'Andy'. Note that the parameter values correspond to the parameters defined in the **Function** field, in the same order.

Not available when the **Execute command** check box is selected.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.
Global Variables

Global Variables

| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
| To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
| For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

| tMongoDBRow allows you to manipulate the MongoDB database through the MongoDB commands and functions.

Using MongoDB functions to create a collection and write data to it

This scenario applies only to Talend products with Big Data.

This scenario creates the collection blog and writes post data to it through the MongoDB functions.

Linking the components

Procedure

1. Drop tMongoDBConnection, tFixedFlowInput, tMongoDBRow, tMongoDBClose, tMongoDBInput and tLogRow onto the workspace.
2. Rename tFixedFlowInput as blog_post_data, tMongoDBRow as write_data_to_collection, tMongoDBInput as read_data_from_collection and tLogRow as show_data_from_collection.
3. Link tMongoDBConnection to tFixedFlowInput using the OnSubjobOk trigger.
4. Link tFixedFlowInput to tMongoDBRow using a Row > Main connection.
5. Link tFixedFlowInput to tMongoDBInput using the OnSubjobOk trigger.
7. Link tMongoDBInput to tLogRow using a Row > Main connection.
Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.
   In the Database field, enter the name of the MongoDB database.

4. Double-click tFixedFlowInput to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

- Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
- Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
- Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...

5. Double-click `tMongoDBRow` to open its **Basic settings** view.
Select the Use existing connection check box.

In the Function field, enter the MongoDB function to create the collection blog and insert data to it:

```javascript
"function (author, title, keywords, contents) {
  return db.blog.save(
    {author: author, title: title, keywords: keywords, contents: contents}
  );
}
```

6. Click the [...] button next to Edit schema to open the schema editor.
7. Click the [+] button to add four columns in the right part, namely author, title, keywords and contents, with the type of String.

Click to copy all the columns to the input table.
Click OK to close the editor.

8. In the Parameters value table, click the [+] button to add four lines and enter the values in sequence: row1.author, row1.title, row1.keywords and row1.contents. By doing so, data of row1 will be transferred to the parameters defined in the function.

Select the Use existing connection check box.
In the Collection field, enter the name of the collection, namely blog.

10. Click the [...] button next to Edit schema to open the schema editor.

11. Click the [+] button to add four columns, namely author, title, keywords and contents, with the type as String.
Click **OK** to close the editor.

12. Double-click **tLogRow** to open its **Basic settings** view.

![show_data_from_collection(tLogRow_1)](image)

In the **Mode** area, select **Table (print values in cells of a table)** for better display.

### Executing the Job

#### Procedure

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source, Talend</td>
<td>Talend, the leader of the open source world...</td>
</tr>
<tr>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration, Talend</td>
<td>Talend, the leading player in the DI field...</td>
</tr>
<tr>
<td>Andy</td>
<td>ETL Overview</td>
<td>ETL, Talend</td>
<td>Talend, the big name in the ETL circle...</td>
</tr>
</tbody>
</table>
**tMSAXInput (deprecated)**

Extracts data from a MicrosoftAX server based on a query.

**tMSAXInput Standard properties**

These properties are used to configure tMSAXInput running in the Standard Job framework.

The Standard tMSAXInput component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the Repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
</tbody>
</table>

**Version**

Select the type of the business connector to be used. The type may be:
- Dynamics AX 4.0
- Dynamics AX 2012

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>
## Usage

### Usage rule

This component is usually used as a start component. An output component is required.

<table>
<thead>
<tr>
<th>Note:</th>
<th>Dynamics AX 2012 type only.</th>
</tr>
</thead>
<tbody>
<tr>
<td>.NET Business Connector Assembly Path</td>
<td></td>
</tr>
<tr>
<td>Host</td>
<td></td>
</tr>
<tr>
<td>Port</td>
<td></td>
</tr>
<tr>
<td>AOS Server Instance</td>
<td></td>
</tr>
<tr>
<td>Domain</td>
<td></td>
</tr>
<tr>
<td>User and Password</td>
<td></td>

<tr>
<td>Company</td>
<td></td>
</tr>
<tr>
<td>Language</td>
<td></td>
</tr>
<tr>
<td>Configuration File</td>
<td></td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td></td>
</tr>
<tr>
<td>Table Name</td>
<td></td>
</tr>
<tr>
<td>Query</td>
<td></td>
</tr>
</tbody>
</table>

### Related scenarios

No scenario is available for the Standard version of this component yet.
tMSAXOutput (deprecated)

Writes data in a MicrosoftAX server.

**tMSAXOutput Standard properties**

These properties are used to configure tMSAXOutput running in the Standard Job framework.

The Standard tMSAXOutput component belongs to the Business family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the Repository file where properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>Version</td>
<td>Select the type of the business connector to be used. The type may be:</td>
</tr>
<tr>
<td></td>
<td>• Dynamics AX 4.0</td>
</tr>
<tr>
<td></td>
<td>• Dynamics AX 2012</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Inserting data in a defined table in a MicrosoftAX server

Warning:
Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.

This Java scenario describes a two-component Job that uses tMSAXOutput to insert four columns in a defined table in a MicrosoftAX server after it alters values in one of the inserted columns.

Setting up the Job

Procedure
1. Drop tFixedFlowInput and tMSAXOutput from the Palette to the design workspace.
2. Connect the two components together using a Row > Main connection.

Configuring tFixedFlowInput

Procedure
1. Double-click tFixedFlowInput to display its Basic settings view and define the component properties.

2. Set Schema type to Built-in and click the three-dot button next to Edit schema to display a dialog box where you can define the input schema.
3. Click the plus button and add the input schema columns, three in this example: name, city and street.
4. Click **OK** to close the dialog box and accept propagating the changes when prompted by the system.
   The three schema columns display automatically in the **Values** list.

5. Click in the **Value** column and enter a value for each of the input columns.

**Configuring tMSAXOutput**

**Procedure**

1. Double-click **tMSAXOutput** to open its **Basic settings** view and define the component properties.

   ![tMSAXOutput Basic Settings](image)

2. Set **Property type** to **Built-in**.

3. In the **Host** field, type in the IP address of the MicrosoftAX server and type in the domain name on which the MicrosoftAX server is hosted in the **Domain** field.

4. Enter your username and password for the server in the corresponding **fields** and enter the name of the table you want to write data in the **Table Name** field, **ADDRESS** in this example.

5. In the **Action on data** list, select the action you want to carry on, **Insert** in this example.

6. Click **Sync columns** to retrieve the schema from the preceding component.
   
   In this example, we want to retrieve the three input columns: **name**, **city** and **street** and write the data included in the three input columns in the MicrosoftAX server without any changes.
   
   If needed, click the three-dot button next to **Edit Schema** to verify the retrieved schema.

7. In the **Additional columns** list, click the plus button to add one line where you can define parameters for the new column to add to the row you want to write in the **ADDRESS** table.

8. Set a name, a data type, a position and a reference column in the corresponding columns for the line you added.
   
   In this example, we want to add a new column we call **"address"** after the **street** column.

9. Click in the **Local expression** column and press **Ctrl + space** on your keyboard to open the context variable list and select: `StringHandling.UPCASE(row2.city)+"-"+row2.street`. This expression will write the city name initially capped followed by the street name to form the address of **Bryant park**. Thus the address column in this example will contain the string: **New York-Midtown Manhattan**.
Job execution

Procedure
Save your Job and press F6 to execute it.

**tMSAXOutput** inserts in the **ADDRESS** table in the MicrosoftAX server a row that holds the three input columns, **name**, **city** and **street** in addition to the new **address** column that combines the city name and the street name.

Deleting data from a defined table in a MicrosoftAX server

**Warning:**
Before being able to use this component, make sure that you install and launch the MicrosoftAX server correctly.

This Java scenario describes a two-component Job that uses **tMSAXOutput** to delete from a defined table in a MicrosoftAX server all rows that do not match the data included in a key column.

In this example, the input schema we use is an **address** column that holds the following data: New York-Midtown Manhattan. We want to delete from the MicrosoftAX server all addresses that are not identical with this one.

Setting up the Job

**Procedure**
1. Drop **tFixedFlowInput** and **tMSAXOutput** from the Palette to the design workspace.
2. Connect the two components together using a **Row > Main** connection.

Configuring **tFixedFlowInput**

**Procedure**
1. Double-click **tFixedFlowInput** to display its **Basic settings** view and define the component properties.
2. Set **Schema type** to **Built-in** and click the three-dot button next to **Edit schema** to display a dialog box where you can define the input schema.
3. Click the plus button and add the input schema columns, *address* in this example.
4. Click **OK** to close the dialog box. The schema column displays automatically in the **Values** list.
5. Click in the **Value** column and enter a value for the input column.

### Setting up the connection to the MicrosoftAX server

**Procedure**

1. Double-click **tMSAXOutput** to open its **Basic settings** view and define the component properties.

2. Set **Property type** to **Built-in**.
3. In the **Host** field, type in the IP address of the MicrosoftAX server.
4. In the **Domain** field, type in the domain name on which the MicrosoftAX server is hosted.
5. Enter your username and password for the server in the corresponding fields.
6. In the **Table Name** field, enter the name of the table you want to delete data from, *ADDRESS* in this example.
Defining the action on data

Procedure

1. In the Action on data list, select the action you want to carry on, **Delete** in this example.
2. Click **Sync columns** to retrieve the schema from the preceding component. In this example, we want to retrieve the input column: **address**.
3. Click the three-dot button next to **Edit Schema** to open a dialog box where you can verify the retrieved schema.

![Schema dialog box](image)

4. In the output schema, select the **Key** check box next to the column name you want to define as a key column, and then click **OK** to validate your changes and close the dialog box.

**Note:**
When you select **Delete** as an action on data, you must always define the Reference column as a key column in order for **tMSAXOutput** to delete rows based on this key column.

5. In the **Additional columns** list, click the plus button to add one line and define the parameters the component will use as basis for the delete operation.

6. Set a name, an operator, a data type, a local expression, a position and a reference column in the corresponding columns for the line you added.

In this example, we want to delete from the **ADDRESS** table in the MicrosoftAX server all rows in which the address column is not equal to the address in the key **address** column and that reads as the following: **New York-Midtown Manhattan**.

**Note:**
When you select **Delete** as an action on data, you must always set **Position** to Replace. Otherwise, all settings in the **Additional columns** will not be taken into account when executing your Job.

Job execution

Procedure

Save your Job and press **F6** to execute it.

**tMSAXOutput** deletes from the **ADDRESS** table in the MicrosoftAX server all rows where the address string is not equal to the address in the key column.
tMsgBox

Opens a dialog box with an OK button requiring action from the user.
tMsgBox is a graphical break in the Job execution progress.

**tMsgBox Standard properties**

These properties are used to configure tMsgBox running in the Standard Job framework.
The Standard tMsgBox component belongs to the Misc family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Title</th>
<th>Text entered shows on the title bar of the dialog box created.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buttons</td>
<td>Listbox of buttons you want to include in the dialog box. The button combinations are restricted and cannot be changed. The <strong>Question</strong> button displays the <strong>Mask Answer</strong> check box. Select this check box if you want to mask the answer you type in the pop-up window that opens when you run the Job.</td>
</tr>
<tr>
<td>Icon</td>
<td>Icon shows on the title bar of the dialog box.</td>
</tr>
<tr>
<td>Message</td>
<td>Free text to display as message on the dialog box. Text can be dynamic (for example: retrieve and show a file name).</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | RESULT: the return value of the component. This is an After variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component can be used as intermediate step in a data flow or as a start or an end object in the Job flowchart. |
It can be connected to the next/previous component using either a **Row** or **Iterate** link.

| Limitation | n/a |

'Hello world!' type test

The following scenario creates a single-component Job, where `tMsgBox` is used to display the pid (process id) in place of the traditional “Hello World!” message.

**Setting up the Job**

**Procedure**

1. Drop a `tMsgBox` component from the Palette to the design workspace.
2. Define the dialog box display properties:

   ![Image of tMsgBox settings]

   - **Title**: "Talend Open Studio"
   - **Buttons**: OK (selected)
   - **Icon**: Information
   - **Message**: "Current date is: " + (`Talend Date.getCurrentDate()`) (between double quotation marks)

   ‘Title’ is the message box title, it can be any variable.

3. In the **Message** field, enter "Current date is: " between double quotation marks. Then click CTRL+Space to display the autocompletion list and select the following system routine, `Talend Date.getCurrentDate()`. Put brackets around this routine.

**Executing the Job**

**Procedure**

Switch to the Run tab to execute the Job defined.

**Results**

The Message box displays the message and requires the user to click **OK** to go to the next component or end the Job.

![Image of message box]

After the user clicked **OK**, the Run log is updated accordingly.
Related topic: see *Talend Studio User Guide.*
tMSSqlBulkExec

Offers gains in performance while executing the Insert operations to a Microsoft SQL Server database. The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

**tMSSqlBulkExec Standard properties**

These properties are used to configure tMSSqlBulkExec running in the Standard Job framework. The Standard tMSSqlBulkExec component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data is stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>JDBC Provider</td>
<td>Select the provider of the JDBC driver to be used, either <strong>Microsoft</strong> (recommended) or <strong>Open source JTDS</strong>.</td>
</tr>
<tr>
<td></td>
<td>When using this component with Datasource in Talend Runtime, you need to use the <strong>Open source JTDS</strong> driver.</td>
</tr>
<tr>
<td></td>
<td>Note that when <strong>Microsoft</strong> is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Remote File Name

Name of the file to be loaded.

**Warning:**
This file is located on the machine specified by the URI in the Host field so it should be on the same machine as the database server.

### Advanced settings

**Action**

Select the action to be carried out.

**Bulk insert**, **Bulk update** and **Bcp query out**, depending on the action selected, the required information varies.

**Additional JDBC parameters**

Specify additional JDBC parameters for the database connection being created.

This property is not available when the **Use an existing connection** check box in the **Basic settings** view is selected.

**Fields terminated by**

Character, string or regular expression to separate fields.

**Rows terminated**

String (ex: "\n" on Unix) to distinguish rows.

**First row**

Type in the number of the row where the action should start.

**Code page**

OEM code pages used to map a specific set of characters to numerical code point values.

**Data file type**

Select the type of data being handled.
**Output**

Select the type for the standard output of the Microsoft SQL Server database:

- to console
- to global variable

This property is available when BCP query out is selected from the Action drop-down list.

**Fire Triggers**

Select this check box to execute any insert trigger defined on the table into which data will be loaded during the bulk insert operation.

This property is available when Bulk insert is selected from the Action drop-down list.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Enable parallel execution**

Select this check box to perform high-speed data processing, by treating multiple data flows simultaneously. Note that this feature depends on the database or the application ability to handle multiple inserts in parallel as well as the number of CPU affected. In the Number of parallel executions field, either:

- Enter the number of parallel executions desired.
- Press Ctrl + Space and select the appropriate context variable from the list. For further information, see Talend Studio User Guide.

Note that when parallel execution is enabled, it is not possible to use global variables to retrieve return values in a subjob.

- The Action on table field is not available with the parallelization function. Therefore, you must use a tCreateTable component if you want to create a table.
- When parallel execution is enabled, it is not possible to use global variables to retrieve return values in a subjob.

**Usage**

**Usage rule**

This component is to be used along with tMSSqlBulkExec component. Used together, they can offer gains in performance while feeding a MSSql database.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic
connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

For use cases in relation with **tMSSqlBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
tMSSqlClose

Closes a transaction in the MSSql databases.

**tMSSqlClose Standard properties**

These properties are used to configure tMSSqlClose running in the Standard Job framework.

The Standard tMSSqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</thead>
</table>
| Dynamic settings | Click the `[+]` button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic |
Related scenario

For `tMSSqlColumnList` related scenario, see Iterating on a DB table and listing its column names on page 2445.
tMSSqlCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tMSSqlCommit validates the data processed through the job into the connected DB.

tMSSqlCommit Standard properties

These properties are used to configure tMSSqlCommit running in the Standard Job framework.
The Standard tMSSqlCommit component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Warning:

If you want to use a Row > Main connection to link tMSSqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

Advanced settings

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

Usage

| Usage rule | This component is more commonly used with other tMSSql* components, especially with the tMSSqlConnection and tMSSqlRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in
different databases, especially when you are working in an
environment where you cannot change your Job settings, for
example, when your Job has to be deployed and executed
independent of Talend Studio.

Once a dynamic parameter is defined, the Component List
box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading
data from databases through context-based dynamic
connections on page 2472 and Reading data from different
MySQL databases using dynamically loaded connection
parameters on page 495. For more information on Dynamic
settings and context variables, see Talend Studio User
Guide.

Related scenarios

For a tMSSqlCommit related scenario, see Inserting data in mother/daughter tables on page 2452.
tMSSqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tMSSqlConnection opens a connection to a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlConnection Standard properties**

These properties are used to configure tMSSqlConnection running in the Standard Job framework.
The Standard tMSSqlConnection component belongs to the Databases and the ELT families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>

</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true,trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the `tRunJob` component. Using a shared connection together with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration.

This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not visible when the **Use or register a shared DB Connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.
Share identity insert in multi table

Select this check box to share `IDENTITY_INSERT` among multiple Microsoft SQL tables that accept data through the same database connection.

This option prevents errors caused by setting `IDENTITY_INSERT` to ON (or OFF) repeatedly when writing Microsoft SQL tables through a database connection. It is necessary to check this option when the component is used along with multiple `tMSSqlOutput` components with their Turn on Identity insert options checked in the Basic settings tab.

Note that checking this option may decrease the execution performance.

TStatCatcher Statistics

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

Usage

Usage rule

This component is more commonly used with other `tMSSql*` components, especially with the `tMSSqlCommit` and `tMSSqlRollback` components.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Inserting data into a database table and extracting useful information from it

The scenario describes a Job that reads the employee data from a text file, inserts the data into a table of an MSSQL database, then extracts useful data from the table, and displays the information on the console.
This scenario involves the following components:

- **tMSSqlConnection**: establishes a connection to the MSSQL server.
- **tFileInputDelimited**: reads the input file, defines the data structure and sends it to the next component.
- **tMSSqlOutput**: writes data it receives from the preceding component into a table of an MSSQL database.
- **tMSSqlInput**: extracts data from the table based on an SQL query.
- **tLogRow**: displays the information it receives from the preceding component on the console.
- **tMSSqlCommit**: commits the transaction in the connected MSSQL server.

### Setting up the Job

**Procedure**

1. Drop the following components from the Palette onto the design workspace: tMSSqlConnection, tFileInputDelimited, tMSSqlOutput, tMSSqlInput, tLogRow, and tMSSqlCommit.
2. Connect tMSSqlConnection to tFileInputDelimited using a Trigger > OnSubjobOk link.
3. Do the same to connect tFileInputDelimited to tMSSqlInput and tMSSqlInput to tMSSqlCommit.
4. Connect tFileInputDelimited to tMSSqlOutput using a Row > Main link.
5. Do the same to connect tMSSqlInput to tLogRow.
Configuring the components

Opening a connection to the MSSQL server

**Procedure**

1. Double-click the tMSSqlConnection component to open its Basic settings view in the Component tab.

![tMSSqlConnection_1](image_url)

2. In the Host field, type in the IP address or hostname of the MSSQL server, 192.168.30.47 in this example.
3. In the Port field, type in the port number of the database server, 1433 in this example.
4. In the Schema field, type in the schema name, dbo in this example.
5. In the Database field, type in the database name, talend in this example.
6. In the Username and Password fields, enter the credentials for the MSSQL connection.

Reading the input data

**Procedure**

1. Double-click the tFileInputDelimited component to open its Component view.

![tFileInputDelimited_1](image_url)

2. Click the [...] button next to the File Name/Stream field to browse to the input file. In this example, it is D:/Input/Employee_Wage.txt. This text file holds three columns: id, name and wage.

id;name;wage 51;Harry;2300 40;Ronald;3796 17;Theodore;2174 21;James;19
3. In the **Header** field, type in 1 to skip the first row of the input file.

4. Click **Edit schema** to define the data to pass on to the **tMSSqlOutput** component. In this example, we define *id* as the key, and specify the length and precision for each column respectively. Click **OK** to close the schema editor. A dialog box opens, and you can choose to propagate the schema to the next component.

![Schema of tFileInputDelimited_1](image)

Related topic: **tFileInputDelimited** on page 1019.

**Writing the data into the database table**

**Procedure**

1. Double-click the **tMSSqlOutput** component to open its **Basic settings** view in the **Component** tab.

2. Type in required information for the connection or use the existing connection you have configured before. In this example, we select the **Use an existing connection** check box. If multiple connections are available, select the connection you want to use from the **Component List** drop-down list.

3. In the **Table** field, type in the name of the table you want to write the data to: *Wage_Info* in this example. You can also click the [...] button next to the **Table** field to open a dialog box and select a proper table.

4. Select **Create table if not exists** from the **Action on table** drop-down list.

5. Select **Insert if not exists** from the **Action on data** drop-down list.

6. Click **Sync columns** to retrieve the schema from the preceding component.
Extracting useful information from the table

Procedure

1. Double-click the **tMSSqlInput** component to open its **Basic settings** view in the **Component** tab.

   ![tMSSqlInput component](image)

   - **Use an existing connection**: Select the use an existing connection check box. If multiple connections are available, select the connection you want to use from the **Component List** drop-down list.
   - **Table Name**: Click **Edit schema** to define the data structure to be read from the table. In this example, we need to read all three columns from the table.
   - **Table Name**: Type in the name of the table you want to read the data from: **Wage_Info** in this example.
   - **Query**: In the **Query** field, fill in the SQL query to be executed on the table specified. To obtain the data of employees whose wages are above the average value and order them by id, enter the SQL query:
     ```sql
     SELECT * FROM Wage_Info
     WHERE wage > (SELECT avg(wage) FROM Wage_Info)
     ORDER BY id
     ```

2. Select the **Use an existing connection** check box. If multiple connections are available, select the connection you want to use from the **Component List** drop-down list.

3. Click **Edit schema** to define the data structure to be read from the table. In this example, we need to read all three columns from the table.

4. In the **Table Name** field, type in the name of the table you want to read the data from: **Wage_Info** in this example.

5. In the **Query** field, fill in the SQL query to be executed on the table specified. To obtain the data of employees whose wages are above the average value and order them by id, enter the SQL query.
query as follows: SELECT * FROM Wage_Info WHERE wage > (SELECT avg(wage) FROM Wage_Info) ORDER BY id

Displaying information on the console

Procedure

1. Double-click the tLogRow component to open its Basic settings view.
2. In the Mode area, select Table (print values in cells of a table).

Committing the transaction and closing the connection

Procedure

1. Double-click the tMSSqlCommit component to open its Basic settings view.
2. Select the Close Connection check box.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.

The information of employees whose wages are above the average value ordered by id is displayed on the console.
tMSSqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition.
tMSSqlInput reads data and extracts fields based on a query from a Microsoft SQL Server database or a Microsoft Azure SQL database. Then it passes on the field list to the next component via a Main row link.

**tMSSqlInput Standard properties**

These properties are used to configure tMSSqlInput running in the Standard Job framework.
The Standard tMSSqlInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Database icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>JDBC Provider</td>
<td>Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.</td>
</tr>
<tr>
<td></td>
<td>When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.</td>
</tr>
<tr>
<td></td>
<td>Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
**Query type and Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration.

This option works only when you deploy and run your Job in Talend Runtime. This check box is not available when the Use an existing connection check box is selected.

**Data source alias**

Enter the alias of the data source created on the Talend Runtime side.

This field is available only when the Specify a data source alias check box is selected.

### Advanced settings

**Additional JDBC parameters**

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair.

For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the Use an existing connection check box is selected.

**Trim all the String/Char columns**

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**

Remove leading and trailing whitespace from defined columns.

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
Usage

Usage rule | This component covers all possible SQL queries for MS SQL server databases.

Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related topics, see:

- tMSSqlConnection on page 2386

For related topic in tContextLoad, see Reading data from different MySQL databases using dynamically loaded connection parameters on page 495.
tMSSqlLastInsertId

Retrieves the last primary keys added by a user to a MSSql table.

`tMSSqlLastInsertId` displays the last IDs added to a table from a MSSql specified connection.

**tMSSqlLastInsertId Standard properties**

These properties are used to configure `tMSSqlLastInsertId` running in the Standard Job framework.
The Standard `tMSSqlLastInsertId` component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <code>line</code> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

| Component list | Select the **tMSSqlConnection** component on the **Component list** to reuse the connection details you already defined, if there are more than one component in this list. |
### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
Related scenario

For a related scenario, see Getting the ID for the last inserted record with tMysqlLastInsertId on page 2481
**tMSSqlOutput**

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

`tMSSqlOutput` writes, updates, makes changes or suppresses entries in a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlOutput Standard properties**

These properties are used to configure `tMSSqlOutput` running in the Standard Job framework.

The Standard `tMSSqlOutput` component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

### JDBC Provider
Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.

When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.

Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations: Default: No operation is carried out. Drop and create table: The table is removed and created again. Create table: The table does not exist and gets created. Create table if not exists: The table is created if it does not exist. Drop table if exists and create: The table is removed if it already exists and created again. Clear table: The table content is deleted.</td>
</tr>
</tbody>
</table>
### Truncate table
The table content is deleted. You do not have the possibility to rollback the operation.

### Turn on identity insert
Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).

### Action on data
On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Single Insert Query**: Add entries to the table in a batch
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
- **Delete**: Remove entries corresponding to the input flow.
- **Insert if not exist**: Add new entries to the table if they do not exist.

**Warning:**

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

### Specify identity field
Select this check box to specify the identity field, which is made up of an automatically incrementing identification number.

When this check box is selected, three other fields are displayed:

- **Identity field**: select the column you want to define as the identity field from the list.
- **Start value**: type in a start value, used for the very first row loaded into the table.
- **Step**: type in an incremental value, added to the value of the previous row that was loaded.

This check box is available only when you select Drop and create table, Create table, Create table if not exists, or Drop table if exists and create from the Action on table list, and will disappear if you select the Enable parallel execution check box in the Advanced settings view. If you select this check box with the Turn on identity insert check box cleared and the Create table if not exists option selected from the Action on table list and if the specified table does not exist, only a table will be created without inserting data into it.
### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

#### Built-In

**Built-In**: You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://help.talend.com).

#### Repository

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://help.talend.com).

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not available when the **Use an existing connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.
### Advanced settings

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</th>
</tr>
</thead>
</table>

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

#### Commit every

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

#### Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type in the name of the schema column to be altered or inserted as new column</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL expression</td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td>Position</td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td>Reference column</td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
</tbody>
</table>

#### Use field options

Select this check box to customize a request, especially when there is double action on data.

#### Ignore date validation

Select this check box to ignore the date validation and insert the data directly into the database for the data types of DATE, DATETIME, DATETIME2 and DATETIMEOFFSET.

#### Enable debug mode

Select this check box to display each step during processing entries in a database.

#### Support null in "SQL WHERE" statement

Select this check box if you want to deal with the Null values contained in a DB table.

**Note:**

Make sure that the **Nullable** check box is selected for the corresponding columns in the schema.
### Use Batch
Select this check box to activate the batch mode for data processing.
This check box is available only when you have selected the **Insert**, the **Update**, the **Single Insert Query** or the **Delete** option in the **Action on data** list.

**Note:**
If you select the **Single Insert Query** option in the **Action on data** list, be aware that the batch size must be lower than or equal to the limit of parameter markers authorized by the JDBC driver (generally 2000) divided by the number of columns. For more information, see **Limitation** below.

### Batch Size
Specify the number of records to be processed in each batch.
This field appears only when the **Use batch mode** check box is selected.

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_UPDATED</td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_INSERTED</td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_DELETED</td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_LINE_REJECTED</td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.
## Usage

### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MSSql database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error.

For an example of tMysqlOutput in use, see Retrieving data in error with a Reject link on page 2500.

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Limitation

When the Single Insert Query option is selected in the Action on data list, an SQL Prepared Statement is generated, for example, INSERT INTO table (col1, col2, col3) VALUES (?,?,?,?) , (?,?,?,?) , (?,?,?,?) , (?,?,?,?) . Within brackets are the groups of parameters the number of which cannot exceed 2000, generally, depending on the JBDC driver. Therefore, the batch size should be set so that this limit is respected.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

## Related scenarios

For tMSSqlOutput related topics, see:

- tMSSqlConnection on page 2386.
- Inserting a column and altering data using tMysqlOutput on page 2492.
tMSSqlOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the MSSql database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

tMSSqlOutputBulk writes a file with columns based on the defined delimiter and the MSSql standards.

**tMSSqlOutputBulk Standard properties**

These properties are used to configure tMSSqlOutputBulk running in the Standard Job framework.

The Standard tMSSqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning:</strong> This file is generated on the local machine or a shared folder on the LAN.</td>
<td></td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows at the end of the records.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row separator</td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td>Include header</td>
<td>Select this check to include the column header.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select the encoding from the list or select Custom and define it manually.</td>
</tr>
<tr>
<td></td>
<td>This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td>tStaCatcher statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see *Talend Studio User Guide*.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with <em>tMSSqlBulkExec</em> component. Used together they offer gains in performance while feeding a MSSql database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/MS SQL Server</td>
</tr>
</tbody>
</table>

**Related scenarios**

For use cases in relation with *tMSSqlOutputBulk*, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
tMSSqlOutputBulkExec

Gains in performance during Insert operations to a Microsoft SQL Server database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component.

tMSSqlOutputBulkExec Standard properties

These properties are used to configure tMSSqlOutputBulkExec running in the Standard Job framework. The Standard tMSSqlOutputBulkExec component belongs to the Databases family. The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>Select the action to be carried out</td>
</tr>
<tr>
<td></td>
<td>Bulk insert   Bulk update</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository .</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

---

### JDBC Provider
Select the provider of the JDBC driver to be used, either **Microsoft** (recommended) or **Open source JTDS**.

When using this component with Datasource in Talend Runtime, you need to use the **Open source JTDS** driver.

Note that when **Microsoft** is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to `mssql-jdbc.jar` and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

### Host
Database server IP address.

Currently, only `localhost`, `127.0.0.1` or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using `tMSSqlOutputBulkExec` is deployed.

### Port
Listening port number of DB server.

### DB name
Name of the database.

### Schema
Name of the schema.

### Username and Password
DB user authentication data.

To enter the password, click the `[...]` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Table
Name of the table to be written.

Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

### Action on table
On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
<table>
<thead>
<tr>
<th><strong>Create a table if not exists</strong>: The table is created if it does not exist.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>Clear a table</strong>: The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Schema and Edit schema</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

- When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. |
- You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |

<table>
<thead>
<tr>
<th><strong>Click</strong> <strong>Edit schema</strong> <strong>to make changes to the schema.</strong> If the current schema is of the <strong>Repository</strong> type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>File Name</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Name of the file to be generated and loaded.</td>
</tr>
</tbody>
</table>

**Warning:** This file is generated on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server. |

<table>
<thead>
<tr>
<th><strong>Append</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to add the new rows at the end of the records.</td>
</tr>
</tbody>
</table>

**Advanced settings** |

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair.</td>
</tr>
</tbody>
</table>
For example, `encrypt=true;trustServerCertificate=false; hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection. This field is not available if the **Use an existing connection** check box is selected.

<table>
<thead>
<tr>
<th>Field separator</th>
<th>Character, string or regular expression to separate fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Row separator</td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</td>
</tr>
<tr>
<td>First row</td>
<td>Type in the number of the row where the action should start.</td>
</tr>
<tr>
<td>Include header</td>
<td>Select this check box to include the column header.</td>

Related scenarios

For use cases in relation with `tMSSqlOutputBulkExec`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508
- Inserting data in bulk in MySQL database on page 2515
tMSSqlRollback

Cancels the transaction commit in the MSSql database and thus avoids to commit part of a transaction involuntarily.

**tMSSqlRollback Standard properties**

These properties are used to configure tMSSqlRollback running in the Standard Job framework.
The Standard tMSSqlRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

| Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608. |

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tMSSql* components, especially with the tMSSqlConnection and tMSSqlCommit components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
| Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
| For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection |
Related scenario

For `tMSSqlRollback` related scenario, see Rollback from inserting data in mother/daughter tables on page 2455.
tMSSqlRow

Acts on the actual DB structure or on the data (although without handling data).

tMSSqlRow executes the SQL query stated onto the specified Microsoft SQL Server or Azure SQL database, depending on the nature of the query and the database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tMSSqlRow Standard properties**

These properties are used to configure tMSSqlRow running in the Standard Job framework.

The Standard tMSSqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

### Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

| JDBC Provider | Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS. |

2418
When using this component with Datasource in Talend Runtime, you need to use the **Open source JTDS** driver.

Note that when *Microsoft* is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to `mssql-jdbc.jar` and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>

<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Click Edit schema</strong></td>
<td>to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td>• <strong>View schema</strong>:</td>
<td>choose this option to view the schema only.</td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>:</td>
<td>choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>:</td>
<td>choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
<tr>
<td><strong>Table name</strong></td>
<td>Name of the table to be used.</td>
</tr>
<tr>
<td><strong>Turn on identity insert</strong></td>
<td>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</td>
</tr>
<tr>
<td><strong>Query type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> Fill in manually the query statement or build it graphically using SQLBuilder</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
<td></td>
</tr>
<tr>
<td><strong>Guess Query</strong></td>
<td></td>
</tr>
<tr>
<td>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the <strong>Query</strong> field.</td>
<td></td>
</tr>
<tr>
<td><strong>Query</strong></td>
<td></td>
</tr>
<tr>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
<td></td>
</tr>
<tr>
<td><strong>Specify a data source alias</strong></td>
<td></td>
</tr>
</tbody>
</table>
| Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*.  
This check box is not available when the **Use an existing connection** check box is selected. |
| **Data source alias** |
| Enter the alias of the data source created on the *Talend Runtime* side.  
This field is available only when the **Specify a data source alias** check box is selected. |
| **Die on error** |
| This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link. |

**Advanced settings**

| **Additional JDBC parameters** |
| Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30; for Azure SQL database connection.  
This field is not available if the **Use an existing connection** check box is selected. |
| **Propagate QUERY's recordset** |
| Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.  
**Note:**  
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY's recordset should be set to the type of *Object* and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement** |
| Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by "?" in
the SQL instruction of the **Query** field in the **Basic Settings** tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.

**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

**Note**: This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
<tr>
<td></td>
<td>The <strong>Dynamic settings</strong> table is available only when the <strong>Use an existing connection</strong> check box is selected in the <strong>Basic</strong> tab.</td>
</tr>
</tbody>
</table>
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related topics, see:

- Combining two flows for selective output on page 2529
- Procedure on page 635.
- Removing and regenerating a MySQL table index on page 2523.
tMSSqlSCD

Tracks and reflects changes in a dedicated SCD table in a Microsoft SQL Server or Azure SQL database. tMSSqlSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tMSSqlSCD Standard properties**

These properties are used to configure tMSSqlSCD running in the Standard Job framework. The Standard tMSSqlSCD component belongs to the Business Intelligence and the Databases families. The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>

</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

<table>
<thead>
<tr>
<th>JDBC Provider</th>
<th>Select the provider of the JDBC driver to be used, either <strong>Microsoft</strong> (recommended) or <strong>Open source JTDS</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When using this component with Datasource in Talend Runtime, you need to use the <strong>Open source JTDS</strong> driver.</td>
</tr>
</tbody>
</table>
Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

<table>
<thead>
<tr>

</tr>
<tr>
<td>Use memory saving Mode</td>
<td>Select this check box to maximize system performance.</td>
</tr>
</tbody>
</table>
### Source keys include Null

Select this check box to allow the source key columns to have Null values.

**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

#### End date time details

Specify the time value of the SCD end date time setting in the format of `HH:mm:ss`. The default value for this field is `12:00:00`.

This field appears only when SCD **Type 2** is used and **Fixed year value** is selected for creating the SCD end date.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

#### Debug mode

Select this check box to display each step during processing entries in a database.

### Global Variables

#### Global Variables

- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>

#### Dynamic settings

Click the [+] button to add a row in the table and fill the `Code` field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The *Dynamic settings* table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on *Dynamic settings* and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>This component does not support using SCD type 0 together with other SCD types.</th>
</tr>
</thead>
</table>

### Related scenario

For related topics, see *tMysqlSCD* on page 2534.
**tMSSqlSP**

Offers a convenient way to centralize multiple or complex queries in a database and calls them easily. tMSSqlSP calls the stored procedure in a Microsoft SQL Server or Azure SQL database.

**tMSSqlSP Standard properties**

These properties are used to configure tMSSqlSP running in the Standard Job framework.

The Standard tMSSqlSP component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>JDBC Provider</th>
<th>Select the provider of the JDBC driver to be used, either <strong>Microsoft</strong> (recommended) or <strong>Open source JTDS</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>When using this component with Datasource in Talend Runtime, you need to use the <strong>Open source JTDS</strong> driver.</td>
<td></td>
</tr>
</tbody>
</table>
Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>In SP principle, the schema is an input parameter.</td>
</tr>
<tr>
<td></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>SP Name</td>
<td>Type in the exact name of the Stored Procedure</td>
</tr>
<tr>
<td>Is Function / Return result in</td>
<td>Select this check box, if only a value is to be returned. Select on the list the schema column, the value to be returned is based on.</td>
</tr>
<tr>
<td>Parameters</td>
<td>Click the Plus button and select the various Schema Columns that will be required by the procedures. Note</td>
</tr>
</tbody>
</table>
that the SP schema can hold more columns than there are parameters used in the procedure.

Select the Type of parameter:

**IN**: Input parameter

**OUT**: Output parameter/return value

**IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).

**RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**
Check Inserting data in mother/daughter tables on page 2452, if you want to analyze a set of records from a database table or DB query and return single records.

---

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration.

This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not available when the **Use an existing connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

---

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair.

For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate="*.database.windows.net";loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

---

### Usage

#### Usage rule

This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.

#### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for
example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Limitation

The Stored Procedures syntax should match the Database syntax.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Retrieving personal information using a stored procedure

This scenario describes a Job that retrieves a personal information record from a specified table using a stored procedure according to the *id* value defined in the input flow.

In this scenario, the table to retrieve data from contains the personal information. To reproduce this scenario, you can write the data into the table from a CSV file like the following. For how to write data into a MS SQL table, see Inserting data into a database table and extracting useful information from it on page 2388.

```
id;name;sex;age
1;Ford;Male;25
2;Rose;Female;30
3;Sabrina;Female;28
4;Teddy;Male;32
5;Kate;Male;35
```
In this scenario, the stored procedure used to retrieve the personal information is as follows:

```sql
CREATE PROCEDURE [dbo].[QueryPerson]
@id int,
@name varchar(50)
AS
BEGIN
SET NOCOUNT ON
SELECT * FROM dbo.person where id=@id
END
```

Dropping and linking the components

Procedure

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tFixedFlowInput component, a tMSSqlSP component, a tParseRecordSet component, and two tLogRow components.
2. Connect tFixedFlowInput to tMSSqlSP using a Row > Main link.
3. Do the same to connect tMSSqlSP to the first tLogRow, the first tLogRow to tParseRecordSet, and tParseRecordSet to the second tLogRow.

Configuring the components

Configuring the input component

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.

2. Click the [...] button next to Edit schema to open the schema editor.
Click the [+] button to add two columns: *id* of the integer type and *name* of the string type. Click OK to close the schema editor.

3. In the **Mode** area, fill each column with respective value. In this example, the *id* value is set to 4, and the *name* value is null since it is not used in the select SQL statement in the stored procedure.

**Configuring the tMSSqlSP component**

**Procedure**

1. Double-click **tMSSqlSP** to open its **Basic settings** view.

2. Fill in the **Host**, **Port**, **Schema**, **Database**, **Username**, and **Password** fields with your MS SQL Server connection details.

3. In the **SP Name** field, enter the name of the stored procedure to be used. In this example, it is **QueryPerson**.
4. Click the [...] button next to Edit schema to open the schema editor.

![Schema editor]

Click the button to copy all columns from the input schema to the output schema, and then click the [+] button in the right panel to add a new column person of the object type to hold the personal information to be retrieved from the database.

Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. In the Parameters area, click the [+] button to add three rows and select a schema column and its type for each row. In this example, the id and name columns are of type IN, and the person column is of type RECORD SET.

**Configuring the tParseRecordSet component**

**Procedure**

1. Double-click tParseRecordSet to open its Basic settings view.

![tParseRecordSet settings]

2. From the Prev. Comp. Column list drop-down list, select the column that holds the personal information to be parsed. In this example, it is person.

3. Click the [...] button next to Edit schema to open the schema editor.
Click the [+] button in the right panel to add four columns: *id* and *age* of the integer type, and *name* and *sex* of the string type. Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

4. In the **Attribute table** area, fill in each **Value** column with the corresponding column name in the MS SQL Server table that holds the personal information.

**Configuring the output components**

**Procedure**

1. Double-click the first **tLogRow** to open its **Basic settings** view.

   ![tLogRow configuration](image)

   In the **Mode** area, select **Vertical (each row is a key/value list)** for a better display of the result.

2. Do the same to configure the second **tLogRow**.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.
The personal information with the id of 4 in the MS SQL table is displayed in the lower table on the console. Note that the values of the id and name columns shown in the upper table are the input data.

### Related scenarios

For related scenarios, see:

- Using tMysqlSP to find a State Label using a stored procedure on page 2554.
- Checking number format using a stored procedure on page 2771.
- Executing a stored procedure using tMDMSP on page 2174.

Check as well Inserting data in mother/daughter tables on page 2452 to analyze a set of records from a database table or DB query and return single records.
**tMSSqlTableList**

Lists the names of a given set of MSSql tables using a select statement based on a Where clause.

**tMSSqlTableList Standard properties**

These properties are used to configure tMSSqlTableList running in the Standard Job framework.

The Standard tMSSqlTableList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tMSSqlConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the Where clause to identify the tables to iterate on.</td>

<td></td>
</tr>
</tbody>
</table>
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with MSSql components, especially with tMSSqlConnection.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tMSSqlTableList related scenario, see Iterating on a DB table and listing its column names on page 2445.
tMysqlBulkExec

Offers gains in performance while executing the Insert operations on a MySQL or Aurora database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tMysqlBulkExec Standard Properties

These properties are used to configure tMysqlBulkExec running in the Standard Job framework.

The Standard tMysqlBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of the database that you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  **None:** No operation is carried out.  
  **Drop and create table:** The table is removed and created again.  
  **Create table:** The table does not exist and gets created.  
  **Create table if not exists:** The table is created if it does not exist.  
  **Drop table if exists and create:** The table is removed if it already exists and created again.  
  **Clear table:** The table content is deleted. You have the possibility to rollback the operation.  
  **Truncate table:** The table content is deleted. You do not have the possibility to rollback the operation. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed. |
| **Local file Name** | Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using **tMysqlBulkExec** is deployed. |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th><strong>Built-In</strong></th>
<th>You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
</table>
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td><strong>Enclosed by</strong></td>
<td>Character used to enclose text.</td>
</tr>
</tbody>
</table>

| **Action on data** | On the data of the table defined, you can perform:  
Insert records in table: Add new records to the table.  
Update records in table: Make changes to existing records.  
Replace records in table: Replace existing records with new ones.  
Ignore records in table: Ignore the existing records, or insert the new ones. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Records contain NULL value</strong></td>
<td>Check this box if you want to retrieve the null values from the input data flow. If you do not check this box, the null values from the input data flow will be considered as empty fields in the output data flow.</td>
</tr>
</tbody>
</table>
Encoding

Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

---

### Usage

**Usage rule**

This component is to be used along with **tMysqlOutputBulk** component. Used together, they can offer gains in performance while feeding a MySQL or Aurora database.

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

---

### Related scenarios

For use cases in relation with **tMysqlBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tMysqlClose

Closes the transaction committed in a Mysql database.

**tMysqlClose Standard properties**

These properties are used to configure tMysqlClose running in the Standard Job framework.

The Standard tMysqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Mysql components, especially with tMysqlConnection and tMysqlCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

This component is closed related to tMysqlConnection and tMysqlRollback. It is often used along with a tMysqlConnection componet since it closes an ongoing transaction.

For a scenario related to tMysqlClose, see tMysqlConnection on page 2451.
tMysqlColumnList

Iterates on all columns of a given Mysql table and lists column names.

**tMysqlColumnList Standard properties**

These properties are used to configure tMysqlColumnList running in the Standard Job framework.

The Standard tMysqlColumnList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Table name</td>
<td>Enter the name of the table.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>COLUMN_NAME: the name of the column currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DATA_TYPE: the data type of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_DEFAULT: the default value of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>IS_NULLABLE: nullability of the column currently iterated upon. This is a Flow variable and it returns YES if the column allows NULL; otherwise, NO.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_KEY: the key indicator of the column currently iterated upon. This is a Flow variable and it returns a string if the column is set to Key; otherwise it returns nothing.</td>
</tr>
<tr>
<td></td>
<td>CHARACTER_MAXIMUM_LENGTH: the maximum length in number of characters of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.</td>
</tr>
<tr>
<td></td>
<td>NUMERIC_PRECISION: the data precision of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data,</td>
</tr>
</tbody>
</table>
exact numeric data, integer data, or monetary data and NULL for other data types.

**NUMERIC_SCALE**: the scale in digits allowed in the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types.

**NB_COLUMN**: the number of columns iterated upon so far. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Mysql components, especially with <em>tMysqlConnection</em>.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2472 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 495. For more information on Dynamic settings and context variables, see *Talend Studio User Guide*. |

### Iterating on a DB table and listing its column names

The following Java scenario creates a five-component job that iterates on a given table name from a Mysql database using a Where clause and lists all column names present in the table.

- Drop the following components from the Palette onto the design workspace: *tMysqlConnection*, *tMysqlTableList*, *tMysqlColumnList*, *tFixedFlowInput*, and *tLogRow*.
- Connect *tMysqlConnection* to *tMysqlTableList* using an OnSubjobOk link.
• Connect `tMysqlTableList`, `tMysqlColumnList`, and `tFixedFlowInput` using `Iterate` links.
• Connect `tFixedFlowInput` to `tLogRow` using a `Row Main` link.

![Diagram showing connections between components](image)

• In the design workspace, select `tMysqlConnection` and click the `Component` tab to define its basic settings.
• In the `Basic settings` view, set the database connection details manually or select them from the context variable list, through a `Ctrl+Space` click in the corresponding field if you have stored them locally as Metadata DB connection entries.

For more information about Metadata, see *Talend Studio User Guide*.

![Example component settings](image)

In this example, we want to connect to a Mysql database called *customers*.

• In the design workspace, select `tMysqlTableList` and click the `Component` tab to define its basic settings.

![Example component settings](image)

• On the `Component list`, select the relevant Mysql connection component if more than one connection is used.
• Enter a Where clause using the right syntax in the corresponding field to iterate on the table name(s) you want to list on the console.
In this scenario, the table we want to iterate on is called customer.

- In the design workspace, select tMysqlColumnList and click the Component tab to define its basic settings.

- On the Component list, select the relevant Mysql connection component if more than one connection is used.

- In the Table name field, enter the name of the DB table you want to list its column names.

  In this scenario, we want to list the columns present in the DB table called customer.

- In the design workspace, select tFixedFlowInput and click the Component tab to define its basic settings.

- Set the Schema to Built-In and click the three-dot [...] button next to Edit Schema to define the data you want to use as input. In this scenario, the schema is made of two columns, the first for the table name and the second for the column name.

- Click OK to close the dialog box, and accept propagating the changes when prompted by the system. The defined columns display in the Values panel of the Basic settings view.

- Click in the Value cell for each of the two defined columns and press Ctrl+Space to access the global variable list.

- From the global variable list, select ((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE")) and ((String)globalMap.get("tMysqlColumnList_1_COLUMN_NAME")) for the TableName and ColumnName respectively.
- In the design workspace, select **tLogRow**.
- Click the **Component** tab and define the basic settings for **tLogRow** as needed.
- Save your job and press **F6** to execute it.

```
Starting job Column_Table_List at 00:55 17/11/2008

<table>
<thead>
<tr>
<th>customer</th>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>customer</td>
<td>First_Name</td>
</tr>
<tr>
<td>customer</td>
<td>Last_Name</td>
</tr>
<tr>
<td>customer</td>
<td>Address</td>
</tr>
<tr>
<td>customer</td>
<td>id_State</td>
</tr>
</tbody>
</table>

Job Column_Table_List ended at 00:55 17/11/2008. (exit code=0)
```

The name of the DB table is displayed on the console along with all its column names.
tMysqlCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.
tMysqlCommit validates the data processed through the Job into the connected DB.

**tMysqlCommit Standard properties**

These properties are used to configure tMysqlCommit running in the Standard Job framework.
The Standard tMysqlCommit component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlCommit component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tMysqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

2449
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tMysql* components, especially with the tMysqlConnection and tMysqlRollback components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Related scenario

For tMysqlCommit related scenario, see Inserting data in mother/daughter tables on page 2452.
tMysqlConnection

Opens a connection to the specified MySQL database for reuse in the subsequent subJob or subJobs.

**tMysqlConnection Standard properties**

These properties are used to configure tMysqlConnection running in the Standard Job framework.

The Standard tMysqlConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply.</strong></td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the tRunJob component. Using a shared connection together...</td>
</tr>
</tbody>
</table>
with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

| Specify a data source alias | Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**. |

Advanced settings

| Auto Commit | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

Usage

| Usage rule | This component is more commonly used with other **tMysql** components, especially with the **tMysqlCommit** and **tMysqlRollback** components. |

**Inserting data in mother/daughter tables**

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table.

As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as **innodb**:

1. In a command line editor, connect to your Mysql server.
2. Once connected to the relevant database, type in the following command to create the parent table:

   ```
   create table f1090_mum(id int not null auto_increment, name varchar(10), primary key(id)) engine=innodb;
   ```

3. Then create the second table:
create table f1090_baby (id_baby int not null, years int) engine=innodb;

Back in *Talend Studio*, the Job requires seven components including `tMysqlConnection` and `tMysqlCommit`.

**Linking the components**

**Procedure**

1. Drag and drop the following components from the Palette: a `tFileList`, a `tFileInputDelimited`, a `tMap`, a `tMysqlConnection`, a `tMysqlCommit` and two `tMysqlOutput`.
2. Connect `tMysqlConnection` to `tFileList` using an `OnComponentOk` link.
3. Connect `tFileList` to `tMysqlCommit` using an `OnComponentOk` link.
4. Connect the `tFileList` component to the input file component using an `Iterate` link as the name of the file to be processed will be dynamically filled in from the `tFileList` directory using a global variable.
5. Connect the `tFileInputDelimited` component to the `tMap` and dispatch the flow between the two output Mysql DB components. Use a `Row` link for each for these connections representing the main data flow.

**Configuring the components**

**Procedure**

1. Set the `tFileList` component properties, such as the directory name where files will be fetched from.
2. In the `tMysqlConnection` Component view, set the connection details manually or fetch them from the Repository if you centrally stored them as a Metadata DB connection entry. For more information about Metadata, see *Talend Studio User Guide*.
3. On the `tFileInputDelimited` component’s `Basic settings` panel, press `Ctrl+Space` bar to access the variable list. Set the `File Name` field to the global variable: `tFileList_1.CURRENT_FILEPATH`
4. Set the rest of the fields as usual, defining the row and field separators according to your file structure.

5. Then set the schema manually through the **Edit schema** feature or select the schema from the Repository. In Java version, make sure the data type is correctly set, in accordance with the nature of the data processed.

6. In the **tMap** Output area, add two output tables, one called mum for the parent table, the second called baby, for the child table.

   Drag the **Name** column from the Input area, and drop it to the mum table.

   Drag the **Years** column from the Input area and drop it to the baby table.

7. Make sure the mum table is on the top of the baby table as the order is determining for the flow sequence hence the DB insert to perform correctly.

   Connect the output row link to distribute correctly the flow to the relevant DB output component.

8. In the **Basic settings** tab of the two **tMysqlOutput** components, select the **Use an existing connection** check box to retrieve the **tMysqlConnection** details.

9. Set the **Table** name, making sure it corresponds to the correct table, in this example either **f1090_mum** or **f1090_baby**.
There is no action on the table as they are already created.
Select **Insert** as **Action on data** for both output components.
Click on Sync columns to retrieve the schema set in the **tMap**.

### 10. Switch to the Advanced settings tab of the DB output component corresponding to the child table (that is, `f1090_baby`).

- In the *id-baby* row of the **Additional columns** table, fill the **SQL expression** field with 
  "(Select Last_Insert_id())".
- Set the **Position** field to Before.
- Set the **Reference column** field to years.

These settings allow the `f1090_baby` table to use the ID key of the `f1090_mum` as its key.

### 11. Clear the **Extend insert** check box of both database output components.

## Executing the Job

### Procedure

1. Press **Ctrl + S** to save your Job.
2. Press **F6** to execute it.

![MySQL output](image.png)

The parent table *id* has been reused to feed the *id_baby* column.

## Rollback from inserting data in mother/daughter tables

### About this task

Based on **Inserting data in mother/daughter tables** on page 2452, insert a rollback function in order to prevent unwanted commit.
**Procedure**

1. Drag and drop `tMysqlRollback` to the design workspace. `tMysqlRollback` ensures that the transaction will not be partly committed.
2. Connect `tFileList` to `tMysqlRollback` with an `OnSubjobError` trigger.
3. Double-click `tMysqlRollback` to enter its Basic settings view.
4. From the Component List, select the connection component.

**Sharing a database connection between a parent Job and child Job**

This scenario shows how a database connection is shared between a parent Job and a child Job. The parent Job first calls the child Job to write some randomly generated data to a MySQL database, and then reads the data from the MySQL database and displays it on the console. A connection to the MySQL database is set up only once and used in both Jobs.

**Setting up the child Job**

**Adding and linking components**

**Procedure**

1. Add the following components by typing the component names on the design workspace or dropping them from the Palette:
   - a `tMysqlConnection` component, to open a connection to the MySQL database,
   - a `tRowGenerator`, to generate random input data,
   - a `tMysqlOutput` component, to write data to the MySQL database.
2. Connect the `tRowGenerator` component to the `tMysqlOutput` component using a Row > Main connection.
3. Connect the `tMysqlConnection` component to the `tRowGenerator` using a Trigger > OnSubjobOk connection.
Configuring the database connection

Procedure

1. Double-click the tMysqlConnection component to open its Basic settings view.

2. With the Property Type set to Built-In, specify the connection details in the relevant fields, including:
   - the host name or IP address of your database server
   - the listening port number
   - the database name
   - the user name and password for your database authentication.

   If you have stored your connection details under the Metadata node in the Repository tree view, you can simply drop your centralized metadata item onto the tMysqlConnection component. For information on how to centralize a database connection, see the chapter on managing metadata of the Talend Studio User Guide.

3. Select the Use or register a shared DB Connection check box so that the database connection open by this component can be shared across different Jobs. Then, enter a name for the shared connection between double quotes in the Shared DB Connection Name field, shared_mysql_connection in this example.
Configuring the input data

Procedure

1. Double-click the **tRowGenerator** component to open the Row Generator editor.

   ![Row Generator editor](image)

2. Click the [+] button to add four columns and set their properties:
   - **id**, type Integer, 2 characters long.
   - **firstName**, type String, 15 characters long
   - **lastName**, type String, 15 characters long
   - **city**, type String, 15 characters long

3. Define the function for each column:
   - For the **id** column, select **Numeric.sequence** from the **Function** list to generate sequence numbers.
   - For the **firstName** column, select **TalendDataGenerator.getFirstName** from the **Function** list to generate random first names.
   - For the **lastName** column, select **TalendDataGenerator.getLastName** from the **Function** list to generate random family names.
   - For the **city** column, select **TalendDataGenerator.getUsCity** from the **Function** list to generate random city names.

4. In the **Number of Rows for RowGenerator** field, specify the number of data rows you want to generate, 10 in this example.

5. Click the **Preview** button on the **Preview** tab to validate the generator settings.

6. When done, click **OK** to close the editor and click **Yes** when prompted to propagate the schema to the next component.
**Configuring the database output**

**Procedure**

1. Double-click the **tMysqlOutput** component to open its **Basic settings** view.

   ![Basic settings view](insert_image)

2. Select the **Use an existing connection** check box and, in case you have more than one connection component in the Job, select the connection component to be used from the **Component List** drop-down list.

3. In the **Table** field, enter the name of the database table you are going to write data to, **customers** in this example.

4. From the **Action on table** list, select the **Drop table if exists and create** option to ensure a clean table is created.

5. From the **Action on data** list, select **Insert**.

6. Click the [...] button next to **Edit schema** to check the output schema. If needed, click **Sync columns** to retrieve the schema from the preceding component.

7. Press **Ctrl+S** to save the Job.

**Setting up the parent Job**

**Arranging data flow for the parent Job**

**Procedure**

1. Add the following components by typing the component names on the design workspace or dropping them from the **Palette**:
   - a **tRunJob** component, to call the child Job,
   - a **tMysqlConnection** component, to open the MySQL database connection,
   - a **tMysqlInput** component, to read the data written to the MySQL database by the child Job.
   - a **tLogRow** component to display the data on the console,
   - a **tMysqlCommit** component to commit data upon transaction and close the database connection.

2. Connect the **tRunJob** component to the **tMysqlConnection** component using a **Trigger > OnSubjobOk** connection.

3. Connect the **tMysqlConnection** component to the **tMysqlInput** component using a **Trigger > OnSubjobOk** connection.

4. Connect the **tMysqlInput** component to the **tLogRow** component using a **Row > Main** connection.

5. Connect the **tMysqlInput** component to the **tMysqlCommit** component using a **Trigger > OnSubjobOk** connection.
Configuring the components

Procedure

1. Double-click the tRunJob component to open its Basic settings view.
   
   If a child Job has been already specified in the component, you can open its Basic settings view by right-clicking it and selecting Settings from the contextual menu, or by clicking the component and then selecting the Component tab.

2. Click the [...] button next to the Job field and select the child Job from the Repository Content dialog box. Leave all the other parameters as default.

3. In the Basic settings view of the tMysqlConnection component, select the Use or register a shared DB Connection check box. Then, in the Shared DB Connection Name field, enter the name of the shared connection defined in the child Job, shared_mysql_connection in this example.
   Leave all the other parameters blank or as default.
4. Double-click the tMysqlInput component to open its Basic settings view.

5. Select the Use an existing connection check box and, in case you have more than one connection component in the Job, select the connection component to be used from the Component List drop-down list.

6. Click the [...] button next to Edit schema to open the Schema editor, and define the same data structure as in the child Job.
When done, click **OK** to close the dialog and click **Yes** when prompted to propagate the schema to the next component.

7. Specify the table name in the **Table Name** list, and click **Guess Query** to get the query statement automatically filled in the **Query** field.

8. In the **Basic settings** view of the **tLogRow** component, select the **Table** mode to display the execution result in table cells.
   
   Leave the settings of the **tMysqlCommit** component unchanged.

**Execute the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.

2. Press **F6** or click the **Run** button on the **Run** console to execute the Job.

   ![Run Console](image)

   The Job first calls the child Job to write data to the database and then reads the data from the database and displays it on the console.

   ![Data Execution](image)
tMysqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. tMysqlInput reads a database and extracts fields based on a query. Then it passes on the field list to the next component via a **Main** row link.

**tMysqlInput Standard properties**

These properties are used to configure tMysqlInput running in the Standard Job framework. The Standard tMysqlInput component belongs to the Databases family.

The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see [Dynamic database components on page 608](#).

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| **Property type** | Either **Built-In** or **Repository**.  
**Built-In**: No property data stored centrally.  
**Repository**: Select the repository file where the properties are stored. |
| ![Icon](image) | Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.  
For more information about setting up and storing database connection parameters, see **Talend Studio User Guide**. |
| **DB version** | Select the version of the database to be used. |
| **Use an existing connection** | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Table Name</td>
<td>Name of the table to be read.</td>
</tr>
</tbody>
</table>

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
**Query type and Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*.

**Warning:**

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the *Use an existing connection* check box is selected.

### Advanced settings

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the *Use an existing connection* check box in the *Basic settings*.

**Note:** When you need to handle data of the time-stamp type 0000-00-00 00:00:00 using this component, set the parameter as: `noDatetimeStringSync=true&zeroDateTimeBehavior=convertToNull`.

**Enable stream**

Select this check box to enables streaming over buffering which allows the code to read from a large table without consuming a large amount of memory in order to optimize the performance.

This check box is available only when *Mysql 4* or *Mysql 5* is selected from the *DB Version* drop-down list.

**Trim all the String/Char columns**

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**

Remove leading and trailing whitespace from defined columns.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component covers all possible SQL queries for Mysql databases. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Writing columns from a MySQL database to an output file using tMysqlInput

In this scenario we will read certain columns from a MySQL database, and then write them to a table in a local output file.

Dragging and dropping components and linking them together

Procedure

1. Drop tMysqlInput and tFileOutputDelimited from the Palette onto the workspace.
2. Link **tMysqlInput** to **tFileOutputDelimited** using a **Row > Main** connection.

![Diagram showing connection between tMysqlInput and tFileOutputDelimited](image)

### Configuring the components

#### Procedure

1. Double-click **tMysqlInput** to open its **Basic Settings** view in the **Component** tab.

![Basic Settings view](image)

   - **Property Type**: Repository (if already stored in Metadata tree view), or Built-in (if not defined locally).
   - **Database**: Set to MySQL if using repository, otherwise enter details manually.
   - **Table Name**: 'employees'
   - **Query**: "SELECT employees.'id', employees.'first_name', employees.'salary'
   FROM employees"

2. From the **Property Type** list, select **Repository** if you have already stored the connection to database in the **Metadata** node of the **Repository** tree view. The property fields that follow are automatically filled in.

   For more information about how to store a database connection, see *Talend Studio User Guide*.

   If you have not defined the database connection locally in the **Repository**, fill in the details manually after selecting **Built-in** from the **Property Type** list.

3. Set the **Schema** as **Built-in** and click **Edit schema** to define the desired schema.

   The schema editor opens:
4. Click the [+] button to add the rows that you will use to define the schema, four columns in this example: id, first_name, city and salary.
   Under Column, click in the fields to enter the corresponding column names.
   Click the field under Type to define the type of data.
   Click OK to close the schema editor.

5. Next to the Table Name field, click the [...] button to select the database table of interest.
   A dialog box displays a tree diagram of all the tables in the selected database:

6. Click the table of interest and then click OK to close the dialog box.

7. Set the Query Type as Built-In.

8. In the Query box, enter the query required to retrieve the desired columns from the table.

   "SELECT employees.id, employees.first_name, employees.city, employees.salary
   FROM employees"

9. Double-click tFileOutputDelimited to set its Basic settings in the Component tab.
10. Next to the **File Name** field, click the [...] button to browse your directory to where you want to save the output file, then enter a name for the file.

Select the **Include Header** check box to retrieve the column names as well as the data.

11. Save the Job.

**Executing the Job**

The results below can be found after **F6** is pressed to run the Job.

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>id;first_name;city;salary</td>
</tr>
<tr>
<td>2</td>
<td>1;Martin;Sacramento;9011</td>
</tr>
<tr>
<td>3</td>
<td>2;Zachary;Atlanta;8118</td>
</tr>
<tr>
<td>4</td>
<td>3;James;Hartford;5087</td>
</tr>
<tr>
<td>5</td>
<td>4;Herbert;Charleston;9233</td>
</tr>
<tr>
<td>6</td>
<td>5;Herbert;Hartford;5289</td>
</tr>
<tr>
<td>7</td>
<td>6;Ulysses;Nashville;6269</td>
</tr>
</tbody>
</table>

As shown above, the output file is written with the desired column names and corresponding data, retrieved from the database:

**Note:**
The Job can also be run in the **Traces Debug** mode, which allows you to view the rows as they are being written to the output file, in the workspace.

**Using context parameters when reading a table from a database**

In this scenario, MySQL is used for demonstration purposes. We will read a table from a MySQL database, using a context parameter to refer to the table name.

**Dragging and dropping components and linking them together**

**Procedure**

1. Drop **tMysqlInput** and **tLogRow** from the **Palette** onto the workspace.
2. Link **tMysqlInput** to **tLogRow** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click tMysqlInput to open its Basic Settings view in the Component tab.

2. From the Property Type list, select Repository if you have already stored the connection to database in the Metadata node of the Repository tree view. The property fields that follow are automatically filled in.

   For more information about how to store a database connection, see Talend Studio User Guide. If you have not defined the database connection in the Repository, fill in the details manually after selecting Built-in from the Property Type list.

3. Set the Schema as Built-In and click Edit schema to define the desired schema.

   The schema editor opens:
4. Click the [+] button to add the rows that you will use to define the schema, seven columns in this example: `id`, `first_name`, `last_name`, `city`, `state`, `date_of_birth` and `salary`.

   Under Column, click the fields to enter the corresponding column names.

   Click the fields under Type to define the type of data.

   Click OK to close the schema editor.

5. Put the cursor in the Table Name field and press F5 for context parameter setting.

   For more information about context settings, see *Talend Studio User Guide*.

6. Keep the default setting in the Name field and type in the name of the database table in the Default value field, `employees` in this case.

7. Click Finish to validate the setting.

   The context parameter `context.TABLE` automatically appears in the Table Name field.

8. In the Query type list, select Built-In. Then, click Guess Query to get the query statement.

   In this use case, we want to read the records with the salary above 8000. Therefore, we add a Where clause and the final query statement is as follows:

   ```sql
   "SELECT "+context.TABLE+.`id`,
   "+context.TABLE+.`first_name`,
   "+context.TABLE+.`last_name`,
   "+context.TABLE+.`city`,
   "+context.TABLE+.`state`,
   "+context.TABLE+.`date_of_birth`,
   "+context.TABLE+.`salary"
   FROM "+context.TABLE"
   WHERE
   "+context.TABLE+.`salary` > 8000"
   ```

9. Double-click tLogRow to set its Basic Settings in the Component tab.
10. In the Mode area, select **Table (print values in cells of a table)** for a better display of the results.

11. Save the Job.

**Executing the Job**

The results below can be found after F6 is pressed to run the Job.

```
<table>
<thead>
<tr>
<th></th>
<th>first_name</th>
<th>last_name</th>
<th>city</th>
<th>state</th>
<th>date_of_birth</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Martin</td>
<td>Roosevelt</td>
<td>Sacramento</td>
<td>ND</td>
<td>18-10-1950</td>
<td>9011</td>
</tr>
<tr>
<td>2</td>
<td>Zachary</td>
<td>Johnson</td>
<td>Atlanta</td>
<td>ND</td>
<td>14-11-1978</td>
<td>8118</td>
</tr>
<tr>
<td>4</td>
<td>Herbert</td>
<td>Harrison</td>
<td>Charleston</td>
<td>AE</td>
<td>15-08-1963</td>
<td>9233</td>
</tr>
</tbody>
</table>
```

As shown above, the records with the salary greater than 8000 are retrieved.

**Reading data from databases through context-based dynamic connections**

In this scenario, MySQL is used for demonstration purposes. We will read data from database tables with the same data structure but in two different MySQL databases named **project_q1** and **project_q2** respectively. We will specify the connections to these databases dynamically at runtime, without making any modification to the Job.

**Dropping and linking the components**

**Procedure**

1. Drop two **tMysqlConnection**, a **tMysqlInput**, a **tLogRow**, and a **tMysqlClose** components onto the design workspace.
2. Link the first **tMysqlConnection** to the second **tMysqlConnection** and the second **tMysqlConnection** to **tMysqlInput** using **Trigger > On Subjob Ok** connections.
3. Link **tMysqlInput** to **tLogRow** using a **Row > Main** connection.
4. Link **tMysqlInput** to **tMysqlClose** using a **Trigger > On Subjob Ok** connection.
Creating a context variable

About this task

To be able to choose a database connection dynamically at runtime, we need to define a context variable, which will then be configure it in the Dynamic settings of the database input component.

Procedure

1. In the Contexts view, click the [+] button to add a row in the table, click in the Name field and enter a name for the variable, myConnection in this example.

2. From the Type list field, select List Of Value.

3. Click in the Value field and then click the button that appears in the field to open the Configure value of list dialog box.
4. In the **Configure value of list** dialog box, click the **New...** button to open the **New Value** dialog box, and enter the name of one of the connection components in the text field, *tMysqlConnection_1* in this example. Then click **OK** to close the dialog box.

Repeat this step to specify the other connection component name as another list item, *tMysqlConnection_2* in this example.

When done, click **OK** to close the **Configure Values** dialog box.

5. Select the check box next to the variable value field, and fill the **Prompt** field with the message you want to display at runtime, *Select a connection  component:* in this example.
Configuring the components

Procedure

1. Double-click the first `tMysqlConnection` component to show its Basic settings view, and set the connection details. For more information on the configuration of `tMysqlConnection`, see `tMysqlConnection` on page 2451.

   Note that we use this component to open a connection to a MySQL database named `project_q1`.

   ![tMysqlConnection_1](image)

2. Configure the second `tMysqlConnection` component in the same way, but fill the Database field with `project_q2` because we want to use this component to open a connection to another MySQL database, `project_q2`.

   ![tMysqlConnection_2](image)

3. Double-click the `tMysqlInput` component to show its Basic settings view.

   ![tMysqlInput_1](image)

4. Select the Use an existing connection check box, and leave the Component List box as it is.
5. Click the [...] button next to Edit schema to open the Schema dialog box and define the data structure of the database table to read data from.

![Schema of tMysqlInput_1](image1)

In this example, the database table structure is made of four columns, id (type Integer, 2 characters long), firstName (type String, 15 characters long), lastName (type String, 15 characters long), and city (type String, 15 characters long). When done, click OK to close the dialog box and propagate the schema settings to the next component.

6. Fill the Table field with the database table name, customers in this example, and click Guess Query to generate the query statement corresponding to your table schema in the Query field.

7. In the Dynamic settings view, click the [+] button to add a row in the table, and fill the Code field with the code script of the context variable you just created, " + context.myConnection + " in this example.

![tMysqlInput_1](image2)

8. In the Basic settings view of the tLogRow component, select the Table option for better display effect of the Job execution result.
9. In the Dynamic settings view of the tMysqlClose component, do exactly the same as in the Dynamic settings view of the tMysqlInput component.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job and press F6 or click Run to launch it.
   A dialog box appears prompting you to specify the connection component you want to use.
2. Select the connection component, tMysqlConnection_1, and click OK.

The data read from database project_q1 is displayed in the Run console.
3. Press **F6** or click **Run** to launch your Job again. When prompted, select the other connection component, **tMysqlConnection_2**, to read data from the other database, **project_q2**.

The data read from database **project_q2** is displayed in the **Run** console.

```
<table>
<thead>
<tr>
<th>id</th>
<th>firstName</th>
<th>lastName</th>
<th>city</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Warren</td>
<td>Reagan</td>
<td>Atlanta</td>

<td>Harry</td>
<td>Ford</td>
<td>Providence</td>
</tr>
</tbody>
</table>
```
tMysqlLastInsertId

Obtains the primary key value of the record that was last inserted in a Mysql table by a user. tMysqlLastInsertId fetches the last inserted ID from a selected MySQL Connection.

**tMysqlLastInsertId Standard properties**

These properties are used to configure tMysqlLastInsertId running in the Standard Job framework. The Standard tMysqlLastInsertId component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>

Getting the ID for the last inserted record with tMysqlLastInsertId

The following Java scenario creates a job that opens a connection to Mysql database, writes the defined data into the database, and finally fetches the last inserted ID on the existing connection.

- Drop the following components from the Palette onto the design workspace: tMysqlConnection, tMySqlCommit, tFileInputDelimited, tMySqlOutput, tMysqlLastInsertId, and tLogRow.
- Connect tMySqlConnection to tFileInputDelimited using an OnSubjobOk link.
- Connect tFileInputDelimited to tMySqlCommit using an OnSubjobOk link.
- Connect tFileInputDelimited to the three other components using Row Main links.

- In the design workspace, select tMysqlConnection.
- Click the Component tab to define the basic settings for tMysqlConnection.
- In the Basic settings view, set the connection details manually or select them from the context variable list, through a Ctrl+Space click in the corresponding field if you stored them locally as Metadata DB connection entries. For more information about Metadata, see Talend Studio User Guide.
• In the design workspace, select **tMysqlCommit** and click the **Component** tab to define its basic settings.
• On the **Component List**, select the relevant **tMysqlConnection** if more than one connection is used.
• In the design workspace, select **tFileInputDelimited**.
• Click the **Component** tab to define the basic settings of **tFileInputDelimited**.

![](image1.png)

- Fill in a path to the processed file in the **File Name** field. The file used in this example is *Customers*.
- Define the **Row separator** that allow to identify the end of a row. Then define the **Field separator** used to delimit fields in a row.
- Set the header, the footer and the number of processed rows as necessary. In this scenario, we have one header.
- Click the three-dot button next to **Edit Schema** to define the data to pass on to the next component.

**Related topics:** [Talend Studio User Guide](#).

![](image2.png)

In this scenario, the schema consists of two columns, *name* and *age*. The first holds three employees' names and the second holds the corresponding age for each.

• In the design workspace, select **tMySqlOutput**.
• Click the **Component** tab to define the basic settings of **tMySqlOuptput**.
Select the **Use an existing connection** check box.

In the **Table** field, enter the name of the table where to write the employees’ list, in this example: *employee*.

Select relevant actions on the **Action on table** and **Action on data** lists. In this example, no action is carried out on table, and the action carried out on data is *Insert*.

Click **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted into the MySql database table consists of the two columns *name* and *age*.

In the design workspace, select **tMySqlLastInsertId**.

Click the **Component** tab to define the basic settings of **tMySqlLastInsertId**.

On the **Component List**, select the relevant **tMySqlConnection**, if more than one connection is used.

Click **Sync columns** to synchronize columns with the previous component. In the output schema of **tMySqlLastInsertId**, you can see the read-only column *last_insert_id* that will fetch the last inserted ID on the existing connection.
You can select the data type *Long* from the *Type* drop-down list in case of a huge number of entries.

- In the design workspace, select *tLogRow* and click the *Component* tab to define its basic settings. For more information, see *tLogRow* on page 1971.
- Save your job and press **F6** to execute it.

```
Starting job lastinserted at 11:12 01/09/2008.

<table>
<thead>
<tr>
<th>name</th>
<th>age</th>
<th>last_insert_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marie</td>
<td>24</td>
<td>40</td>
</tr>
<tr>
<td>Patrick</td>
<td>22</td>
<td>41</td>
</tr>
<tr>
<td>Pierrick</td>
<td>27</td>
<td>42</td>
</tr>
</tbody>
</table>
```

Job *lastinserted* ended at 11:12 01/09/2008. [exit code=0]

tMysqlLastInsertId fetched the last inserted ID for each line on the existing connection.
tMysqlLookupInput

Reads a MySQL database and extracts fields based on a query.

It passes on the extracted data to tMap in order to provide the lookup data to the main flow. It must be directly connected to a tMap component and requires this tMap to use **Reload at each row** or **Reload at each row (cache)** for the lookup flow.

This component also allows you to connect and read data from a RDS Aurora or a RDS MySQL database.
tMysqlOutput

Writes, updates, makes changes or suppresses entries in a database.

tMysqlOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tMysqlOutput Standard properties**

These properties are used to configure tMysqlOutput running in the Standard Job framework.
The Standard tMysqlOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Property type | Either **Built-In** or **Repository**.  
**Built-In**: No property data stored centrally.  
**Repository**: Select the repository file where the properties are stored. |
| DB Version | Select the MySQL version you are using. |
| ![Icon] | Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.  
For more information about setting up and storing database connection parameters, see **Talend Studio User Guide**. |
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide.*

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
**Default:** No operation is carried out.  
**Drop and create a table:** The table is removed and created again.  
**Create a table:** The table does not exist and gets created.  
**Create a table if not exists:** The table is created if it does not exist.  
**Drop a table if exists and create:** The table is removed if it already exists and created again.  
**Clear a table:** The table content is deleted.  
**Truncate table:** The table content is quickly deleted. However, you will not be able to rollback the operation. |
| **Action on data** | On the data of the table defined, you can perform:  
**Insert:** Add new entries to the table. If duplicates are found, the job stops.  
**Update:** Make changes to existing entries.  
**Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.  
**Update or insert:** Update the record with the given reference. If the record does not exist, a new record would be inserted.  
**Delete:** Remove entries corresponding to the input flow. |

2487
**Replace**: Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.

**Insert or update on duplicate key or unique index**: Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.

**Insert Ignore**: Add only new rows to prevent duplicate key errors.

**Warning**: You must specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the **Use field options** check box and then in the **Key in update** column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the **Key in delete** column for the deletion operation.

---

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

---

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
### Die on error

This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a **Row > Rejects** link.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

**Warning:**

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**Note:**

You can press Ctrl+Space to access a list of predefined global variables.

#### Extend Insert

Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.

**Number of rows per insert:** enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.

**Note:**

This option is not compatible with the **Reject** link. You should therefore clear the check box if you are using a **Row > Rejects** link with this component.

**Warning:**

If you are using this component with **tMysqlLastInsertID**, ensure that the **Extend Insert** check box in **Advanced Settings** is not selected. **Extend Insert** allows for batch loading, however, if the check box is selected, only the ID of the last line of the last batch will be returned.

#### Use Batch

Select this check box to activate the batch mode for data processing.
<table>
<thead>
<tr>
<th><strong>Note:</strong></th>
<th>This check box is available only when you have selected, the Update or the Delete option in the <strong>Action on data</strong> field.</th>
</tr>
</thead>
</table>

| **Batch Size** | Specify the number of records to be processed in each batch.  
This field appears only when the **Use batch mode** check box is selected. |
| **Commit every** | Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level. |
| **Additional Columns** | This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing. |
| **Name:** | Type in the name of the schema column to be altered or inserted. |
| **SQL expression:** | Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column. |
| **Position:** | Select **Before, Replace** or **After**, depending on the action to be performed on the reference column. |
| **Reference column:** | Type in a reference column that **tMySqlOutput** can use to locate or replace the new column, or the column to be modified. |
| **Use field options** | Select this check box to customize a request, particularly if multiple actions are being carried out on the data. |
| **Use Hint Options** | Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are:  
- **HINT**: specify the hint you need, using the syntax /*+ */.  
- **POSITION**: specify where you put the hint in a SQL statement.  
- **SQL STMT**: select the SQL statement you need to use. |
| **Enable debug mode** | Select this check box to display each step involved in the process of writing data in the database. |
| **Use duplicate key update mode insert** | Updates the values of the columns specified, in the event of duplicate primary keys.  
**Column**: Between double quotation marks, enter the name of the column to be updated.  
**Value**: Enter the action you want to carry out on the column. |
Note:
To use this option you must first of all select the Insert mode in the Action on data list found in the Basic Settings view.

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong>: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

**Usage**

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2500. |

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic |
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Inserting a column and altering data using tMysqlOutput

This Java scenario is a three-component job that aims at creating random data using a tRowGenerator, duplicating a column to be altered using the tMap component, and eventually altering the data to be inserted based on an SQL expression using the tMysqlOutput component.

• Drop the following components from the Palette onto the design workspace: tRowGenerator, tMap and tMySQLOutput.
• Connect tRowGenerator, tMap, and tMysqlOutput using the Row Main link.

• In the design workspace, select tRowGenerator to display its Basic settings view.

• Click the Edit schema three-dot button to define the data to pass on to the tMap component, two columns in this scenario, name and random_date.
• Click **OK** to close the dialog box.
• Click the **RowGenerator Editor** three-dot button to open the editor and define the data to be generated.

• Click in the corresponding **Functions** fields and select a function for each of the two columns, `getFirstName` for the first column and `getRandomDate` for the second column.
• In the **Number of Rows for Rowgenerator** field, enter 10 to generate ten first name rows and click **Ok** to close the editor.
• Double-click the **tMap** component to open the Map editor. The Map editor opens displaying the input metadata of the **tRowGenerator** component.
In the Schema editor panel of the Map editor, click the plus button of the output table to add two rows and define the first as `random_date` and the second as `random_date1`.

In this scenario, we want to duplicate the `random_date` column and adapt the schema in order to alter the data in the output component.

- In the Map editor, drag the `random_date` row from the input table to the `random_date` and `random_date1` rows in the output table.
• Click OK to close the editor.

• In the design workspace, double-click the tMysqlOutput component to display its Basic settings view and set its parameters.

• Set Property Type to Repository and then click the three-dot button to open the Repository content dialog box and select the correct DB connection. The connection details display automatically in the corresponding fields.

**Note:**

If you have not stored the DB connection details in the Metadata entry in the Repository, select Built-in on the property type list and set the connection detail manually.

• Click the three-dot button next to the Table field and select the table to be altered, Dates in this scenario.
• On the Action on table list, select Drop table if exists and create, select Insert on the Action on data list.
• If needed, click Sync columns to synchronize with the columns coming from the tMap component.
• Click the Advanced settings tab to display the corresponding view and set the advanced parameters.

In the Additional Columns area, set the alteration to be performed on columns.

In this scenario, the One_month_later column replaces random_date_1. Also, the data itself gets altered using an SQL expression that adds one month to the randomly picked-up date of the random_date_1 column. ex: 2007-08-12 becomes 2007-09-12.

- Enter One_Month_Later in the Name cell.
- In the SQL expression cell, enter the relevant addition script to be performed, "adddate (Random_date, interval 1 month)" in this scenario.
- Select Replace on the Position list.
- Enter Random_date1 on the Reference column list.

Note:
For this job we duplicated the random_date_1 column in the DB table before replacing one instance of it with the One_Month_Later column. The aim of this workaround was to be able to view upfront the modification performed.

• Save your job and press F6 to execute it.

The new One_month_later column replaces the random_date1 column in the DB table and adds one month to each of the randomly generated dates.
Updating data using tMysqlOutput

This Java scenario describes a two-component Job that updates data in a MySQL table according to that in a delimited file.

- Drop tFileInputDelimited and tMysqlOutput from the Palette onto the design workspace.
- Connect the two components together using a Row Main link.

- Double-click tFileInputDelimited to display its Basic settings view and define the component properties.
- From the Property Type list, select Repository if you have already stored the metadata of the delimited file in the Metadata node in the Repository tree view. Otherwise, select Built-In to define manually the metadata of the delimited file.

For more information about storing metadata, see Talend Studio User Guide.
• In the **File Name** field, click the three-dot button and browse to the source delimited file that contains the modifications to propagate in the MySQL table.

In this example, we use the `customer_update` file that holds four columns: `id`, `CustomerName`, `CustomerAddress` and `idState`. Some of the data in these four columns is different from that in the MySQL table.

![Customer data](image)

- Define the row and field separators used in the source file in the corresponding fields.
- If needed, set **Header**, **Footer** and **Limit**.

  In this example, **Header** is set to 1 since the first row holds the names of columns, therefore it should be ignored. Also, the number of processed lines is limited to 2000.

- Click the three-dot button next to **Edit Schema** to open a dialog box where you can describe the data structure of the source delimited file that you want to pass to the component that follows.

![Edit Schema](image)

- Select the **Key** check box(es) next to the column name(s) you want to define as key column(s).

**Note:**

It is necessary to define at least one column as a key column for the Job to be executed correctly. Otherwise, the Job is automatically interrupted and an error message displays on the console.

- In the design workspace, double-click **tMysqlOutput** to open its **Basic settings** view where you can define its properties.
Click **Sync columns** to retrieve the schema of the preceding component. If needed, click the three-dot button next to **Edit schema** to open a dialog box where you can check the retrieved schema.

From the **Property Type** list, select **Repository** if you have already stored the connection metadata in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** to define manually the connection information.

For more information about storing metadata, see *Talend Studio User Guide*.

- Fill in the database connection information in the corresponding fields.
- In the **Table** field, enter the name of the table to update.
- From the **Action on table** list, select the operation you want to perform, **Default** in this example since the table already exists.
- From the **Action on data** list, select the operation you want to perform on the data, **Update** in this example.
- Save your Job and press **F6** to execute it.
Using your DB browser, you can verify if the MySQL table, `customers`, has been modified according to the delimited file.

In the above example, the database table has always the four columns `id`, `CustomerName`, `CustomerAddress` and `idState`, but certain fields have been modified according to the data in the delimited file used.

### Retrieving data in error with a Reject link

This scenario describes a four-component Job that carries out migration from a customer file to a MySQL database table and redirects data in error towards a CSV file using a **Reject** link.
In the **Repository**, select the customer file metadata that you want to migrate and drop it onto the workspace. In the **Components** dialog box, select **tFileInputDelimited** and click **OK**. The component properties will be filled in automatically.

If you have not stored the information about your customer file under the **Metadata** node in the **Repository**, drop a **tFileInputDelimited** component from the family **File > Input**, in the **Palette**, and fill in its properties manually in the **Component** tab.

From the **Palette**, drop a **tMap** from the **Processing** family onto the workspace.

In the **Repository**, expand the **Metadata** node, followed by the **Db Connections** node and select the connection required to migrate your data to the appropriate database. Drop it onto the workspace. In the **Components** dialog box, select **tMysqlOutput** and click **OK**. The database connection properties will be automatically filled in.

If you have not stored the database connection details under the **Db Connections** node in the **Repository**, drop a **tMysqlOutput** from the **Databases** family in the **Palette** and fill in its properties manually in the **Component** tab.

For more information, see **Talend Studio User Guide**.

From the **Palette**, select a **tFileOutputDelimited** from the **File > Output** family, and drop it onto the workspace.

Link the **customers** component to the **tMap** component, and the **tMap** and **Localhost** with a **Row Main** link. Name this second link **out**.

Link the **Localhost** to the **tFileOutputDelimited** using a **Row > Reject** link.

Double-click the **customers** component to display the **Component** view.

In the **Property Type** list, select **Repository** and click the [...] button in order to select the metadata containing the connection to your file. You can also select the **Built-in** mode and fill in the fields manually.

Click the [...] button next to the **File Name** field, and fill in the path and the name of the file you want to use.

In the **Row** and **Field Separator** fields, type in between inverted commas the row and field separator used in the file.

In the **Header**, **Footer** and **Limit** fields, type in the number of headers and footers to ignore, and the number of rows to which processing should be limited.

In the **Schema** list, select **Repository** and click the [...] button in order to select the schema of your file, if it is stored under the **Metadata** node in the **Repository**. You can also click the [...] button next to the **Edit schema** field, and set the schema manually.

The schema is as follows:
• Double-click the **tMap** component to open its editor.

• Select the *id*, *CustomerName*, *CustomerAddress*, *idState*, *id2*, *RegTime* and *RegisterTime* columns on the table on the left and drop them on the **out** table, on the right.
In the Schema editor area, at the bottom of the tMap editor, in the right table, change the length of the CustomerName column to 28 to create an error. Thus, any data for which the length is greater than 28 will create errors, retrieved with the Reject link.

Click OK.

In the workspace, double-click the output Localhost component to display its Component view.

In the Property Type list, select Repository and click the [...] button to select the connection to the database metadata. The connection details will be automatically filled in. You can also select the Built-in mode and set the fields manually.

In the Table field, type in the name of the table to be created. In this scenario, we call it customers_data.

In the Action on data list, select the Create table option.

Click the Sync columns button to retrieve the schema from the previous component.

Make sure the Die on error check box isn’t selected, so that the Job can be executed despite the error you just created.

Click the Advanced settings tab of the Component view to set the advanced parameters of the component.
• Deselect the **Extend Insert** check box which enables you to insert rows in batch, because this option is not compatible with the **Reject** link.
• Double-click the **tFileOutputDelimited** component to set its properties in the **Component** view.

• Click the [...] button next to the **File Name** field to fill in the path and name of the output file.
• Click the **Sync columns** button to retrieve the schema of the previous component.
• Save your Job and press **F6** to execute it.
The data in error are sent to the delimited file, as well as the error type met. Here, we have: **Data truncation**.
tMysqlOutputBulk

Writes a file with columns based on the defined delimiter and the MySQL or Aurora standards.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tMysqlOutputBulk Standard properties

These properties are used to configure tMysqlOutputBulk running in the Standard Job framework.

The Standard tMysqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated. This file is generated on the same machine where the Studio is installed or where the Job using tMysqlOutputBulk is deployed.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</td>
</tr>
<tr>

<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Inserting transformed data in MySQL database

This scenario describes a four-component job which aims at fueling a database with data contained in a file, including transformed data. Two steps are required in this job, first step is to create the file, that will then be used in the second step. The first step includes a tranformation phase of the data included in the file.
**Dropping and linking components**

**Procedure**

1. Drag and drop a `tRowGenerator`, a `tMap`, a `tMysqlOutputBulk` as well as a `tMysqlBulkExec` component.
2. Connect the main flow using `row Main` links.
3. And connect the start component (`tRowGenerator` in this example) to the `tMysqlBulkExec` using a trigger connection, of type `OnComponentOk`.

**Configuring the components**

**Procedure**

1. A `tRowGenerator` is used to generate random data. Double-click on the `tRowGenerator` component to launch the editor.
2. Define the schema of the rows to be generated and the nature of data to generate. In this example, the `clients` file to be produced will contain the following columns: `ID`, `First Name`, `Last Name`, `Address`, `City` which all are defined as string data but the ID that is of integer type.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th></th>
<th>Length</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td></td>
<td>int</td>
<td></td>
<td>10</td>
<td>sequence</td>
<td>1</td>
</tr>
<tr>
<td>FirstName</td>
<td></td>
<td>String</td>
<td></td>
<td>2</td>
<td>getFirstName</td>
<td>Jimmy</td>
</tr>
<tr>
<td>LastName</td>
<td></td>
<td>String</td>
<td></td>
<td>14</td>
<td>TalendData...</td>
<td>Reagan</td>
</tr>
<tr>
<td>Address</td>
<td></td>
<td>String</td>
<td></td>
<td>14</td>
<td>getUsStreet</td>
<td>Milpas Street</td>
</tr>
<tr>
<td>City</td>
<td></td>
<td>String</td>
<td></td>
<td>14</td>
<td>getUsCity</td>
<td>Juneau</td>
</tr>
</tbody>
</table>

Some schema information don’t necessarily need to be displayed. To hide them away, click on `Columns` list button next to the toolbar, and uncheck the relevant entries, such as `Precision` or `Parameters`.

Use the plus button to add as many columns to your schema definition. Click the Refresh button to preview the first generated row of your output.

3. Then select the `tMap` component to set the transformation.
4. Drag and drop all columns from the input table to the output table.
5. Apply the transformation on the LastName column by adding .toUpperCase() in its expression field.

Then, click OK to validate the transformation.

6. Double-click on the tMysqlOutputBulk component.

7. Define the name of the file to be produced in File Name field. If the delimited file information is stored in the Repository, select it in Property Type field, to retrieve relevant data. In this use case the file name is clients.txt.

The schema is propagated from the tMap component, if you accepted it when prompted.

8. In this example, don’t include the header information as the table should already contain it.

9. Click OK to validate the output.

10. Then double-click on the tMysqlBulkExec component to set the INSERT query to be executed.

11. Define the database connection details. We recommend you to store this type of information in the Repository, so that you can retrieve them at any time for any Job.

12. Set the table to be filled in with the collected data, in the Table field.

13. Fill in the column delimiters in the Field terminated by area.

14. Make sure the encoding corresponds to the data encoding.

**Saving and executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.

2. Press F6 or click Run on the Run tab to execute the Job.
The `clients` database table is filled with data from the file including upper-case `last name` as transformed in the job.

**Results**

For simple Insert operations that don’t include any transformations, the use of `tMysqlOutputBulkExec` allows you to skip a step in the process and thus improves performance.

Related topic: `tMysqlOutputBulkExec Standard properties` on page 2512
tMysqlOutputBulkExec

Executes the Insert action in the specified MySQL or Aurora database.

As a dedicated component, tMysqlBulkExec improves performance when performing Insert operations to a MySQL or Aurora database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component.

**tMysqlOutputBulkExec Standard properties**

These properties are used to configure tMysqlOutputBulkExec running in the Standard Job framework.

The Standard tMysqlOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

This file is generated on the same machine where the Studio is installed or where the Job using tMysqlOutputBulkExec is deployed. Then it is loaded to the database specified by Host field.

<table>
<thead>
<tr>
<th><strong>Append</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Select the check box for this option to append new rows to the end of the file.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content window**.

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).
### Advanced settings

</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</td>
</tr>
</tbody>
</table>
Inserting data in bulk in MySQL database

This scenario describes a two-component Job which carries out the same operation as the one described for `tMysqlOutputBulk` Standard properties on page 2506 and `tMysqlBulkExec` Standard Properties on page 2438, although no data is transformed.

- Drop a `tRowGenerator` and a `tMysqlOutputBulkExec` component from the Palette to the design workspace.
- Connect the components using a link such as Row > Main.
- Set the `tRowGenerator` parameters the same way as in Inserting transformed data in MySQL database on page 2508. The schema is made of four columns including: ID, First Name, Last Name, Address and City.
- In the workspace, double-click the `tMysqlOutputBulkExec` to display the Component view and set the properties.

• Define the database connection details in the corresponding fields, if necessary. Consult the recommendations detailed in Inserting transformed data in MySQL database on page 2508, concerning the conservation of connection details in the Repository, under the Metadata node. In the component view, select Repository in the Property Type field and then select the appropriate connection in the adjacent field. The following fields will be filled in automatically.

For further information, see Talend Studio User Guide.

• In the Action on table field, select the None option as you want to insert the data into a table which already exists.
• In the Table field, enter the name of the table you want to populate, the name being clients in this example.
• In the Local filename field, indicate the access path and the name of the file which contains the data to be added to the table. In this example, the file is clients.txt.
• Click on the Advanced settings tab to define the component’s advanced parameters.
In the **Action on data** list, select the **Insert records in table** to insert the new data in the table.

- Press **F6** to run the Job.

The result should be pretty much the same as in *Inserting transformed data in MySQL database* on page 2508, but the data might differ as these are regenerated randomly everytime the Job is run.
tMysqlRollback

Cancels the transaction commit in the connected MySQL database to avoid committing part of a transaction involuntarily.

**tMysqlRollback Standard properties**

These properties are used to configure tMysqlRollback running in the Standard Job framework.

The Standard tMysqlRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tMysqlConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tMysql* components, especially with the <strong>tMysqlConnection</strong> and <strong>tMysqlCommit</strong> components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection</td>
</tr>
</tbody>
</table>
parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
tMysqlRow

Executes the stated SQL query on the specified MySQL database.

Depending on the nature of the query and the database, tMysqlRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tMysqlRow is the specific component for MySQL database query. It implements a flow in the Job design although it doesn’t provide output.

**tMysqlRow Standard properties**

These properties are used to configure tMysqlRow running in the Standard Job framework.

The Standard tMysqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the MySQL version that you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Name of the table to be processed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td>Guess Query</td>
<td>Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td>Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</td>
</tr>
<tr>
<td>Specify a data source alias</td>
<td>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.</td>
</tr>
<tr>
<td></td>
<td>If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.</td>
</tr>
<tr>
<td></td>
<td>This check box is not available when the Use an existing connection check box is selected.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Propagate QUERY’s recordset</td>
<td>Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the use column list.</td>
</tr>
</tbody>
</table>

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.
Use PreparedStatement

Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by "?" in the SQL instruction of the Query field in the Basic Settings tab.

Parameter Index: Enter the parameter position in the SQL instruction.
Parameter Type: Enter the parameter type.
Parameter Value: Enter the parameter value.

Note:
This option is very useful if you need to execute the same query several times. Performance levels are increased.

Commit every

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

StatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

QUERY: the query statement being processed. This is a Flow variable and it returns a string.
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component offers the flexibility of the DB query and covers all possible SQL queries.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for
Removing and regenerating a MySQL table index

This scenario describes a four-component job that removes a table index, applies a select insert action onto a table then regenerates the index.

Linking the components

Procedure
1. Select and drop the following components onto the design workspace: tMysqlRow (x2), tRowGenerator, and tMysqlOutput.
2. Link the first tMysqlRow to tRowGenerator using an OnComponentOk connection.
3. Link tRowGenerator to tMysqlOutput using a Row > Main connection.
4. Link tRowGenerator to the second tMysqlRow using an OnSubjobOk connection.

Configuring the components

Procedure
1. Select the tMysqlRow to fill in the DB Basic settings.
2. In Property type as well in Schema, select the relevant DB entry in the list.
   The DB connection details and the table schema are accordingly filled in.
3. Propagate the properties and schema details onto the other components of the Job. The query being stored in the Metadata area of the Repository, you can also select Repository in the Query type field and the relevant query entry.

4. If you didn’t store your query in the Repository, type in the following SQL statement to alter the database entries: drop index <index_name> on <table_name>

5. Select the second tMysqlRow component, check the DB properties and schema.

6. Type in the SQL statement to recreate an index on the table using the following statement: create index <index_name> on <table_name> (<column_name>)

   The tRowGenerator component is used to generate automatically the columns to be added to the DB output table defined.

7. Select the tMysqlOutput component and fill in the DB connection properties either from the Repository or manually the DB connection details are specific for this use only. The table to be fed is named: comprehensive.

8. The schema should be automatically inherited from the data flow coming from the tLogRow. Edit the schema to check its structure and check that it corresponds to the schema expected on the DB table specified.

   The Action on table is None and the Action on data is Insert.

   No additional Columns is required for this job.

### Executing the Job

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to run the job.

   If you manage to watch the action on DB data, you can notice that the index is dropped at the start of the job and recreated at the end of the insert action.

   Related topics: tDBSQLRow Standard properties on page 632.

### Using PreparedStatement objects to query data

This scenario describes a four component job which allows you to link a table column with a client file. The MySQL table contains a list of all the American States along with the State ID, while the file contains the customer information including the ID of the State in which they live. We want to retrieve the name of the State for each client, using an SQL query. In order to process a large volume of data quickly, we use a PreparedStatement object which means that the query is executed only once rather than against each row in turn. Then each row is sent as a parameter. Note that PreparedStatement object can also be used in avoiding SQL injection.

For this scenario, we use a file and a database for which we have already stored the connection and properties in the Repository metadata. For further information concerning the creation of metadata in delimited files, the creation of database connection metadata and the usage of metadata, see Talend Studio User Guide.

### Linking the components

**Procedure**

1. In the Repository, expand the Metadata and File delimited nodes.
2. Select the metadata which corresponds to the client file and slide the metadata onto the workspace. Here, we are using the *customers* metadata.

3. Double-click `tFileInputDelimited` in the *Components* dialog box to add `tFileInputDelimited` to the workspace, with the relevant fields filled by the metadata file.

4. Drop `tMysqlRow`, `tParseRecordSet` and `tFileOutputDelimited` onto the workspace.

5. Link `tFileInputDelimited` to `tMysqlRow` using a Row > Main connection.

6. Link `tMysqlRow` to `tParseRecordSet` using a Row > Main connection.

7. Link `tParseRecordSet` to `tFileOutputDelimited` using a Row > Main connection.

### Configuring the components

**Procedure**

1. Double-click `tFileInputDelimited` to open its Basic settings view.

2. In the Schema list, select Built-in so that you can modify the component’s schema. Then click on [...] next to the Edit schema field to add a column into which the name of the State will be inserted.
3. Click on the [+] button to add a column to the schema. Rename this column `LabelStateRecordSet` and select `Object` from the `Type` list. Click `OK` to save your modifications.

4. From the Palette, select the `tMysqlRow`, `tParseRecordSet` and `tFileOutputDelimited` components and drop them onto the workspace.

5. Double click `tMysqlRow` to set its properties in the `Basic settings` tab of the Component view.
6. In the Property Type list, select Repository and click on the [...] button to select a database connection from the metadata in the Repository. The DB Version, Host, Port, Database, Username and Password fields are completed automatically. If you are using the Built-in mode, complete these fields manually.

7. From the Schema list, select Built-in to set the schema properties manually and add the LabelStateRecordSet column, or click directly on the Sync columns button to retrieve the schema from the preceding component.

8. In the Query field, enter the SQL query you want to use. Here, we want to retrieve the names of the American States from the LabelState column of the MySQL table, us_state: "SELECT LabelState FROM us_state WHERE idState=?". The question mark, ",?", represents the parameter to be set in the Advanced settings tab.

9. Click Advanced settings to set the components advanced properties.

10. Select the Propagate QUERY’s recordset check box and select the LabelStateRecordSet column from the use column list to insert the query results in that column.

11. Select the Use PreparedStatement check box and define the parameter used in the query in the Set PreparedStatement Parameters table.

12. Click on the [+] button to add a parameter.
   a) In the Parameter Index cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.
   b) In the Parameter Type cell, enter the type of parameter. Here, the parameter is a whole number, hence, select Int from the list.
   c) In the Parameter Value cell, enter the parameter value. Here, we want to retrieve the name of the State based on the State ID for every client in the input file. Hence, enter "row1.idState".

13. Double click tParseRecordSet to set its properties in the Basic settings tab of the Component view.
a) From the **Prev. Comp. Column list**, select the preceding components column for analysis. In this example, select `LabelStateRecordSet`.

b) Click on the **Sync columns** button to retrieve the schema from the preceding component. The **Attribute table** is automatically completed with the schema columns.

c) In the **Attribute table**, in the **Value** field which corresponds to the `LabelStateRecordSet`, enter the name of the column containing the State names to be retrieved and matched with each client, within double quotation marks. In this example, enter "LabelState".

14. Double click **tFileOutputDelimited** to set its properties in the **Basic settings** tab of the **Component** view.

   a) In the **File Name field**, enter the access path and name of the output file.

   b) Click **Sync columns** to retrieve the schema from the preceding component.

---

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run it.

**Results**

A column containing the name of the American State corresponding to each client is added to the file.
Combining two flows for selective output

In this scenario, a flow generated by `tFixedFlowInput` is combined with a flow from the Mysql database. The source flow contains `id` and `age` fields while the Mysql table contains `id` and `name`. We want to retrieve the `age` data of the source flow and combine it with the `id` and `name` records from the Mysql table based on `id` matching. One thing that is worth noting is that the input schema is different from the output one at `tMysqlRow` in the Job.

**Linking the components**

**Procedure**

1. Drop `tFixedFlowInput`, `tMysqlRow`, `tParseRecordSet` and `tLogRow` onto the workspace.
2. Rename `tFixedFlowInput` as `source_flow`, `tMysqlRow` as `insert_recordset`, `tParseRecordSet` as `parse_recordset` and `tLogRow` as `show_combined_flow`.
3. Link `tFixedFlowInput` to `tMysqlRow` using a `Row > Main` connection.
4. Link `tMysqlRow` to `tParseRecordSet` using a `Row > Main` connection.
5. Link `tParseRecordSet` to `tLogRow` using a `Row > Main` connection.

**Configuring the components**

**Procedure**

1. Double-click `tFixedFlowInput` to open its Basic settings view.
2. Select **Use Inline Content (delimited file)** in the **Mode** area.
   In the **Content** field, enter the data to be transferred:
   
   1;30
   2;20

3. Double-click the [...] button next to **Edit schema** to open the schema editor.

   Click the [+] button to add two columns, namely **id** and **age**, with the type of **Integer**.
   Click **Ok** to close the editor.

4. Double-click **tMysqlRow** to open its **Basic settings** view.
5. In the **Host** and **Port** fields, enter the connection details.
   In the **Database** field, enter the database name.
   In the **Username** and **Password** fields, enter the authentication details.
   In the **Query** field, enter the SQL query to retrieve the `id` and `name` data from the Mysql table `employee`: "select id, name from employee WHERE id=?".
   The question mark, "?", represents the parameter to be set in the **Advanced settings** tab.

6. Click the [...] button next to **Edit schema** to open the schema editor.

7. Click the [+] button to add two columns in the right part, namely `recordset` and `age`, with the type of **Object** and **Integer**. Note that `recordset` is intended to hold the query results of the Mysql table, namely the `id` and `name` fields.
   Click **OK** to close the editor.

8. Click the **Advanced settings** tab for further setup.
9. Select the Propagate QUERY's recordset check box and choose recordset from the use column list to insert the query results in that column.

Select the Use PreparedStatement check box and define the parameter used in the query in the Set PreparedStatement Parameters table.

10. Click on the [+ ] button to add a line.

In the Parameter Index cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.

In the Parameter Type cell, enter the type of parameter. Here, the parameter is an integer. Hence, select Int from the list.

In the Parameter Value cell, enter the parameter value. Here, we want to retrieve the id and name from the employee table based on the id value from the source flow. Hence, enter row3.id.

11. Double-click tParseRecordSet to open its Basic settings view.

12. Click the [...] button next to Edit schema to open the schema editor.
Click the [+] button to add three columns in the right part, namely id, name and age, with the type of Integer, String and Integer. Note that the id and name fields are intended to hold the parsed data of recordset.

Click OK to close the editor.

In the Attribute table, in the Value fields which correspond to id and name, enter the name of the column in the Mysql table to be retrieved, namely “id” and “name”.

13. Double-click tLogRow to open its Basic settings view.

In the Mode area, select Table (print values in cells of a table) for better display.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.

```
[statistics] connecting to socket on port 4030
[statistics] connected
+---------------------------------------------+
| show_combined_flow                       |

<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>Select the Mysql version you are using.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| Action on table | On the table defined, you can perform one of the following operations:  
- **None**: No operation is carried out.  
- **Create a table**: The table does not exist and gets created.  
- **Create a table if not exists**: The table is created if it does not exist. |
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| SCD Editor | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2537. |
| Use memory saving mode | Select this check box to maximize system performance. |
| Source keys include Null | Select this check box to allow the source key columns to have Null values. |
Warning:
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

### Advanced settings

**Additional JDBC Parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**End date time details**
Specify the time value of the SCD end date time setting in the format of **HH:mm:ss**. The default value for this field is **12:00:00**.
This field appears only when SCD Type 2 is used and **Fixed year value** is selected for creating the SCD end date.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

**Debug mode**
Select this check box to display each step during processing entries in a database.

### Global Variables

**Global Variables**

- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**
This component is used as Output component. It requires an Input component and Row main link as input.
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

This component does not support using SCD type 0 together with other SCD types.

SCD management methodology

Slowly Changing Dimensions (SCDs) are dimensions that change slowly over time.

The SCD editor offers the simplest method of building the data flow for the SCD outputs. In the SCD editor, you can map columns, select surrogate key columns, and set column change attributes through combining SCD types. The following figure illustrates an example of the SCD editor.
### SCD keys

You must choose one or more source keys columns from the incoming data to ensure its unicity.

You must set one surrogate key column in the dimension table and map it to an input column in the source table. The value of the surrogate key links a record in the source to a record in the dimension table. The editor uses this mapping to locate the record in the dimension table and to determine whether a record is new or changing. The surrogate key is typically the primary key in the source, but it can be an alternate key as long as it uniquely identifies a record and its value does not change.

**Source keys**: Drag one or more columns from the *Unused* panel to the *Source keys* panel to be used as the key(s) that ensure the unicity of the incoming data.

**Surrogate keys**: Set the column where the generated surrogate key will be stored. A surrogate key can be generated based on a method selected on the *Creation* list.

**Creation**: Select any of the below methods to be used for the key generation.

- **Auto increment**: auto-incremental key.
- **Input field**: key is provided in an input field.

When selected, you can drag the appropriate field from the *Unused* panel to the *complement* field.
• **Routine**: from the complement field, you can press Ctrl+Space to display the autocompletion list and select the appropriate routine.

• **Table max +1**: the maximum value from the SCD table is incremented to create a surrogate key.

• **DB Sequence**: from the complement field, you can enter the name of the existing database sequence that will automatically increment the column indicated in the name field.

Note that this option is only available through the SCD Editor of the tOracleSCD.

**Slowly Changing Dimensions types**

The Slowly Changing Dimensions support four types of changes: **Type 0** through **Type 3**. You can apply any of the SCD types to any column in a source table by a simple drag-and-drop operation.

• **Type 0**: is not used frequently. Some dimension data may be overwritten and other may stay unchanged over time. This is most appropriate when no effort has been made to deal with the changing dimension issues.

• **Type 1**: no history is kept in the database. New data overwrites old data. Use this type if tracking changes is not necessary. This is most appropriate when correcting certain typos, for example the spelling of a name.

• **Type 2**: the whole history is stored in the database. This type tracks historical data by inserting a new record in the dimensional table with a separate key each time a change is made. This is most appropriate to track updates, for example.

• **Type 3**: only the information about a previous value of a dimension is written into the database. This type tracks changes using separate columns. This is most appropriate to track only the previous value of a changing column.

SCD **Type 2** principle lies in the fact that a new record is added to the SCD table when changes are detected on the columns defined. Note that although several changes may be made to the same record on various columns defined as SCD **Type 2**, only one additional line tracks these changes in the SCD table.

The SCD schema in this type should include SCD-specific extra columns that hold standard log information such as:

• **start**: adds a column to your SCD schema to hold the start date. You can select one of the input schema columns as a start date in the SCD table.

• **end**: adds a column to your SCD schema to hold the end date value for a record. When the record is currently active, the end date is NULL or you can select Fixed Year Value and fill in a fictive year to avoid having a null value in the end date field.

Since the end column is used to identify the active record, you should set the Fixed year value parameter to the same value as the records that were created previously.

• **version**: adds a column to your SCD schema to hold the version number of the record.

• **active**: adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record.

**Tracking data changes using Slowly Changing Dimensions (type 0 through type 3)**

This scenario describes a Job that stores and manages both the current and historical employee data in a MySQL table using SCD (Slowly Changing Dimensions).
The input data contains various employee details including *name*, *age*, *role*, and *salary*, and another *id* column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new MySQL table using SCD:

```
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>age</th>
<th>role</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mark Smith</td>
<td>30</td>
<td>tester</td>
<td>11000.00</td>
</tr>
<tr>
<td>2</td>
<td>Thomas Johnson</td>
<td>32</td>
<td>developer</td>
<td>12000.00</td>
</tr>
<tr>
<td>3</td>
<td>Teddy Brown</td>
<td>33</td>
<td>tester</td>
<td>13000.00</td>
</tr>
</tbody>
</table>
```

Then the table is updated using SCD with the following renewed employee data.

```
<table>
<thead>
<tr>
<th>id</th>
<th>name</th>
<th>age</th>
<th>role</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mark Smith</td>
<td>31</td>
<td>tester</td>
<td>11000.00</td>
</tr>
<tr>
<td>2</td>
<td>Thomas Johnson</td>
<td>32</td>
<td>developer</td>
<td>12000.00</td>
</tr>
<tr>
<td>3</td>
<td>Teddy Brown</td>
<td>33</td>
<td>writer</td>
<td>13500.00</td>
</tr>
</tbody>
</table>
```

You can see the age of *Mark Smith* is updated from *30* to *31*, the role of *Teddy Brown* is changed from *tester* to *writer*, and his salary is raised from *13000.00* to *13500.00*. In this scenario,

- we don't want to track the data changes for the *name* field, so we will perform Type 0 SCD on it,
- we want the new *age* data to overwrite the existing data, so we will perform Type 1 SCD on it,
- we want to retain the full history of the *role* data, and always create a new record with the changed data and close the previous record, so we will perform Type 2 SCD on it,
- we want to keep the current and previous dimension values for the *salary* field, so we will perform Type 3 SCD on it.

For more information about SCD types, see [SCD management methodology](#) on page 2537.

**Creating a Job for tracking data changes in MySQL using SCD**

Create a Job to open a connection to a MySQL database, insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions)

This Job retrieves and displays the inserted data on the console, then updates the employee data in MySQL using SCD, retrieves and displays the updated data on the console, finally closes the connection to the MySQL database.
Procedure

1. Create a new Job and add a `tMysqlConnection` component, two `tFixedFlowInput` components, two `tMysqlSCD` components, two `tMysqlInput` components, two `tLogRow` components, and a `tMysqlClose` component by typing their names in the design workspace or dropping them from the Palette.

2. Link the first `tFixedFlowInput` component to the first `tMysqlSCD` component using a `Row > Main` connection.

3. Do the same to link the first `tMysqlInput` component to the first `tLogRow` component, the second `tFixedFlowInput` component to the second `tMysqlSCD` component, and the second `tMysqlInput` component to the second `tLogRow` component.

4. Link the `tMysqlConnection` component to the first `tFixedFlowInput` component using a `Trigger > OnSubJobOk` connection.

5. Do the same to link the first `tFixedFlowInput` component to the first `tMysqlInput` component, the first `tMysqlInput` component to the second `tFixedFlowInput` component, the second `tFixedFlowInput` component to the second `tMysqlInput` component, and the second `tMysqlInput` component to the `tMysqlClose` component.
Opening a connection to a MySQL database

Configure the tMysqlConnection component to open a connection to a MySQL database.

Procedure

1. Double-click the tMysqlConnection component to open its Basic settings view.

2. In the Host, Port, Database, Username, and Password fields, enter the information required for the connection to the MySQL database.

Inserting the employee data into a MySQL table using SCD

Configure the first tFixedFlowInput component and the first tMysqlSCD component to insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions).

Procedure

1. Double-click the first tFixedFlowInput component to open its Basic settings view.

2. Click the button next to Edit schema and in the pop-up window define the schema by adding five columns: id and age of Integer type, name and role of String type, and salary of Double type.
When done, click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

3. In the **Mode** area, select **Use Inline Content (delimited file)**. Then in the **Content** field displayed, enter the following input employee data.

```
1;Mark Smith;30;tester;11000.00
2;Thomas Johnson;32;developer;12000.00
3;Teddy Brown;33;tester;13000.00
```

4. Click the first **tMysqlSCD** component to open its **Basic settings** view.

5. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component you have configured.

6. In the **Table** field, enter the name of **employee_scd**.

7. Click the **button next to **SCD Editor** to open the SCD editor. All schema columns are listed on the **Unused** panel.

8. In the **name** field on the **Surrogate keys** panel, enter the name for the surrogate key, **SK** in this example.

9. From the **Unused** panel, drag and drop
   - **id** to the **Source keys** panel to use it as the key to ensure the unicity of the input data,
   - **name** to the **Type 0 fields** panel and no special action will be performed upon dimension changes of it,
• age to the **Type 1 fields** panel to perform Type 1 SCD on it,
• role to the **Type 2 fields** panel to perform Type 2 SCD on it, and
• salary to the **Type 3 fields** panel to perform Type 3 SCD on it.

10. In the **Versioning** panel, select the **version** check box to hold the version numbers for the historical and current records in the SCD table, and select also the **active** check box to add the column that will hold the **True** value for the current active record or the **False** value for the historical records in the SCD table.

   When done, click **OK** to save the changes and close the SCD editor.

**Retrieving the inserted employee data from MySQL**

Configure the first **tMysqlInput** component and the first **tLogRow** component to retrieve the inserted employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component you have configured.

3. In the **Table Name** field, enter the name of the table from which the employee data will be retrieved. In this example, it is `employee_scd`.

4. Open the schema editor of the **tMysqlSCD** component, select and copy all its schema columns, then open the schema editor of the **tMysqlInput** component, define its schema by pasting those schema columns you have copied from the **tMysqlSCD** component.

   When done, click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

5. Click the **Guess Query** button to fill the **Query** field with the automatically generated SQL query that will extract data of all columns from the specified table.
6. Double-click the first `tLogRow` component to open its Basic settings view. In the Mode area, select Table (print values in cells of a table) for better readability of the result displayed on the console.

**Updating the employee data in MySQL using SCD**

Configure the second `tFixedFlowInput` component and the second `tMysqlSCD` component to update the employee data in MySQL using SCD (Slowly Changing Dimensions).

**Procedure**

1. Double-click the second `tFixedFlowInput` component to open its Basic settings view.
2. Click the button next to Edit schema and in the pop-up window define the schema by copying and pasting the schema of the first `tFixedFlowInput` component.
3. In the Mode area, select Use Inline Content (delimited file). Then in the Content field displayed, enter the following updated employee data.

```
1;Mark Smith;31;tester;11000.00
2;Thomas Johnson;32;developer;12000.00
3;Teddy Brown;33;writer;13500.00
```

4. Repeat 4 on page 2543 through 10 on page 2544 in the procedure Inserting the employee data into a MySQL table using SCD on page 2542 to configure the second `tMysqlSCD` component.

**Retrieving the updated employee data from MySQL**

Configure the second `tMysqlInput` component and the second `tLogRow` component to retrieve the updated employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Repeat 1 on page 2544 through 5 on page 2545 in the procedure Retrieving the inserted employee data from MySQL on page 2544 to configure the second `tMysqlInput` component.
2. Repeat 6 on page 2546 in the procedure Retrieving the inserted employee data from MySQL on page 2544 to configure the second `tLogRow` component.

**Closing the connection to the MySQL database**

Configure the `tMysqlClose` component to close the connection to the MySQL database.

**Procedure**

1. Double-click the `tMysqlClose` component to open its Basic settings view.
2. From the Component List drop-down list, select the connection component that opens the connection you want to close. In this example, it is `tMysqlConnection_1`.

**Executing the Job to track data changes in MySQL using SCD**

After setting up the Job and configuring the components used in the Job for tracking data changes in MySQL using SCD, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press Ctrl + S to save the Job.
2. **Press F6 to execute the Job.**

As shown above, the new *age* data 31 for *Mark Smith* the old *age* data 30, a new record with the SK value set to 4 is created for the *role* change for *Teddy Brown* from *tester* to *writer*, and the values of the previous salary and the current salary for *Teddy Brown* are both kept in the newly created record.
**tMysqlSCDELT**

Reflects and tracks changes in a dedicated MySQL SCD table through SQL queries.

tMysqlSCDELT addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated MySQL SCD table.

**tMysqlSCDELT Standard properties**

These properties are used to configure tMysqlSCDELT running in the Standard Job framework.

The Standard tMysqlSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the Mysql version you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*. |
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>The IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication data for a dedicated database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Source table</strong></td>
<td>Name of the input MySQL SCD table.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | Select to perform one of the following operations on the table defined:  
- **None**: No action carried out on the table.  
- **Drop and create the table**: The table is removed and created again  
- **Create a table**: A new table gets created.  
- **Create a table if not exists**: A table gets created if it does not exist.  
- **Clear a table**: The table content is deleted. You have the possibility to rollback the operation.  
- **Truncate a table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
- **Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**.  
- **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see **Talend Studio User Guide**. |
<table>
<thead>
<tr>
<th><strong>Surrogate Key</strong></th>
<th>Select the surrogate key column from the list.</th>
</tr>
</thead>
</table>
| **Creation**      | Select the method to be used for the surrogate key generation.  
For more information regarding the creation methods, see SCD management methodology on page 2537. |
| **Source Keys**   | Select one or more columns to be used as keys, to ensure the unicity of incoming data. |
| **Use SCD Type 1 fields** | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes. |
| **Use SCD Type 2 fields** | Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes. |
| **SCD type 2 fields** | Click the button to add as many rows as needed, each row for a column. Click the arrow on the right side of the cell and select the column whose value changes will be tracked using Type 2 SCD from the drop-down list displayed.  
This table is available only when the Use SCD type 2 fields option is selected. |
| **Start date**    | Specify the column that holds the start date for type 2 SCD.  
This list is available only when the Use SCD type 2 fields option is selected. |
| **End date**      | Specify the column that holds the end date for type 2 SCD.  
This list is available only when the Use SCD type 2 fields option is selected. |
| **Log active status** | Select this check box and from the Active field drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD.  
This option is available only when the Use SCD type 2 fields option is selected. |
| **Log versions**  | Select this check box and from the Version field drop-down list displayed, select the column that holds the version number of the record for type 2 SCD.  
This option is available only when the Use SCD type 2 fields option is selected. |

**Advanced settings**

| **Debug mode** | Select this check box to display each step during processing entries in a database. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is used as an output component. It requires an input component and Row main link as input. |

Dynamic settings

| Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related Scenarios

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1874.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3060.
tMysqlSP

Calls a MySQL database stored procedure.

tMysqlSP offers a convenient way to centralize multiple or complex queries in a database and call them easily.

**tMysqlSP Standard properties**

These properties are used to configure tMysqlSP running in the Standard Job framework.

The Standard tMysqlSP component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

<td>only. Related topic: see <em>Talend Studio User Guide.</em></td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> You have already created the schema and stored it in the</td>
</tr>
<tr>
<td></td>
<td>Repository. You can reuse it in various projects and Job designs. Related</td>
</tr>
<tr>
<td></td>
<td>topic: see <em>Talend Studio User Guide.</em></td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>SP Name</th>
<th>Type in the exact name of the Stored Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Function / Return result in</td>
<td>Select this check box, if a value only is to be returned. Select on the list the schema column, the value to be returned is based on.</td>
</tr>
</tbody>
</table>
| Parameters | Click the Plus button and select the various **Schema Columns** that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure. Select the **Type** of parameter:

  - **IN**: Input parameter.
  - **OUT**: Output parameter/return value.
  - **IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).
  - **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value. |

**Note:**

Check **Inserting data in mother/daughter tables** on page 2452 if you want to analyze a set of records from a database table or DB query and return single records.

**Usage**

| Usage rule | This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic** |
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

The Stored Procedures syntax should match the Database syntax.

Using tMysqlSP to find a State Label using a stored procedure

The following job aims at finding the State labels matching the odd State IDs in a Mysql two-column table. A stored procedure is used to carry out this operation.

- Drag and drop the following components used in this example: tRowGenerator, tMysqlSP, tLogRow.
- Connect the components using the Row Main link.
- The tRowGenerator is used to generate the odd id number. Double-click on the component to launch the editor.

- Click on the Plus button to add a column to the schema to generate.
- Select the Key check box and define the Type to Int.
- The Length equals to 2 digits max.
• Use the preset function called **sequence** but customize the Parameters in the lower part of the window.

- Change the **Value** of step from 1 to 2 for this example, still starting from 1.
- Set the **Number of generated rows** to 25 in order for all the odd State id (of 50 states) to be generated.
- Click **OK** to validate the configuration.
- Then select the **tMysqlSP** component and define its properties.

• Set the **Property type** field to **Repository** and select the relevant entry on the list. The connection details get filled in automatically.
• Else, set manually the connection information.
• Click **Sync Column** to retrieve the generated schema from the preceding component.
Then click **Edit Schema** and add an extra column to hold the State Label to be output, in addition to the ID.

Type in the name of the procedure in the **SP Name** field as it is called in the Database. In this example, `getstate`. The procedure to be executed states as follows:

```sql
DROP PROCEDURE IF EXISTS `talend`.`getstate` $$
CREATE DEFINER=`root`@`localhost` PROCEDURE `getstate`(IN pid INT, OUT pstate VARCHAR(50))
BEGIN
  SELECT LabelState INTO pstate FROM us_states WHERE idState = pid;
END $$
```

In the **Parameters** area, click the plus button to add a line to the table.

Set the **Column** field to **ID**, and the **Type** field to **IN** as it will be given as input parameter to the procedure.

Add a second line and set the **Column** field to **State** and the **Type** to **Out** as this is the output parameter to be returned.

Eventually, set the **tLogRow** component properties.

Synchronize the schema with the preceding component.

And select the **Print values in cells of a table** check box for reading convenience.

Then save your Job and execute it.

The output shows the state labels corresponding to the odd state ids as defined in the procedure.
Note:
Check Inserting data in mother/daughter tables on page 2452 if you want to analyze a set of records from a database table or DB query and return single records.

Related scenarios

For related scenarios, see:

- Retrieving personal information using a stored procedure on page 2430.
- Checking number format using a stored procedure on page 2771.
- Executing a stored procedure using tMDMSP on page 2174.
tMysqlTableList

Lists the names of a given set of Mysql tables using a select statement based on a Where clause.
tMysqlTableList iterates on a set of table names through a defined Mysql connection.

**tMysqlTableList Standard properties**

These properties are used to configure tMysqlTableList running in the Standard Job framework.
The Standard tMysqlTableList component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the Where clause to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |
|-------------------------|-----------------------------------------------------------------

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>CURRENT_TABLE: the name of the table currently iterated upon. This is a Flow variable and it returns a string.</th>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Mysql components, especially with <strong>tMysqlConnection</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on <strong>Dynamic settings</strong> and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Iterating on DB tables and deleting their content using a user-defined SQL template

The following Java scenario creates a three-component job that iterates on given table names from a MySQL database using a WHERE clause. It then deletes the content of the tables directly on the DBMS using a user-defined SQL template.

For advanced use, start with creating a connection to the database that contains the tables you want to empty of their content.

- In the **Repository** tree view, expand **Metadata** and right click **DB Connections** to create a connection to the relevant database and to store the connection information locally.
  
  For more information about Metadata, see **Talend Studio User Guide**.

  Otherwise, drop a **tMySQLConnection** component in the design workspace and fill the connection details manually.

- Drop the database connection you created from the **Repository** onto the design workspace.

- The **Components** dialog box displays.

- Select **tMySQLConnection** and click **OK**.

  The **tMySQLConnection** components displays on the design workspace with all connection details automatically filled in its **Basic settings** view.

- Drop the following two components from the **Palette** onto the design workspace: **tMysqlTableList** and **tELT**.

- Connect **tMySQLConnection** to **tMysqlTableList** using an **OnSubjobOk** link.
Connect **tMysqlTableList** to **tELT** using an **Iterate** link.

If needed, double-click **tMysqlConnection** to display its **Basic settings** view and verify the connection details.

In this example, we want to connect to a MySQL database called **examples**.

In the design workspace, double-click **tMysqlTableList** to display its **Basic settings** view and define its settings.

On the **Component list**, select the relevant MySQL connection component if more than one connection is used.

Enter a **WHERE** clause using the right syntax in the corresponding field to iterate on the table name(s) you want to delete the content of.

In this scenario, we want the job to iterate on all the tables which names start with "ex".

In the design workspace, double-click **tELT** to display its **Basic settings** view and define its settings.
• In **Database Name**, enter the name of the database containing the tables you want to process.
• On the **Component list**, select the relevant MySQL connection component if more than one connection is used.
• Click in the **Table name** field and press **Ctrl+Space** to access the global variable list.
• From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))`.

**To create the user-defined SQL template:**

• In the **Repository** tree view, expand **SQL Templates** and **MySQL** in succession.

• Right-click **UserDefined** and select **Create SQLTemplate** from the drop-down list.

The **New SQLTemplate** wizard opens.
Enter a name for the new SQL template and fill in the other fields if needed and then click Finish to close the wizard.

An SQL pattern editor opens on the design workspace.

Delete the existing code and enter the code necessary to carry out the desired action, deleting the content of all tables which names start with "ex" in this example.

Note:
In the SQL template code, you must use the correct variable name attached to the table name parameter ("__TABLE_NAME__", in this example). To display the variable name used, put your pointer in the Table Name field in the basic settings of the tELT component.

Press Ctrl+S to save the new user-defined SQL template.

The next step is to add the new user-defined SQL template to the SQL template list in the tELT component.

To add the user-defined SQL template to the SQL template list:
• In the Component view of tELT, click the SQL Templates tab to display the SQLTemplate List.

![tELT_2](image)

• Click the Add button and add two SQL template lines.
• Click in the first line to display a drop-down arrow and then click the arrow to display the SQL template list.

![tELT_2](image)

• Select in the list the user-defined SQL template you already created.
• Make sure that the SQL template in the second line is Commit.
• Save your job and press F6 to execute it.

All tables in the MySQL examples database which names begin with "ex" are emptied from their content.

**Related scenario**

For tMysqlTableList related scenario, see Iterating on a DB table and listing its column names on page 2445.
tNamedPipeClose

Closes a named-pipe at the end of a process.
tNamedPipeClose closes a named-pipe opened with tNamedPipeOpen at the end of a process.

**tNamedPipeClose Standard properties**

These properties are used to configure tNamedPipeClose running in the Standard Job framework.
The Standard tNamedPipeClose component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

| Pipe | Select an existing named-pipe from the list to close. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is usually used to close a named-pipe at the end of a Job. |

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job.

When a dynamic parameter is defined, the Pipe box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic.
connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenario**

For a related scenario, see Writing and loading data through a named-pipe.
**tNamedPipeOpen**

Opens a named-pipe for writing data into it.

Used in inner-process communication, tNamedPipeOpen opens a named-pipe for writing data into it.

**tNamedPipeOpen Standard properties**

These properties are used to configure tNamedPipeOpen running in the Standard Job framework.

The Standard tNamedPipeOpen component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Name</th>
<th>Fill in the field with the name of the named-pipe.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete if already exist</td>
<td>Select this check box to avoid duplicate named-pipe.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

**Global Variables**

- **PIPE_NAME**: the name of the named-pipe. This is a Flow variable and it returns a string.
- **PIPE_NATIVE_NAME**: the native name of the named-pipe. This is a Flow variable and it returns a string.
- **PIPE_OUTPUTSTREAM**: the output stream of the named-pipe. This is a Flow variable and it returns an object.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

**Usage**

<p>| Usage rule | This component is usually used as the starting component in a inner-process communication Job. |</p>

</tr>
</tbody>
</table>

**Related scenario**

For a related scenario, see Writing and loading data through a named-pipe.
tNamedPipeOutput

 Writes data into an existing open named-pipe. 
 tNamedPipeOutput writes data into a named-pipe opened with tNamedPipeOpen.

**tNamedPipeOutput Standard properties**

These properties are used to configure tNamedPipeOutput running in the Standard Job framework. 
The Standard tNamedPipeOutput component belongs to the File family. 
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing pipe connection</strong></td>
<td>Select this check box to use an existing named-pipe in the Pipe component list, or clear this check box to specify a named-pipe in Pipe name field.</td>
</tr>
<tr>
<td><strong>Pipe component</strong></td>
<td>Select an existing named-pipe component from the list.</td>
</tr>
<tr>
<td><strong>Pipe name</strong></td>
<td>Fill in the field with the name of an existing named-pipe.</td>
</tr>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows in the output file.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields of the output file.</td>
</tr>
<tr>
<td><strong>CSV options</strong></td>
<td>Select this check box to take into account all parameters specific to CSV files, in particular Escape char and Text enclosure parameters.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. 

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

<table>
<thead>
<tr>
<th>Built-in: The schema will be created and stored locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</th>

</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is usually connected to another component in a subjob that reads data from a source.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job.

The **Dynamic settings** table is available only when the **Use existing pipe connection** check box is selected in the **Basic settings** view. When a dynamic parameter is defined, the **Pipe component** list box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
tNeo4jBatchOutput

Receives data from the preceding component and writes the data into a local Neo4j database.
tNeo4jBatchOutput is used to write nodes in a Neo4j database based on the defined index.

**tNeo4jBatchOutput Standard properties**

These properties are used to configure tNeo4jBatchOutput running in the Standard Job framework.
The Standard tNeo4jBatchOutput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **Use an existing connection** | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.
This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the **Remote server** check box in tNeo4jConnection.
Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. |
| **Database path** | Specify the directory to hold your data files. If the specified directory does not exist, it will be created.
This field appears only if you do not select the **Use an existing connection** check box. |
| **Shutdown after job** | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.
Alternatively, you can use tNeo4jClose to shutdown the database.
This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j.
This check box is available only if the **Use an existing connection** check box is not selected. |
| **Field that contains the label list** | Select the column from the input schema you have defined in the preceding components to provide labels for the nodes to be created.
When the input data provides multiple labels for a node, separate those labels by semi-colons (;) in the preceding components. |
| **Index name** | Enter, within double quotation marks, the name of the index to be created for the nodes. This index is used to store the identifiers of the nodes and help create relationships. |
Import identifier

Select the column from the input schema you have defined in the preceding components to provide identifiers for the nodes to be created. These identifiers are stored in the index to be created and must be unique cross the index. Therefore, ensure that the column to be used contains only unique values.

Save the identifier

Select this check box to save the technical identifiers (native graph ids).

For further information about the different types of Neo4j entity identifiers, see Neo4j documentation: Entity identifier.

Number of index elements in memory

Enter, without double quotation marks, the cache size used to keep the index elements in memory. This value must be enough to keep all of the index elements in memory.

For further information, see Neo4j documentation: Memory tuning.

Advanced settings

Neo4j configuration

Add parameters to the table to configure the database to be created.

For further information, see Neo4j documentation: Configuration settings.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component and it always needs an incoming link.</th>
</tr>
</thead>
</table>

tNeo4jBatchOutputRelationship

Receives data from the preceding component and writes relationships in bulk into a local Neo4j database.

**tNeo4jBatchOutputRelationship Standard properties**

These properties are used to configure tNeo4jBatchOutputRelationship running in the Standard Job framework.

The Standard tNeo4jBatchOutputRelationship component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Use existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection.  
Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. |
|-------------------------|--------------------------------------------------------------------------------------------------|
| Database path           | Specify the directory to hold your data files.  
This field appears only if you do not select the Use an existing connection check box. |
| Shutdown after job      | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.  
Alternatively, you can use tNeo4jClose to shutdown the database.  
This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j.  
This check box is available only if the Use an existing connection check box is not selected. |
| Field for relationship types | Select the column from the input schema you have defined in the preceding components to provide types for the relationships to be created. |
| Direction of the relationship | Select the direction of the relationships to be created:  
• Outgoing: The relationship starts from the start node to the end node.  
• Incoming: The relationship starts from the end node to the start node. |
Start node of the relationship

Defining the start node of each relationship using the node identifier:

- **Name of the batch index**: select the tNeo4jBatchOutput component used to create the start nodes. The name of the index for these nodes are retrieved from that component.
- **Field name for the batch index**: select the column from the input schema you have defined in the preceding components to provide the name of the start node of each relationship to be created.

End node of the relationship

Defining the end node of each relationship using the node identifier:

- **Name of the batch index**: select the tNeo4jBatchOutput component used to create the end nodes. The name of the index for these nodes are retrieved from that component.
- **Field name for the batch index**: select the column from the input schema you have defined in the preceding components to provide the name of the end node of each relationship to be created.

Die on error

Select the check box to stop the execution of the Job when an error occurs.
Clear the check box to skip any rows on error and complete the process for error-free rows.

Advanced settings

Neo4j configuration

Add parameters to the table to configure the database to be created.

For further information, see Neo4j documentation: Configuration settings.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

Global Variables

**Global Variables**

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th></th>

Writing information of actors and movies to Neo4j with hierarchical relationship using Neo4j Batch components

In this scenario, Neo4j Batch components are used to import data about actors and movies from two CSV files in a local Neo4j database and create relationship for the data based on another CSV file that describes the actors' roles in the movies.

This scenario applies only to Talend products with Big Data.

The Neo4j Batch components provided by Talend supports bulk writing to a local Neo4j database only. They can be used neither with Neo4j versions prior to V3.2.X nor alongside Neo4j components that are using one of those Neo4j versions.

The components to be used are:

- One tNeo4jConnection component: it opens the connection to Neo4j to be reused.
- Three tFileInputDelimited components: they read the input information of actors and movies.
- Two tNeo4jBatchOutput components: they write information of movies and actors to the connected Neo4j database.
- One tNeo4jBatchOutputRelationship component: it creates relationship between actors and movies.
- One tNeo4jBatchSchema component: it creates an uniqueness constraint on the nodes in the database.
Creating the Neo4j Batch Job

Procedure

1. Ensure that the status of your Neo4j service and Neo4j console is stop.
   If you are using command-line to manage Neo4j, you can use `neo4j status` to check the status; if you have installed the Neo4j desktop application, you can check it directly in this application.

2. From the Repository on the Integration perspective, create a Job and add the components to be used by typing their names in the design workspace or dropping them from the Palette.

3. Connect the first `tFileInputDelimited` component to the first `tNeo4jBatchOutput` component using a Row > Main link. This subJob imports the actors data in the Neo4j database.

4. Connect the second `tFileInputDelimited` component to the second `tNeo4jBatchOutput` component using a Row > Main link. This subJob imports the movies data in the Neo4j database.

5. Connect the third `tFileInputDelimited` component to the `tNeo4jBatchOutputRelationship` component using a Row > Main link. This subJob creates relationship between actors and movies.

6. Connect the subJobs using Trigger > On Subjob Ok links.

Configuring the Neo4j connection to be reused

Procedure

1. Double-click the `tNeo4jConnection` component to open its Basic settings view.
2. From the DB Version list, select Neo4J 3.2.X.
3. Ensure that the Use a remote server check box is clear because that the Neo4j Batch components work only on the local mode.
4. In the Database path field, enter the path or browse to the database file.

**Bulk-writing the actors data in Neo4j**

**Procedure**

1. Double-click the first tFileInputDelimited component to open its Component view.

2. In the File name/Stream field, enter the path or browse to the CSV file that describes the actors' IDs, names and their labels to be used in Neo4j.

   The input CSV file used in this example reads as follows:
   ```
   keanu,"Keanu Reeves",Actor
   laurence,"Laurence Fishburne",Actor
   carrieanne,"Carrie-Anne Moss",Actor
   ```

   The double quotation marks on the actor names are not mandatory.

3. Click the [...] button next to Edit schema to open the schema editor, and define the input schema based on the structure of the input file.

   In this example, the columns are id, name and label, all of type String.
4. Click **OK** to close this editor and accept the propagation of the schema to the next component.

5. In the **Field separator** field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the first **tNeo4jBatchOutput** component to open its **Component** view.

7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field that contains the label list** drop-down list, select the column that provides labels.

10. In the **Index name** field, enter the name of the index to be created for the nodes.

11. From **Import identifier** drop-down list, select the column that provides IDs.

---

**Bulk-writing the movies data into Neo4j**

**Procedure**

1. Double-click the second **tFileInputDelimited** component to open its **Component** view.
2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the movies' IDs, names, release years and their labels to be used in Neo4j.

The input CSV file used in this example reads as follows:

```
tt0133093,"The Matrix",1999,Movie
tt0234215,"The Matrix Reloaded",2003,Movie;Sequel
tt0242653,"The Matrix Revolutions",2003,Movie;Sequel
```

The double quotation marks on the movie names are not mandate.

3. Click the [...] button next to **Edit schema** to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are **id**, **title**, **released** and **label**.

4. Click **OK** to close this editor and accept the propagation of the schema to the next component.

5. In the **Field separator** field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the second **tNeo4jBatchOutput** component to open its **Component** view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field that contains the label list** drop-down list, select the column that provides labels.

10. In the **Index name** field, enter the name of the index to be created for the nodes.

11. From **Import identifier** drop-down list, select the column that provides IDs.

## Creating relationships in bulk

### Procedure

1. Double-click the third **tFileInputDelimited** component to open its **Component** view.

2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the actor-movie relationships.
The input CSV file used in this example reads as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Role</th>
<th>Movie ID</th>
<th>Relationship Type</th>
</tr>
</thead>
<tbody>
<tr>
<td>keanu</td>
<td>Neo</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>keanu</td>
<td>Neo</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>keanu</td>
<td>Neo</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>Morpheus</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>Morpheus</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>Trinity</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>Trinity</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>Trinity</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
</tbody>
</table>

The double quotation marks on the role names are not mandatory. The value ACTED_IN is an user-defined relationship type that explains the relationship between the actors and the movies.

3. Click the [...] button next to Edit schema to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are from, role, to and type.

4. Click OK to close this editor and accept the propagation of the schema to the next component.

5. In the Field separator field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the tNeo4jBatchOutputRelationship component to open its Component view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field for relationship type** drop-down list, select the column that provides the relationship types.

10. From the **Direction of the relationship** drop-down list, select **Outgoing**.

11. In the **Start node of the relationship** area, select the tNeo4jBatchOutput component that provides the index of the start nodes, which is the `asActors` index in this example from the first tNeo4jBatchOutput. Then from the **Field name for the batch index** drop-down list, select the column that provides the actor names as the start nodes.

12. Repeat this action in the **End node of the relationship** area to select the `asMovie` index from the second tNeo4jBatchOutput and then select the column that provides the movie names as the end nodes.

**Adding uniqueness constraints on the nodes**

**Procedure**

1. Double-click the tNeo4jBatchSchema component to open its **Component** view.
2. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

3. Select the **Shutdown after Job** check box to properly close the connection after the execution.

4. In the **Schema definition** table, add two rows by clicking the [*] button twice:
   a) In the **Schema type** column, select **Node property is unique** for both of the rows to add uniqueness constraints to nodes in Neo4j.
   b) In the **For node with Label** column, enter, within double quotation marks, `Actor` and `Movie` respectively, which are the labels used by the actor nodes and the movie nodes. Therefore, what you enter here must be identical with the labels previously used when creating those nodes.
   c) In the **On property** column, enter, within double quotation marks, the node properties to which you need to add uniqueness constraints. For the actor nodes, enter `name` and for the movie nodes, enter `title`. The values you enter here must be identical with the column names previously defined to provide actor names and movie names for the nodes to be created by the tNeo4jBatchOutput components.

5. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to execute the Job.

**Results**

Once the Job runs successfully to the end, check the result in your Neo4j browser:
### tNeo4jBatchSchema

Defines the schema of a local Neo4j database.

### tNeo4jBatchSchema Standard properties

These properties are used to configure tNeo4jBatchSchema running in the Standard Job framework.

The Standard tNeo4jBatchSchema component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

#### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.</td>
</tr>
<tr>
<td><strong>Database path</strong></td>
<td>Specify the directory to hold your data files. If the specified directory does not exist, it will be created. This field appears only if you do not select the Use an existing connection check box.</td>
</tr>
<tr>
<td><strong>Shutdown after job</strong></td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as 'Id file not properly shutdown' at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected.</td>
</tr>
</tbody>
</table>
| **Schema definition**             | Add indexes and unique property constraints to define the schema:  
  - **Schema type**: select whether it is an index (Index on node property) or a constraint (Node property is unique) to be defined.  
  - **For node with label**: enter, within double quotation marks, the label of a node.  
  - **On property**: enter, within double quotation marks, the property of a node. |
**Advanced settings**

| **Neo4j configuration** | Add parameters to the table to configure the database to be created.  
For further information, see Neo4j documentation:  
Configuration settings.  
When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

| **Global Variables** | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
|-----------------------|---------------------------------------------------------------------------------------------------------------------------|

**Usage**

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is used standalone in a subjob to write a Neo4j graph schema.</th>
</tr>
</thead>
</table>
tNeo4jClose

Close an active connection to an Neo4j database in embedded mode.

**tNeo4jClose Standard properties**

These properties are used to configure tNeo4jClose running in the Standard Job framework.

The Standard tNeo4jClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Connection | Select an active Neo4j database connection to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | This component is to be used along with other Neo4j components, especially with **tNeo4jConnection**. |

| Limitation | n/a |

**Related scenarios**

For scenario in which **tNeo4jClose** is used, see:

- Writing information of actors and movies to Neo4j with hierarchical relationship on page 2615,
• Creating nodes with a label using a Cypher query on page 2628, and
• Importing data from a CSV file to Neo4j using a Cypher query on page 2632.
tNeo4jConnection

Opens a connection to a Neo4j database to be reused by other Neo4j components.
tNeo4jConnection starts the database in embedded mode, and checks the server availability in REST mode.

**tNeo4jConnection Standard properties**

These properties are used to configure tNeo4jConnection running in the Standard Job framework.
The Standard tNeo4jConnection component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **DB version** | Select the Neo4j version you are using.  
When you use V3.2.X:  
• If you work with a remote server, only tNeo4jInput and tNeo4jRow can reuse the connection defined in tNeo4jConnection because these components work with Neo4j remote servers only.  
• If you work with a local server, only tNeo4jBatchOutput, tNeo4jBatchSchema and tNeo4jBatchOutput putRelationship can reuse the connection defined in tNeo4jConnection because these components work with Neo4j local servers only.  
Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.  
Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.  
Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in the Talend Help Center (https://help.talend.com). |
| **Remote server** | Select this check box if you use a Neo4j remote server, and specify the root URL in the **Server URL** field.  
• **Set username**: this check box is available when you have selected the **Use a remote server** check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
• **Username** and **Password**: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required. |
| **Server URL** | Specify the root URL. |
This field is available only if the Use a remote server check box is selected.

Read only
Select this check box if you want to use the embedded database in read only mode. It's useful if an application is already dedicated with the database.
This check box is available only when you are using a 2.X.X version.

**Warning:**
Do not use this mode when you have any output Neo4j component in your Job such as `tNeo4jOutput`, `tNeo4jOutputRelationship` or `tNeo4jRow`.

Database path
If you use Neo4j in embedded mode, specify the path of data file.
This field is available only if the Use a remote server check box is not selected.

Advanced settings

**tStatCatcher Statistics**
Select this check box to collect the log data at a component level.

Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**
This component is generally used with other Neo4j components, particularly `tNeo4jClose`.

**Limitation**

n/a

Related scenarios

For scenario in which `tNeo4jConnection` is used, see:

</thead>
</table>
| **Neo4j configuration** | Add parameters to the table to configure the database to be created.  
For further information, see Neo4j documentation: Configuration settings.  
When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table. |
| **Import configuration** | Add parameters to the table to configure Neo4j Import Tool. |
For further information, see Neo4j documentation: Import Tool usage.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

## Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

## Usage

| Usage rule | This component is to be used standalone in a subjob to load data in bulk from given CSV files that have been created with specific structure. For further information about the CSV structure required by Neo4j Import Tool, see Import. You can use tFileOutputDelimited to create the CSV files to be used. If so, bear the following configuration in mind: • Line separator: "\n" • Field separator: "," • Do not include headers. • File encoding: UTF-8. |
tNeo4jInput

Reads data from Neo4j and sends data in the output Talend flow.

`tNeo4jInput` reads data from Neo4j based on Cypher query allowing any further transformation or processing of the data in the rest of the Job.

**tNeo4jInput Standard properties**

These properties are used to configure `tNeo4jInput` running in the Standard Job framework.

The Standard `tNeo4jInput` component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>DB version</strong></td>
<td>Select the Neo4j version you are using. When you are using Neo4j version 3.2.X, this component works in the remote mode only. Therefore, if you want to reuse a connection to Neo4j V3.2.X from <code>tNeo4jConnection</code>, ensure that you have selected the <strong>Remote server</strong> check box and properly configured the connection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels. This list is not shown if the <strong>Use an existing connection</strong> check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td><strong>Shutdown after job</strong></td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use <code>tNeo4jClose</code> to shutdown the database. This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j. This check box is available only if the <strong>Use an existing connection</strong> check box is not selected.</td>
</tr>
<tr>
<td><strong>Remote server</strong></td>
<td>Select this check box if you use a Neo4j remote server, and specify the root URL in the <strong>Server URL</strong> field.</td>
</tr>
</tbody>
</table>
- **Set username:** this check box is available when you have selected the **Use a remote server** check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.
- **Username** and **Password:** enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.

This check box appears only if you do not select the **Use an existing connection** check box and you are not using Neo4j V3.2.X. With V3.2.X, this component supports the remote mode only.

### Database path
If you use Neo4j in embedded mode, specify the path of data file.

This field appears only if you do not select the **Use an existing connection** check box or the **Remote server** check box.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Query
Enter your Cypher query in double quotes, with return parameters matching the mapping table.

### Mapping
Complete this table to specify the column or columns to be extracted and the corresponding column family or families. The **Column** fields of this table are automatically filled once you have defined the schema; fill the **Return parameter** fields with return parameters to map the node properties in the Cypher query with the schema columns.

Be sure to enclose your return parameters in double quotes.

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
|                  | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
|                  | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
|                  | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component always needs an output link. |
| Limitation | n/a |

Related scenarios

For a related scenario, see Writing data to a Neo4j database and reading specific data from it on page 2602.
tNeo4jOutput

Receives data from the preceding component and writes the data into Neo4j.

*tNeo4jOutput* is used to write data into a Neo4j database, and/or update or delete entries in the database based on the index defined.

**tNeo4jOutput Standard properties**

These properties are used to configure *tNeo4jOutput* running in the Standard Job framework.

The Standard *tNeo4jOutput* component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

<tr>
<td></td>
<td>• <strong>Username</strong> and <strong>Password</strong>: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.</td>
</tr>
<tr>
<td></td>
<td>This check box appears only if you do not select the <strong>Use an existing connection</strong> check box.</td>
</tr>
</tbody>
</table>
| Database path | If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created.  
This field appears only if you do not select the **Use an existing connection** check box or the **Remote server** check box. |
| --- | --- |
| Shutdown after job | Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.  
Alternatively, you can use tNeo4jClose to shutdown the database.  
This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j.  
This check box is available only if the **Use an existing connection** check box is not selected. |
| Mapping | Click the [...] button or double-click the component on the design workspace to open the indexes and relationships mapping editor. Use it to index node or create relationships during the node insertion.  
- **Select the Auto indexed check box** for a column to automatically index nodes with this property.  
- **Index creation**: With a column selected, click the [+ ] button to create as many indexes as you want on nodes with the property corresponding to the selected column.  
  - **Name**: Specify an index name in double quotes.  
  - **Key**: Specify an index key in double quotes.  
  - **Value (empty for current row)**: Specify an index value in double quotes. If you leave this field empty, the default value of the index added on each node will be the value of this property of the current node.  
  - **Unique**: Select this check box if you want the defined index to be created only once within the graph, rather than on each node.  
- **Relationship creation**: With a column selected, click the [+ ] button to create as many relationships as you want for nodes with the property corresponding to the selected column.  
  - **Type**: Specify a relationship type in double quotes.  
  - **Direction**: Select a relationship direction, between **Outgoing** and **Incoming**.  
  - **Index name**: Specify an index name for the relationship, in double quotes.  
  - **Index key**: Specify an index key for the relationship, in double quotes.  
  - **Value (empty for current row)**: Specify an index value for the relationship, in double quotes. If you leave this field empty, the default value of the index added on the relationship will be the value of this property of the current node. |
| Use label (Neo4j > 2.0) | Select this check box to create nodes with a label. Enter your label name in the **Label name** field. |
This check box is not shown if Neo4j 1.X.X is selected from the DB Version list or Delete is selected from the Data action list.

Note that this option works only with Neo4j 2.0 onwards and Java 7.

<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Writing data to a Neo4j database and reading specific data from it**

This scenario applies only to *Talend products with Big Data*.

This basic scenario describes a Job composed of two subJobs: the first subJob reads employees data from a CSV file and writes it to a Neo4j database, and then triggers the second subJob, which reads the employees data based on certain query conditions from the Neo4j database and displays the data on the **Run** console.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
   - a **tFileInputDelimited** component, to read the employees data from a CSV file,
   - a **tNeo4jOutput** component to write the employees data to a Neo4j database,
   - a **tNeo4jInput** component to read the employees data from the Neo4j database based on given conditions, and
   - a **tLogRow** component to display the data on the **Run** console.

2. Link the **tFileInputDelimited** component to the **tNeo4jOutput** component using a **Row > Main** connection.

3. Link the **tNeo4jInput** component to the **tLogRow** component using a **Row > Main** connection.

4. Link the **tFileInputDelimited** component to the **tNeo4jInput** component using a **Trigger > On Subjob Ok** connection.

5. Label the components to better identify their roles in the Job.
Configuring the components

Importing data to the Neo4j database

Procedure

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the **Components** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the employees data to read.

   The input CSV file used in this example is as follows:

   ```
   employeeID;employeeName;age;hireDate;salary;managerID
   1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
   2;Warren Adams;43;05-22-2008;11626.68;m6
   3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
   4;Herbert Quincy;54;06-14-2007;10694.71;m6
   5;Woodrow Polk;33;08-14-2007;13751.50;m4
   6;Theodore Johnson;47;01-26-2008;12426.87;m6
   7;Benjamin Adams;32;02-25-2008;10438.65;m4
   8;Woodrow Harrison;51;10-11-2008;11188.27;m5
   9;George Truman;40;04-28-2008;14254.49;m5
   10;Harry Jackson;38;04-01-2008;12798.78;m6
   ```
3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: `employeeID` (integer), `employeeName` (String), `age` (Integer), `hireDate` (Date), `salary` (Float), and `managerID` (String).

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

![Schema dialog box](image)

5. Click the **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

![Basic settings](image)

6. Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.

7. If needed, click the **Sync columns** button to ensure the component has the same schema as the preceding component.

   Keep the rest of the parameters as they are.
Reading data from the Neo4j database

Procedure

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

2. As in the **tNeo4jOutput** component, specify the URL of the Neo4j server to connect to, "http://localhost:7474/db/data" in this example.

3. Click the [...] button next to **Edit schema** and define the schema for employees information display. When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

The defined schema columns automatically appear in the **Mapping** table.
4. In the **Query** field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find employees who are more than 40 years old and are under the manager `m6`.

   "MATCH (n) WHERE n.age > 40 AND n.managerID = 'm6' RETURN n;"

5. Fill the **Return parameter** field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the **tLogRow** component to open its **Basic settings** view, and select the **Table (print values in cells of a table)** option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

The employees data of the CSV file is written to the Neo4j database and then the information of employees matching the set conditions is retrieved from the Neo4j database and displayed on the console.

**Writing family information to Neo4j and creating relationships**

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that will write family information to labeled nodes in a remote Neo4j database and create relationships based on the family names.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
   - A **tFileInputDelimited** component, to read the family data from a CSV file,
• a **tNeo4jOutput** component to write the family data to a Neo4j database and create relationships between husband and wife.

2. Link the **tFileInputDelimited** component to the **tNeo4jOutput** component using a **Row > Main** connection.

3. Label the components to better identify their roles in the Job.

---

### Configuring the components

#### Configuring the data source

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the **Components** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the family data to read.

   The input CSV file used in this example is as follows:

   ```
   Name,Gender,Age,Family
   Jenny,Female,24, the Johnsons
   Jack,Male,26, the Johnsons
   Richard,Male,35, the Blacks
   Anne,Female,36, the Whites
   Helen,Female,28, the Blacks
   Tom,Male,38, the Whites
   ```

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: **name** (integer), **gender** (String), **age** (Integer), and **family** (String).
When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

**Writing data to Neo4j and creating indexes and relationships**

**Procedure**

1. Click the **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

2. From the **DB Version** list, select **Neo4J 2.X.X** to enable node labeling.

3. Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.
4. Double-click the `tNeo4jOutput` component or click the Mapping button on the component’s Basic settings view to open the index and relationship mapping editor.

5. With the `name` column selected from the schema panel, click the Index creation tab, click the `[+]` button to add a row in the table, and create an index named `first_name` on this column:
   - In the Name field, enter `first_name` between double quotation marks.
   - In the Key field, enter `first_name` between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation.

6. With the `family` column selected from the schema panel, click the Index creation tab, click the `[+]` button to add a row in the table, and create an index named `family` on this column:
   - In the Name field, enter `family` between double quotation marks.
   - In the Key field, enter `family_name` between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation.

7. With the `family` column selected from the schema panel, click the Relationship creation tab, click the `[+]` button to add a row in the table, and create a relationship named `Spouse` on this column based on the index named `family`:
   - In the Type field, enter `Spouse` between double quotation marks.
   - From the Direction list field, select either Outgoing or Incoming.
   - In the Index Name field, enter `family` between double quotation marks.
   - In the Index Key field, enter `family_name` between double quotation marks.

Then click in the schema panel to validate your relationship creation, and click OK to close the mapping editor.
8. Select the **Use label (Neo4j > 2.0)** check box and enter *Families* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Families*.

9. From the **Data action** list, select **Insert or update**, and set a reference key in the **Index** area that appears:
   - In **Index name** field, enter *first_name* between double quotation marks.
   - In **Index key** field, enter *first_name* between double quotation marks.
   - From **Index value** field, select *name*. As the **Value** field is left blank in index creation, the index value will be the value of the *name* column for each row.

This way, when the Job is executed, nodes will be inserted or updated in the Neo4j database based on the *first_name* index: for each data row, if a node containing the same first name already exists in the database, the node will be updated; otherwise, a new node will be created.

**Executing the Job and checking the result**

**Procedure**

1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.
2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, [http://localhost:7474/](http://localhost:7474/) in this example, and enter the following Cypher query in the command line to view the nodes.

   ```cypher
   MATCH (n:`Families`) RETURN n;
   ```

   As shown in the graphic view, three pairs of nodes labeled *Families* have been created and those with the same family name are linked together via the relationship *Spouse*. 
tNeo4jOutputRelationship

Receives data from the preceding component and writes relationships into Neo4j.

**tNeo4jOutputRelationship Standard properties**

These properties are used to configure tNeo4jOutputRelationship running in the Standard Job framework.

The Standard tNeo4jOutputRelationship component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB version</td>
<td>Select the Neo4j version you are using. This component does not support Neo4j version V3.2.X. Do not reuse the connection to V3.2.X defined in a tNeo4jConnection component. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels. This list is not shown if the Use an existing connection check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td>Remote server</td>
<td>Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field. • Set username: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear. • Username and Password: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required. This check box appears only if you do not select the Use an existing connection check box.</td>

<td>Specify the index key to query the starting node.</td>
</tr>
</tbody>
</table>
### Start node / Index value
Select the index value to query the starting node.

### Relationship direction
Select a relationship direction.
- **Outgoing**: The relationship starts from the start node to the end node.
- **Incoming**: The relationship starts from the end node to the start node.

### End node / Index name
Specify the index name to query the ending node of the newest relationship.

### End node / Index key
Specify the index key to query the ending node.

### End node / Index value
Select the index value to query the ending node.

### Mapping
Use this table to map relationship properties with the input schema columns.

### Advanced settings

#### Commit every
Enter the number of rows to be completed before committing batches of nodes together the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

This option is only supported by the embedded mode of the database. You can’t make transactions in REST mode.

#### Batch import
Select this check to activate the batch mode

This option is only supported by the embedded mode of the database. **Be very careful with the batch import mode. Because this option is unsafe, perform a backup before Job execution.**

If you want more explanations about memory mapping configuration of batch import, please refer to Neo4j documentation at: [http://neo4j.com/docs/stable/batchinsert-examples.html](http://neo4j.com/docs/stable/batchinsert-examples.html)

#### Node store mapped memory
Type in the memory size in MB allocated to nodes.

#### Relationship store mapped memory
Type in the memory size in MB allocated to relationships.

#### Property store mapped memory
Type in the memory size in MB allocated to property.

#### String store mapped memory
Type in the memory size in MB in Mo allocated to strings.

#### Array store mapped memory
Type in the memory size in MB allocated to arrays.

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
**tNeo4jOutputRelationship**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

---

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component and it always needs an incoming link.</th>

<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### Writing information of actors and movies to Neo4j with hierarchical relationship

This scenario applies only to [Talend products with Big Data](#).

This scenario describes a Job that will import information about actors and movies from two CSV files into a remote Neo4j database and then create relationship between the actors and the movies based on another CSV file that describes the actors’ roles in the movies.

### Adding and linking components

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a **tNeo4jConnection** component, to open a connection to a Neo4j database,
   - three **tFileInputDelimited** components, to read the input information of actors and movies,
   - two **tNeo4jOutput** components, to write information of movies and actors to the connected Neo4j database,
   - a **tNeo4jOutputRelationship** component, to create relationship between actors and movies, and
   - a **tNeo4jClose** component, to close the previous opened Neo4j connection at the end of Job execution.

2. Link the first **tFileInputDelimited** to the first **tNeo4jOutput** component using a **Row > Main** connection. This subJob will import the actors data into the Neo4j database.

3. Link the second **tFileInputDelimited** component to the second **tNeo4jOutput** component using a **Row > Main** connection. This subJob will import the movies data into the Neo4j database.

4. Link the third **tFileInputDelimited** component to the **tNeo4jOutputRelationship** component using a **Row > Main** connection. This subJob will create relationship between actors and movies.
5. Link the subjobs using **Trigger > On Subjob Ok** connections.
6. Label the components to better identify their roles in the Job.

---

**Configuring the components**

**Opening a Neo4j database connection**

**Procedure**

1. Double-click the **tNeo4jConnection** component to open its **Basic settings** view on the **Component** tab.
2. From the **DB Version** list, select **Neo4J 2.X.X** to enable node labeling.

3. Select the **Use a remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.

### Importing the actors data into Neo4j

**Procedure**

1. Double-click the first **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that describes the actors’ names, the years they were born in, and their roles in the movies.

   The input CSV file used in this example is as follows:

   ```
   Name;Born
   Keanu Reeves;1964
   Laurence Fishburne;1961
   Carrie-Anne Moss;1967
   ```

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of two columns, **name** and **born**, both of type String.

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
5. Click the first **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. Double-click the **tNeo4jOutput** component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

8. With the **name** column selected from the schema panel, click the **Index creation** tab, click the **[+]** button to add a row in the table, and create an index named **name** on this column:
   - In the **Name** field, enter **name** between double quotation marks.
   - In the **Key** field, enter **name** between double quotation marks to give the index a key **name**.

   Then click in the schema panel to validate your index creation, and click **OK** to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Actors* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Actors*.

**Importing the movies data into Neo4j**

**Procedure**

1. Double-click the second **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the information of the movies.
The input CSV file used in this example is as follows:

<table>
<thead>
<tr>
<th>Title</th>
<th>Released</th>
<th>Tagline</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Matrix</td>
<td>03-31-1999</td>
<td>Welcome to the Real World</td>
</tr>
<tr>
<td>The Matrix Reloaded</td>
<td>05-07-2003</td>
<td>Free Your Mind</td>
</tr>
<tr>
<td>The Matrix Revolutions</td>
<td>10-27-2003</td>
<td>Everything that has a Beginning has an End</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, **title** (type String), **released** (type Date), and **tagline** (type String). When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

5. Click the second **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. Double-click the **tNeo4jOutput** component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

8. With the **title** column selected from the schema panel, click the **Index creation** tab, click the [+] button to add a row in the table, and create an index named **title** on this column:
   - In the **Name** field, enter **title** between double quotation marks.
   - In the **Key** field, enter **title** between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation, and click **OK** to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Movies* between double quotation marks in the Label name field so that the nodes to be created will be labeled *Movies*.

Creating actor-movie relationship in Neo4j

Procedure

1. Double-click the third **tFileInputDelimited** component to open its **Basic settings** view on the Component tab.

2. In the File name/Stream field, specify the path to the CSV file that describes the actors' roles in the movies.
The input CSV file used in this example is as follows:

<table>
<thead>
<tr>
<th>Actor</th>
<th>Movie</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix</td>
<td>Neo</td>
</tr>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix Reloaded</td>
<td>Neo</td>
</tr>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix Revolutions</td>
<td>Neo</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>The Matrix</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>The Matrix Reloaded</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>The Matrix Revolutions</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix</td>
<td>Trinity</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix Reloaded</td>
<td>Trinity</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix Revolutions</td>
<td>Trinity</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, *actor*, *movie*, and *role*, all of type String.
   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

5. Double-click the **tNeo4jOutputRelationship** component to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Relationship type** field, enter the type of relationship to be created, between double quotation marks. In this example, the relationship type is *ACTED_IN*, which will appear as the label of the relationship between nodes.

8. Define the start and end nodes and the direction of the relationship to be created. In this example, the relationship will be created from *Actors* nodes, on which an index called *name* has been defined, to *Movies* nodes, on which an index called *title* has been defined.
• **Start node**: enter *name* between double quotation marks in the **Index name** and **Index key** fields, and select the schema column *name* from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column *name* for each row.

• From the **Relationship direction** list, select **Outgoing**.

• **End node**: enter *title* between double quotation marks in the **Index name** and **Index key** fields, and select the schema column *title* from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column *title* for each row.

9. Click the [+<br> button three times to add three rows in the **Mapping** table to define three properties of the relationship:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value taken from...</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Actor</strong></td>
<td>actor column of the schema</td>
</tr>
<tr>
<td><strong>Movie</strong></td>
<td>movie column of the schema</td>
</tr>
<tr>
<td><strong>Role</strong></td>
<td>role column of the schema</td>
</tr>
</tbody>
</table>

### Executing the Job and checking the result

**Procedure**

1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.

2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, http://localhost:7474/ in this example, and enter the following Cypher query in the command line to view the nodes with the specified relationship between them.

   ```cypher
   MATCH (a)-[:`ACTED_IN`]->(b) RETURN a,b;
   ```

As shown in the graphic view, **Actors** nodes are linked with **Movies** nodes via the relationship **ACTED_IN**, with properties as defined in the Job.
**tNeo4jRow**

Executes the stated Cypher query onto the specified Neo4J database.
Depending on the nature of the query, tNeo4jRow acts on the data (although without handling data).
tNeo4jRow is the specific component for Neo4J database query. It implements a flow in the Job design although it doesn’t provide output.

**tNeo4jRow Standard properties**

These properties are used to configure tNeo4jRow running in the Standard Job framework.
The Standard tNeo4jRow component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB version</td>
<td>Select the Neo4j version you are using. When you are using Neo4j version 3.2.X, this component works in the remote mode only. Therefore, if you want to reuse a connection to Neo4j V3.2.X from tNeo4jConnection, ensure that you have selected the Remote server check box and properly configured the connection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels. This list is not shown if the Use an existing connection check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>
| Remote server              | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.  
  * Set username: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
  * Username and Password: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required. |
### Database path

If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created.

This field appears only if you do not select the **Use an existing connection** check box or the **Remote server** check box.

### Shutdown after job

Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.

Alternatively, you can use tNeo4jClose to shutdown the database.

This avoids errors such as 'Id file not properly shutdown' at next execution of Jobs involving Neo4j.

This check box is available only if the **Use an existing connection** check box is not selected.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Query

Enter your Cypher query in double quotes. If you have some parameters corresponding to the input schema columns,
declare them with curly brackets ({})) and map them in the Parameters table.

| Parameters             | Click the [+] button to add parameters corresponding to your Cypher query and map them with the input schema columns.  
|------------------------|-------------------------------------------------------------------------------------------------|
|                        | • **Parameter name**: Type in the name of your parameter, in double quotes.  
|                        | • **Parameter value**: Select the schema column you want to map your parameter with.  

| Die on error           | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.  

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.  

| Commit every            | Enter the number of rows to be completed before committing batches of nodes together the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.  
|                        | This option is only supported by the embedded mode of the database. You cannot make transactions in REST mode, that is to say, not on a remote server in the deprecated 2.X.X versions.  

**Global Variables**

| Global Variables        | **NB_NODE_INSERTED**: the number of nodes inserted. This is an After variable and it returns a long.  
|                        | **NB_RELATIONSHIP_INSERTED**: the number of relationships inserted. This is an After variable and it returns a long.  
|                        | **NB_PROPERTY_UPDATED**: the number of properties updated. This is an After variable and it returns a long.  
|                        | **NB_NODE_DELETED**: the number of nodes deleted. This is an After variable and it returns a long.  
|                        | **NB_RELATIONSHIP_DELETED**: the number of relationships deleted. This is an After variable and it returns a long.  
|                        | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
|                        | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                        | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
|                        | For further information about variables, see Talend Studio User Guide.  

For further information about variables, see Talend Studio User Guide.
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as a standalone component or as an output component in a process.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

**Creating nodes with a label using a Cypher query**

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that creates nodes with a label in an embedded Neo4j database using a Cypher query, and then displays some properties of the specified node on the console.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a `tNeo4jConnection` component, to open a connection to a Neo4j database,
   - a `tNeo4jRow` component, to create nodes in the Neo4j database with a Cypher query,
   - a `tNeo4jInput` component, to read the specified properties of the created nodes,
   - a `tLogRow` component, to display the data on the Run console, and
   - a `tNeo4jClose` component, to close the Neo4j database connection established by the `tNeo4jConnection` component.

2. Link the `tNeo4jConnection` component to the `tNeo4jRow` component using a Trigger > On Subjob Ok connection.

3. Link the `tNeo4jRow` component to the `tNeo4jInput` component using a Trigger > On Subjob Ok connection.

4. Link the `tNeo4jInput` component to the `tLogRow` component using a Row > Main connection.

5. Link the `tNeo4jInput` component to the `tNeo4jClose` component using a Trigger > On Subjob Ok connection.
**Configuring the components**

**Configuring a Neo4j database connection and nodes creation**

**Procedure**

1. Double-click the `tNeo4jConnection` component to open its **Basic settings** view on the **Component** tab.

2. From the **DB Version** list, select **Neo4J 2.X.X** to enable node labeling support.

3. In the **Database path** field, specify the directory for your data files, "E:/Talend/DB/Neo4j/data" in this example.

   In this example, you will use Neo4j in embedded mode; to connect to a remote Neo4j server via REST, click the **Use a remote server** check box and specify the URL of the Neo4j server.
4. Double-click the \texttt{tNeo4jRow} component to open its Basic settings view on the Component tab.

5. Select the Use an existing connection check box to reuse the Neo4j database connection opened by the \texttt{tNeo4jConnection} component, which is the only connection component used in this example.

6. In the Query field, type in the Cypher query to be executed by the component.

In this example, type in the following query to create two nodes with the label Managers and three properties - id, name, and position:

```
"CREATE (a:Managers { id: 1, name: 'Gerald White', position: 'HR directory'})
CREATE (b:Managers { id: 2, name: 'Jimmy Black', position: 'Sales manager'})"
```

As this component does not have an input flow, leave the schema and the parameter settings blank.

Configuring data retrieving and display

Procedure

1. Double-click the \texttt{tNeo4jInput} component to open its Basic settings view.

2. Select the Use an existing connection check box to reuse the connection opened by the \texttt{tNeo4jConnection} component.
3. Click the [...] button next to Edit schema and define the schema corresponding to the node properties you want to retrieve and display. In this example, the schema is composed of two columns, name and position, both of type String.

When done, click OK to close the Schema dialog box and propagate the schema to the next component.

4. In the Query field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find the name and position of the manager whose ID is 2.

```
"MATCH (ee:Managers{id:2}) RETURN ee.name, ee.position;"
```

or

```
"MATCH (ee:Managers) WHERE ee.id = 2 RETURN ee.name, ee.position;"
```

5. Fill the Return parameter field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the tLogRow component to open its Basic settings view, and select the Table (print values in cells of a table) option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.

2. Press F6 or click Run on the Run tab to run the Job.
Two nodes are created in the Neo4j database based on the Cypher query, with the data files written in the specified directory, and the defined information is retrieved and displayed on the console.

**Importing data from a CSV file to Neo4j using a Cypher query**

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that first imports employees data from a CSV file into a Neo4j database using a Cypher query, and then displays the information on the console.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a `tNeo4jConnection` component, to open a connection to a Neo4j database,
   - a `tFileInputDelimited` component, to read the source data from a CSV file,
   - a `tNeo4jRow` component, to write the employees data to the Neo4j database with a Cypher query,
   - a `tNeo4jInput` component, to read the employees data from the Neo4j database,
   - a `tLogRow` component, to display the data on the Run console, and
   - a `tNeo4jClose` component, to close the Neo4j database connection opened by the `tNeo4jConnection` component.

2. Link the `tNeo4jConnection` component to the `tFileInputDelimited` component using a Trigger > On Subjob Ok connection.

3. Link the `tFileInputDelimited` component to the `tNeo4jRow` component using a Row > Main connection.

4. Link the `tFileInputDelimited` component to the `tNeo4jInput` component using a Trigger > On Subjob Ok connection.

5. Link the `tNeo4jInput` component to the `tLogRow` component using a Row > Main connection.

6. Link the `tNeo4jInput` component to the `tNeo4jClose` component using a Trigger > On Subjob Ok connection.

7. Label the components to better identify their roles in the Job.
Configuring the components

Configuring a Neo4j database connection

Procedure

1. Double-click the **tNeo4jConnection** component to open its **Basic settings** view on the **Component** tab.

   ![Open_Neo4j_connection](image)

   This component requires a Java 1.7.

2. From the DB Version list, select **Neo4J 2.X.X**.

3. Select the **Use a remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.
In this example, you will use Neo4j in REST mode; to connect to a remote Neo4j server in embedded mode, clear the **Use a remote server** check box and specify the Neo4j data file directory in the **Database path** field.

### Configuring data import

#### Procedure

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

   ![Basic settings](image)

2. In the **File name/Stream** field, specify the path to the CSV file that contains the employees data to read.

   The input CSV file used in this example is as follows:

   ```
   employeeID;employeeName;age;hireDate;salary;managerID
   1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
   2;Warren Adams;43;05-22-2008;11626.68;m6
   3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
   4;Herbert Quincy;54;06-14-2007;10694.71;m6
   5;Woodrow Polk;33;08-14-2007;13751.50;m4
   6;Theodore Johnson;47;01-26-2008;12426.87;m6
   7;Benjamin Adams;32;02-25-2008;10438.65;m4
   8;Woodrow Harrison;51;10-11-2008;11188.27;m5
   9;George Truman;40;04-28-2008;14254.49;m5
   10;Harry Jackson;38;04-01-2008;12798.78;m6
   ```

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the `[...]` button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: *employeeID* (integer), *employeeName* (String), *age* (Integer), *hireDate* (Date), *salary* (Double), and *managerID* (String).

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
5. Double-click the **tNeo4jRow** component to open its **Basic settings** view on the **Component** tab.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Query** field, type in the Cypher query to be executed by the component.

In this example, type in the following query to create nodes with the label **Employees** and six properties, to hold the data from the input flow:

- **ID**, which will take the value of the variable parameter **id**,
- **Name**, which will take the value of the variable parameter **name**,
- **Age**, which will take the value of the variable parameter **age**,
• **HireDate**, which will the value of the variable parameter *hire_date*,
• **Salary**, which will take the value of the variable parameter *salary*, and
• **ManagerID**, which will the value of the variable parameter *manager_id*.

```
"CREATE (n:Employees{ID:{id}, Name:{name}, Age:{age}, HireDate:{hire_date}, Salary:{salary}, ManagerID:{manager_id}})"
```

8. In the **Parameters** table, type in the variable parameters in the **Parameter** field in accordance with your Cypher query, and map each of them with an input schema column by selecting it from the **Parameter value** list field.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;id&quot;</td>
<td>employeeID</td>
</tr>
<tr>
<td>&quot;name&quot;</td>
<td>employeeName</td>
</tr>
<tr>
<td>&quot;age&quot;</td>
<td>age</td>
</tr>
<tr>
<td>&quot;hire_date&quot;</td>
<td>hireDate</td>
</tr>
<tr>
<td>&quot;salary&quot;</td>
<td>salary</td>
</tr>
<tr>
<td>&quot;manager_id&quot;</td>
<td>managerID</td>
</tr>
</tbody>
</table>

**Configuring data retrieving and display**

**Procedure**

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box to reuse the connection opened the **tNeo4jConnection** component.

3. Click the [...] button next to **Edit schema** and define the schema corresponding to the node properties you want to retrieve and display.

When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
The defined schema columns automatically appear in the Mapping table.

4. In the Query field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to retrieve all the properties of all the nodes with the label Employees.

```
"MATCH (n:Employees) RETURN *;"
```

5. Fill the Return parameter field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the tLogRow component to open its Basic settings view, and select the Table (print values in cells of a table) option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 or click Run on the Run tab to run the Job.
Importing data from a CSV file to Neo4j and creating relationships using a single Cypher query

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that imports family information from a CSV file into a remote Neo4j database and create relationships between persons and families using a single Cypher query through a tNeo4jRow component.

Below is content of the CSV file to import data from in this example:

<table>
<thead>
<tr>
<th>Name</th>
<th>Gender</th>
<th>Age</th>
<th>Family</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jenny</td>
<td>Female</td>
<td>24</td>
<td>the Johnsons</td>
</tr>
<tr>
<td>Jack</td>
<td>Male</td>

</tr>
</tbody>
</table>

As MERGE is used with LOAD CSV in this example, to ensure the Cypher query is executed in an efficient way, another tNeo4jRow component is used to create an index on the property to merge.

Adding and linking components

Procedure

1. Create a Job and add two tNeo4jRow components to the Job by typing the component name in the design workspace or dropping them from the Palette.
2. Link the components using a Trigger > On Sub Job Ok connection.
3. Label the components to better identify their roles in the Job.
Configuring the components

Creating an index

Procedure

1. Double-click the first `tNeo4jRow` component to open its Basic settings view on the Component tab.

2. From the DB Version list, select Neo4J 2.X.X.

3. Select the Remote server check box and specify the URL of the Neo4j server in the Server URL field, "http://localhost:7474/db/data" in this example.

4. In the Query field, type in the following query to create an index on the property you are going to merge, which is the name property of the Family nodes in this example:

   "CREATE INDEX ON :Family(name)"

Importing data and creating relationships

Procedure

1. Double-click the second `tNeo4jRow` component to open its Basic settings view on the Component tab.
2. From the **DB Version** list, select **Neo4J 2.X.X**.

3. Select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.

4. In the **Query** field, type in the following Cypher query to import family data from the CSV file, create relevant **Person** and **Family** nodes, and create relationships between persons and families:

   ```cypher
   "LOAD CSV WITH HEADERS FROM 'file:E:/Talend/Data/Input/families.csv' AS csvLine
   FIELDTERMINATOR ';'
   MERGE (family:Family { name: csvLine.Family })
   CREATE (person:Person { name: csvLine.Name, gender: csvLine.Gender, age: toInt(csvLine.Age)})
   CREATE (person)-[:From]->(family)"
   ```

   **Executing the Job and checking the result**

   **Procedure**

   1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.

   2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, `http://localhost:7474/` in this example, and enter the following Cypher query in the command line to view the **Person** and **Family** nodes linked via the relationship **From**:

   ```cypher
   MATCH (a:Person)-[:`From`]->(b:Family) RETURN a,b;
   ```

   As shown in the graphic view, nodes labeled **Family** and **Person** have been created and the nodes of persons from the same families are linked with the relevant **Family** nodes via the relationship **From**.
MATCH (a:Person)-[[:From]->(b:Family) RETURN a, b;
tNetezzaBulkExec

Offers gains in performance while carrying out the Insert operations to a Netezza database.

**tNetezzaBulkExec Standard properties**

These properties are used to configure tNetezzaBulkExec running in the Standard Job framework.

The Standard tNetezzaBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <em>Apply</em>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <em>Built-in</em> or <em>Repository</em>. <em>Built-in:</em> No property data stored centrally. <em>Repository:</em> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
</tbody>
</table>
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

<table>
<thead>
<tr>
<th><strong>Table</strong></th>
<th>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using tNetezzaBulkExec is deployed.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **Additional JDBC Parameters** | Specify additional JDBC parameters for the database connection being created. This property is not available when the Use an existing connection check box in the Basic settings view is selected. |
| **Field Separator** | Character, string or regular expression to separate fields. |
| **Escape character** | Character of the row to be escaped. |
| **Date format / Date delimiter** | Use Date format to distinguish the way years, months and days are represented in a string. Use Date delimiter to specify the separator between date values. |
Time format/ Time delimiter
Use Time format to distinguish the time is represented in a string. Use Time delimiter to specify the separator between time values.

Encoding
Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

Max Errors
Enter the maximum error limit that will not stop the process.

Skip Rows
Enter the number of rows to be skipped.

tStatCatcher Statistics
Select this check box to collect log data at the component level.

Global Variables

Global Variables

NB_LINE: the number of rows processed. This is an After variable and it returns an integer.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
This component is mainly used when non particular transformation is required on the data to be loaded on to the database.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic
connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

For use cases in relation with **tNetezzaBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tNetezzaClose

Closes the transaction committed in the connected Netezza database.

**tNetezzaClose Standard properties**

These properties are used to configure tNetezzaClose running in the Standard Job framework.

The Standard tNetezzaClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Component list</strong></td>
<td>Select the <strong>tNetezzaConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>tStat Catcher Statistics</strong></th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is to be used along with Netezza components, especially with <strong>tNetezzaConnection</strong> and <strong>tNetezzaCommit</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. </tr>
<tr>
<td>----------------</td>
<td>-----------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
Related scenarios

No scenario is available for the Standard version of this component yet.
tNetezzaCommit

Validates the data processed through the Job into the connected Netezza database.

Using a unique connection, tNetezzaCommit commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tNetezzaCommit Standard properties**

These properties are used to configure tNetezzaCommit running in the Standard Job framework.

The Standard tNetezzaCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

_If you want to use a Row > Main connection to link tNetezzaCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit._

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tNetezza* components, especially with the tNetezzaConnection and tNetezzaRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tNetezzaCommit related scenario, see Inserting data in mother/daughter tables on page 2452.
**tNetezzaConnection**

Opens a connection to a Netezza database to be reused in the subsequent subJob or subJobs.

**tNetezzaConnection Standard properties**

These properties are used to configure tNetezzaConnection running in the Standard Job framework.

The Standard tNetezzaConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
<tr>
<td></td>
<td>This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together</td>
</tr>
</tbody>
</table>
with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

### Usage

| **Usage rule** | This component is more commonly used with other `tNetezza*` components, especially with the `tNetezzaCommit` and `tNetezzaRollback` components. |
| **Limitation** | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the `Install` button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For a `tNetezzaConnection` related scenario, see Inserting data in mother/daughter tables on page 2452.
tNetezzaInput

Reads a database and extracts fields from a Netezza database based on a query.

`tNetezzaInput` executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

tNetezzaInput Standard properties

These properties are used to configure `tNetezzaInput` running in the Standard Job framework.
The `Standard` `tNetezzaInput` component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view. For more information about setting up and storing database connection parameters, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Table Name | Name of the table to be read. |
**Query type and Query**
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Advanced settings

| **Additional JDBC Parameters** | Specify additional JDBC parameters for the database connection being created.  
This property is not available when the **Use an existing connection** check box in the **Basic settings** view is selected. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use cursor</strong></td>
<td>When selected, helps to decide the row set to work with at a time and thus optimize performance.</td>
</tr>
<tr>
<td><strong>Trim all the String/Char columns</strong></td>
<td>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</td>
</tr>
<tr>
<td><strong>Trim column</strong></td>
<td>Remove leading and trailing whitespace from defined columns.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

| **Global Variables** | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

### Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component covers all possible SQL queries for Netezza databases.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an</td>
</tr>
</tbody>
</table>
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2472 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 495. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Related scenarios

Related scenarios for **tNetezzaInput** are:

- [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 495.
tNetezzaNzLoad

 Inserts data into a Netezza database table using Netezza’s nzload utility.

 tNetezzaNzLoad bulk loads data into a Netezza table either from an existing data file, an input flow, or directly from a data flow in streaming mode through a named-pipe.

 tNetezzaNzLoad Standard properties

 These properties are used to configure tNetezzaNzLoad running in the Standard Job framework.

 The Standard tNetezzaNzLoad component belongs to the Databases family.

 The component in this framework is available in all Talend products.

 Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-in or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of the DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the Netezza database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table into which the data is to be inserted.</td>
</tr>
</tbody>
</table>

 Action on table

 On the table defined, you can perform one of the following operations before loading the data:

 **None**: No operation is carried out.

 **Drop and create a table**: The table is removed and created again.

 **Create a table**: The table does not exist and gets created.

 **Create table if not exists**: The table is created if it does not exist.

 **Drop table if exists and create**: The table is removed if it already exists and created again.

 **Clear table**: The table content is deleted before the data is loaded.

 **Truncate table**: executes a truncate statement prior to loading the data to clear the entire content of the table.
### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

<table>
<thead>
<tr>
<th><strong>Built-In</strong></th>
<th>You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide.</em></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide.</em></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Data file

Full path to the data file to be used. If this component is used on its own (not connected to another component with input flow) then this is the name of an existing data file to be loaded into the database. If it is connected, with an input flow to another component; this is the name of the file to be generated and written with the incoming data to later be used with nzload to load into the database.

### Use named-pipe

Select this check box to use a named-pipe instead of a data file. This option can only be used when the component is connected with an input flow to another component. When the check box is selected, no data file is generated and the data is transferred to nzload through a named-pipe. This option greatly improves performance in both Linux and Windows.

**Note:**

This component on named-pipe mode uses a JNI interface to create and write to a named-pipe on any Windows platform. Therefore the path to the associated JNI DLL must be configured inside the java library path. The component comes with two DLLs for both 32 and 64 bit operating systems that are automatically provided in the Studio with the component.

### Named-pipe name

Specify a name for the named-pipe to be used. Ensure that the name entered is valid.
**Advanced settings**

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection being created.</td>
</tr>
<tr>
<td><strong>Use existing control file</strong></td>
<td>Select this check box to provide a control file to be used with the nzload utility instead of specifying all the options explicitly in the component. When this check box is selected, <strong>Data file</strong> and the other nzload related options no longer apply. Please refer to Netezza’s nzload manual for details on creating a control file.</td>
</tr>
<tr>
<td><strong>Control file</strong></td>
<td>Enter the path to the control file to be used, between double quotation marks, or click [... ] and browse to the control file. This option is passed on to the nzload utility via the -cf argument.</td>

</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>This is nzload’s delim argument. If you do not use the Wrap quotes around fields option, you must make sure that the delimiter is not included in the data that’s inserted to the database. The default value is \t or TAB. To improve performance, use the default value.</td>
</tr>
<tr>
<td><strong>Wrap quotes around fields</strong></td>
<td>This option is only applied to columns of String, Byte, Byte[], Char, and Object types. Select either:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: do not wrap column values in quotation marks.</td>
</tr>
<tr>
<td></td>
<td><strong>Single quote</strong>: wrap column values in single quotation marks.</td>
</tr>
<tr>
<td></td>
<td><strong>Double quote</strong>: wrap column values in double quotation marks.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>If using the Single quote or Double quote option, it is necessary to use \ as the Escape char.</td>
</tr>
<tr>
<td><strong>Advanced options</strong></td>
<td>Set the nzload arguments in the corresponding table. Click [+] as many times as required to add arguments to the table. Click the Parameter field and choose among the arguments from the list. Then click the corresponding Value field and enter a value between quotation marks. For details about the available parameters, see Parameters on page 2659.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding type from the list.</td>
</tr>
<tr>
<td><strong>Specify nzload path</strong></td>
<td>Select this check box to specify the full path to the nzload executable. You must check this option if the nzload path is not specified in the PATH environment variable.</td>
</tr>
</tbody>
</table>
**Full path to nzload executable**

Full path to the nzload executable on the machine in use. It is advisable to specify the nzload path in the PATH environment variable instead of selecting this option.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

This component is mainly used when non particular transformation is required on the data to be loaded onto the database.

This component can be used as a standalone or an output component.

### Parameters

The following table lists the parameters you can use in the **Advanced options** table in the **Advanced settings** tab.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>-if</strong></td>
<td>Name of the log file to generate. The logs will be appended if the log file already exists. If the parameter is not specified, the default name for the log file is <code>&lt;table_name&gt;.&lt;db_name&gt;.nzlog</code>. And it’s generated under the current working directory where the job is running.</td>
</tr>
<tr>
<td><strong>-bf</strong></td>
<td>Name of the bad file to generate. The bad file contains all the records that could not be loaded due to an internal Netezza error. The records will be appended if the bad file already exists. If the parameter is not specified, the default name for the bad file is <code>&lt;table_name&gt;.&lt;db_name&gt;.nzbad</code>. And it’s generated under the current working directory where the job is running.</td>
</tr>
<tr>
<td><strong>-outputDir</strong></td>
<td>Directory path to where the log and the bad file are generated. If the parameter is not specified the files are generated under the current working directory where the job is running.</td>
</tr>
</tbody>
</table>
-logFileSize

Maximum size for the log file. The value is in MB. The default value is 2000 or 2GB. To save hard disk space, specify a smaller amount if your job runs often.

-compress

Specify this option if the data file is compressed. Valid values are "TRUE" or "FALSE". Default value if "FALSE". This option is only valid if this component is used by itself and not connected to another component via an input flow.

-skipRows <n>

Number of rows to skip from the beginning of the data file. Set the value to "1" if you like to skip the header row from the data file. The default value is "0". This option should only be used if this component is used by itself and not connected to another component via an input flow.

-maxRows <n>

Maximum number of rows to load from the data file. This option should only be used if this component is used by itself and not connected to another component via an input flow.

-maxErrors

Maximum number of error records to allow before terminating the load process. The default value is "1".

-ignoreZero

Binary zero bytes in the input data will generate errors. Set this option to "NO" to generate error or to "YES" to ignore zero bytes. The default value is "NO".

-requireQuotes

This option requires all the values to be wrapped in quotes. The default value is "FALSE". This option currently does not work with input flow. Use this option only in standalone mode with an existing file.

-nullValue <token>

Specify the token to indicate a null value in the data file. The default value is "NULL". To improve slightly performance you can set this value to an empty field by specifying the value as single quotes: "\"".

-fillRecord

Treat missing trailing input fields as null. You do not need to specify a value for this option in the value field of the table. This option is not turned on by default, therefore input fields must match exactly all the columns of the table by default.

Trailing input fields must be nullable in the database.

-ctrlChar

Accept control chars in char/varchar fields (must escape NUL, CR and LF). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.

-ctInString

Accept un-escaped CR in char/varchar fields (LF becomes only end of row). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-truncString</td>
<td>Truncate any string value that exceeds its declared char/varchar storage. You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>-dateStyle</td>
<td>Specify the date format in which the input data is written in. Valid values are: &quot;YMD&quot;, &quot;Y2MD&quot;, &quot;DMY&quot;, &quot;DMY2&quot;, &quot;MDY&quot;, &quot;MONDY&quot;, &quot;MONDY2&quot;. The default value is &quot;YMD&quot;. The date format of the column in the component’s schema must match the value specified here. For example if you want to load a DATE column, specify the date format in the component schema as ‘yyyy-MM-dd’ and the -dateStyle option as ‘YMD’. For more description on loading date and time fields, see Loading DATE, TIME and TIMESTAMP columns on page 2662.</td>
</tr>
<tr>
<td>-dateDelim</td>
<td>Delimiter character between date parts. The default value is &quot;&quot; for all date styles except for &quot;MONDY[2]&quot; which is &quot; &quot; (empty space). The date format of the column in the component’s schema must match the value specified here.</td>
</tr>
<tr>
<td>-y2Base</td>
<td>First year expressible using two digit year (Y2) dateStyle.</td>
</tr>
<tr>
<td>-timeStyle</td>
<td>Specify the time format in which the input data is written in. Valid values are: &quot;24HOUR&quot; and &quot;12HOUR&quot;. The default value is &quot;24HOUR&quot;. For slightly better performance you should keep the default value. The time format of the column in the component’s schema must match the value specified here. For example if you want to load a TIME column, specify the date format in the component schema as ‘HH:mm:ss’ and the -timeStyle option as ‘24HOUR’. For more description on loading date and time fields, see Loading DATE, TIME and TIMESTAMP columns on page 2662.</td>
</tr>
<tr>
<td>-timeDelim</td>
<td>Delimiter character between time parts. The default value is &quot;.&quot;.</td>
</tr>
<tr>
<td>-timeRoundNanos</td>
<td>Allow but round non-zero digits with smaller than microsecond resolution.</td>
</tr>
<tr>
<td>-boolStyle</td>
<td>Specify the format in which Boolean data is written in the data. The valid values are: &quot;1_0&quot;, &quot;T_F&quot;, &quot;Y_N&quot;, &quot;TRUE_FALSE&quot;, &quot;YES&quot;. The default value is &quot;1_0&quot;. For slightly better performance keep the default value.</td>
</tr>
<tr>
<td>-allowRelay</td>
<td>Allow load to continue after one or more SPU reset or failed over. The default behaviour is not allowed.</td>
</tr>
</tbody>
</table>
-allowRelay <n> Specify number of allowable continuation of a load. Default value is "1".

**Loading DATE, TIME and TIMESTAMP columns**

When this component is used with an input flow, the date format specified inside the component’s schema must match the value specified for -dateStyle, -dateDelim, -timeStyle, and -timeDelim options.

<table>
<thead>
<tr>
<th>DB Type</th>
<th>Schema date format</th>
<th>-dateStyle</th>
<th>-dateDelim</th>
<th>-timeStyle</th>
<th>-timeDelim</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>&quot;yyyy-MM-dd&quot;</td>
<td>&quot;YMD&quot;</td>
<td>&quot;:&quot;</td>
<td>n/a</td>
<td>n/a</td>
</tr>
<tr>
<td>TIME</td>
<td>&quot;HH:mm:ss&quot;</td>
<td>n/a</td>
<td>n/a</td>
<td>&quot;24HOUR&quot;</td>
<td>&quot;:&quot;</td>
</tr>
<tr>
<td>TIMESTAMP</td>
<td>&quot;yyyy-MM-dd HH:mm:ss&quot;</td>
<td>&quot;YMD&quot;</td>
<td>&quot;:&quot;</td>
<td>&quot;24HOUR&quot;</td>
<td>&quot;:&quot;</td>
</tr>
</tbody>
</table>

**Related scenario**

For a related use case, see [Inserting data in bulk in MySQL database](#) on page 2515.
tNetezzaOutput

 Writes, updates, makes changes or suppresses entries in a Netezza database.

 tNetezzaOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the designed Job.

 tNetezzaOutput Standard properties

 These properties are used to configure tNetezzaOutput running in the Standard Job framework.

 The Standard tNetezzaOutput component belongs to the Databases family.

 The component in this framework is available in all Talend products.

 Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

 Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>Default</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop a table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear a table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
### Warning:

It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that:
- Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

---

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

**Built-In:** You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to Built-in for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.
### Advanced settings

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.

**Note:**
You can press **Ctrl+Space** to access a list of predefined global variables. |
| **Use Batch** | Select this check box to activate the batch mode for data processing.

**Note:**
This check box is available only when you have selected the **Insert**, **Update** or the **Delete** option in the **Action on data** list. |
| **Batch Size** | Specify the number of records to be processed in each batch.
This field appears only when the **Use batch mode** check box is selected. |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at executions. |
| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

**Name:** Type in the name of the schema column to be altered or inserted as new column

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position:** Select **Before**, **Replace** or **After** following the action to be performed on the reference column.

**Reference column:** Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column. |
| **Use field options** | Select this check box to customize a request, especially when there is double action on data. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</td>
</tr>
<tr>
<td>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Netezza database. It also allows you to create a reject flow using a Row &gt; Rejects link to filter data in error. For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2500.</td>
</tr>
</tbody>
</table>

Dynamic settings

<table>
<thead>
<tr>
<th>Dynamic settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
<tr>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.</td>
</tr>
<tr>
<td>For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic 2667</td>
</tr>
</tbody>
</table>
settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For tNetezzaOutput related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2492.
tNetezzaRollback

Cancels the transaction committed in the connected Netezza database to avoid committing part of a transaction involuntarily.

**tNetezzaRollback Standard properties**

These properties are used to configure tNetezzaRollback running in the Standard Job framework.

The Standard tNetezzaRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tNetezzaConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tNetezza* components, especially with the <strong>tNetezzaConnection</strong> and <strong>tNetezzaCommit</strong> components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection</td>
</tr>
</tbody>
</table>
Related scenarios

For tNetezzaRollback related scenario, see Rollback from inserting data in mother/daughter tables on page 2455.
tNetezzaRow

Executes the SQL query stated onto the specified Netezza database.

Depending on the nature of the query and the database, tNetezzaRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tNetezzaRow is the specific component for this database query. It implements a flow in the job design although it does not provide output.

**tNetezzaRow Standard properties**

These properties are used to configure tNetezzaRow running in the Standard Job framework.

The Standard tNetezzaRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window.

**Table Name**
Enter the name of the table to be processed.

**Query type**
Either **Built-in** or **Repository**.

- **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder
- **Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Query**
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Die on error**
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC parameters</strong></td>
<td>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <em>Use an existing connection</em> check box in the <strong>Basic settings</strong>.</td>
</tr>
</tbody>
</table>
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.  

**Note:** This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by '?' in the SQL instruction of the **Query** field in the **Basic Settings** tab.  

**Parameter Index:** Enter the parameter position in the SQL instruction.  

**Parameter Type:** Enter the parameter type.  

**Parameter Value:** Enter the parameter value.  

**Note:** This option is very useful if you need to execute the same query several times. Performance levels are increased. |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>NB_EFFECTED</strong></td>
<td>the number of effected rows. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <em>Die on error</em> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Limitation

| Limitation       | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Related scenarios

For related scenarios, see:

- Combining two flows for selective output on page 2529
- Removing and regenerating a MySQL table index on page 2523
tNetezzaSCD

Reflects and tracks changes in a dedicated Netezza SCD table.

tNetezzaSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tNetezzaSCD Standard properties**

These properties are used to configure tNetezzaSCD running in the Standard Job framework.

The Standard tNetezzaSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all *Talend products*.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see *Dynamic database components on page 608*.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
</tr>
<tr>
<td>1.</td>
<td>In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection.</td>
</tr>
<tr>
<td>2.</td>
<td>In the child level, use a dedicated connection component to read that registered database connection.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>For an example about how to share a database connection across Job levels, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td>---------------</td>
<td>-----------------------</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |
| **Action on table** | Select to perform one of the following operations on the table defined:  
- **None**: No action is carried out on the table.  
- **Create table**: A new table is created.  
- **Create table if not exists**: A table is created if it does not exist. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.  
For more information, see SCD management methodology on page 2537. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. |
**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</th>
</tr>
</thead>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</th>
</tr>
</thead>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The <strong>Dynamic settings</strong> table is available only when the <strong>Use an existing connection</strong> check box is selected in the <strong>Basic settings</strong> view. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on <strong>Dynamic settings</strong> and context variables, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Limitation</td>
<td>This component does not support using SCD type 0 together with other SCD types.</td>
</tr>
</tbody>
</table>

Related scenario

For related scenarios, see **tMysqlSCD** on page 2534.
tNetsuiteConnection

Creates a connection to the NetSuite SOAP server so that other NetSuite components in the Job can reuse the connection.

**tNetsuiteConnection Standard properties**

These properties are used to configure tNetsuiteConnection running in the Standard Job framework.

The Standard tNetsuiteConnection component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Endpoint</strong></td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td><strong>API version</strong></td>
<td>Select the version of the NetSuite API you are connecting to. As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>
</tr>
<tr>
<td><strong>E-mail and Password</strong></td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Role</strong></td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td><strong>Account</strong></td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td><strong>Application ID</strong></td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Enable customizations</strong></td>
<td>Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the Record Type dialog box, and custom fields will be retrieved and included into the schema. This option is enabled by default. You can disable it if you don’t need custom record types or custom fields. With this option enabled in the tNetsuiteConnection component, all the other components using this connection will have this option enabled.</td>
</tr>
</tbody>
</table>
### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is more commonly used with other NetSuite components. |

### Related scenario

No scenario is available for this component yet.
tNetsuiteInput

Invokes the NetSuite SOAP service and retrieves data according to the conditions you specify.

**tNetsuiteInput Standard properties**

These properties are used to configure tNetsuiteInput running in the Standard Job framework.

The Standard tNetsuiteInput component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</th>

<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>
| **Search conditions** | Define search conditions to match fields for data retrieval. Click the `[+]` button to add as many rows as you need, each row for a condition, and define each of your conditions:  
  - **Field**: select a field to search based on the condition.  
  - **Operator**: select an operator for the field search condition.  
  - **Value**: enter the value for the field search condition.  
  - **Value 2**: enter the second value for the field search condition, if relevant depending on the operator you select. |
| **Advanced settings** |  |
| **Body fields only** | Select this check box to retrieve only body fields.  
Clear this check box to retrieve body fields and sublist values. |
| **Enable customizations** | Select this check box to instruct the component to retrieve customizations - custom record types and custom fields.  
With this option enabled, custom record types will be retrieved and can be selected in the *Record Type* dialog box, and custom fields will be retrieved and included into the schema.  
This option is enabled by default. You can disable it if you don’t need custom record types or custom fields. |

**Warning:**
The schema of this component is dynamically filled with columns corresponding to the NetSuite service fields, which vary depending on the *Record Type* selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors.
tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

Global Variables

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

Usage rule

This component is usually used as a start component in a *Talend* flow and it requires an output component.

Handling data with NetSuite

This scenario describes a Job that reads data from NetSuite, transforms the data and writes the transformed data to NetSuite, finally displays the transformed data on the console.

Adding the components

Create a new Job and add the following five components by typing their names in the design workspace or dropping them from the **Palette**:
**tNetsuiteInput**

- two **tNetsuiteInput** components: to read data that matches the specified search criteria from the NetSuite server.
- a **tMap** component: to transform the input data to the output structure.
- a **tNetsuiteOutput** component: to write the transformed data into the NetSuite server.
- a **tLogRow** component: to display the data received from the NetSuite server.

**Configuring and linking the components**

**Reading, transforming, and writing data in NetSuite**

**Procedure**

1. Double-click the first **tNetsuiteInput** to open its **Basic settings** view.

![Basic settings view](image)

2. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

3. Click the [...] button next to the **Record Type** field, and from the dialog box that opens select **Location** to read the location type information from NetSuite.
   
   The schema corresponding to the location record type is automatically retrieved.

4. Define a search condition.
   a) Click the [+ ] button below the **Search conditions** table to add one row.
   b) Click the cell of the **Field** column and select **internalId** from the drop-down list.
   c) Click the cell of the **Operator** column and select **List - Any Of** from the drop-down list.
   d) In the cell of the **Value** column, enter `java.util.Arrays.asList("1")` to retrieve only the record whose **internalId** is set to 1.

5. Connect the first **tNetsuiteInput** to **tMap** using a **Row > Main** connection.

6. Double-click **tNetsuiteOutput** to open its **Basic settings** view.
7. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

8. In the **Action** list, select **insert** to insert the transformed data into NetSuite.

9. Click the [...] button next to the **Record Type** field, and in the dialog box that opens select **Location** to write the location type information into NetSuite.

10. Click the [...] button next to **Edit schema** to open the schema editor. You can see the schema has already been prefilled. Keep only the columns that are relevant to your operation and delete others. In this example, keep the column **Name**, **Parent**, **IncludeChildren**, **IsInactive**, **TranPrefix**, **Logo**, **MakeInventoryAvailable**, **MakeInventoryAvailableStore**, **CustomFieldList**, and **ExternalId**.

11. Connect **tMap** to **tNetsuiteOutput** using a **Row > *New Output* (Main)** connection. In the pop-up dialog box, enter the name of the output connection, **out** in this example. Then click **Yes** to let **tMap** get the schema of the target component **tNetsuiteOutput**.

12. Double-click **tMap** to open its **Map Editor** and configure data flow mappings.
a) In the out output table, set the value of the Name column by entering "Paris" in the corresponding Expression column field.

b) Drag and drop the Parent column in the row1 input table onto the Expression column of the corresponding row in the out output table.

c) Do the same to drag and drop other columns IncludeChildren, IsInactive, TranPrefix, Logo, MakeInventoryAvailable, MakeInventoryAvailableStore, CustomFieldList, and ExternalId in the row1 input table onto the Expression column of the corresponding row in the out output table.

Retrieving the transformed data from NetSuite

Procedure

1. Double-click the second tNetSuiteInput to open its Basic settings view.
2. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

3. Click the [...] button next to the **Record Type** field, and from the dialog box that opens select **Location** to read the location type information from NetSuite.

   The schema corresponding to the location record type is automatically retrieved.

4. Define a search condition.
   a) Click the [+] button below the **Search condition** table to add one row.
   b) Click the cell of the **Field** column and select **name** from the drop-down list.
   c) Click the cell of the **Operator** column and select **String - Contains** from the drop-down list.
   d) In the cell of the **Value** column, enter **Paris** to retrieve only the record whose **name** contains **Paris**.

5. Double-click **tLogRow** to open its **Basic settings** view.

6. In the **Mode** area, select **Vertical (each row is a key/value list)** for better readability of the result.

7. Connect the second **tNetsuiteInput** to **tLogRow** using a **Row > Main** connection.

8. Connect the first **tNetsuiteInput** to the second **tNetsuiteInput** using a **Trigger > OnSubjobOk** connection.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

As shown above, the data has been transformed and written into NetSuite, then the transformed data is retrieved from NetSuite and displayed on the console.
**tNetsuiteOutput**

Invokes the NetSuite SOAP service and inserts, updates, or removes data on the NetSuite SOAP server.

**tNetsuiteOutput Standard properties**

These properties are used to configure tNetsuiteOutput running in the Standard Job framework.

The Standard tNetsuiteOutput component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Component</td>
<td>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</td>
</tr>
<tr>
<td>Endpoint</td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td>API version</td>
<td>Select the version of the NetSuite API you are connecting to. As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>

<td>Makes changes to an existing record.</td>
</tr>
<tr>
<td><strong>Upsert</strong></td>
<td>Updates the record corresponding to the specified ID, or inserts a new record if it does not exist.</td>
</tr>
<tr>
<td><strong>Delete</strong></td>
<td>Removes an existing record.</td>
</tr>
</tbody>
</table>

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Warning:**

The schema of this component is prefilled with columns corresponding to the NetSuite service fields, which vary depending on the **Record Type** selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors.
If the record corresponding to the specified Internal ID does not exist and the Die on error check box is selected, the Job stops.

To use this option, the InternalId column must exist in the schema and set as Key.

**Sync outgoing schema**

After the component schema is updated, click this button to propagate the schema to the outgoing flow(s), which can be a normal flow, a reject flow, or both, if the component has any.

### Advanced settings

**Enable customizations**

Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the Record Type dialog box, and custom fields will be retrieved and included into the schema.

This option is enabled by default. You can disable it if you don’t need custom record types or custom fields.

**Use native Upsert operation**

Select this check box to use the Upsert operation provided by NetSuite.

To use NetSuite’s Upsert operation, the ExternalId column must exist in the schema and set as Key.

This option is available when Upsert is selected from the Action list in Basic settings.

By default, for compatibility reasons, this option is disabled and the component performs the Add or Update action for an upsert depending on whether the record ID is specified.

**Batch size**

Specify the number of records to be processed in each batch.

Note that batching will be disabled if the output component has an outgoing flow.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **CURRENT_INTERNALID**: The internal ID of the record currently inserted or processed. This is a Flow variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| Usage rule | This component is usually used as an end component in a Talend flow and it requires an input component. |

**Related scenario**

For a related scenario, see Handling data with NetSuite on page 2683.
tNormalize

Normalizes the input flow following SQL standard to help improve data quality and thus eases the data update.

tNormalize Standard properties

These properties are used to configure tNormalize running in the Standard Job framework.
The Standard tNormalize component belongs to the Processing family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |

| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |

| Column to normalize | Select the column from the input flow which the normalization is based on. |

| Item separator | Enter the separator which will delimit data in the input flow.

Note:
The item separator is based on regular expressions, so the character "." (a special character for regular expression) should be avoided or used carefully here.
### Advanced settings

<table>

<tr>
<td>Use CSV parameters</td>
<td>Select this check box to include CSV specific parameters such as escape mode and enclosure character.</td>
</tr>
<tr>
<td>Discard the trailing empty strings</td>
<td>Select this check box to discard the trailing empty strings.</td>
</tr>
<tr>
<td>Trim resulting values</td>
<td>Select this check box to trim leading and trailing whitespace from the resulting data.</td>
</tr>
</tbody>
</table>

**Note:** When both Discard the trailing empty string and Trim resulting values check boxes are selected, the former works first.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_LINE</td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component can be used as intermediate step in a data flow.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
<td></td>
</tr>
</tbody>
</table>
Normalizing data

This simple scenario illustrates a Job that normalizes a list of tags for Web forum topics, and displays the result in a table on the Run console.

This list is not well organized and it contains trailing empty strings, leading and trailing whitespace, and repeated tags, as shown below.

ldap,
db2, jdbc driver,
grid computing, talend architecture,
content, environment,,
tmap,,
eclipse,
database, java, postgresql,
tmap,
database, java, sybase,
deployment,,
repository,
database, informix, java

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: tFileInputDelimited, tNormalize, tLogRow.

2. Connect the components using Row > Main connections.

Configuring the components

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view.

2. In the File name field, specify the path to the input file to be normalized.
3. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and set up the input schema by adding one column named **Tags**. When done, click **OK** to validate your schema setup and close the dialog box, leaving the rest of the settings as they are.

4. Double-click the **tNormalize** component to open **Basic settings** view.

5. Check the schema, and if necessary, click **Sync columns** to get the schema synchronized with the input component.

6. Define the column the normalization operation is based on.
   In this use case, the input schema has only one column, **Tags**, so just accept the default setting.

7. In the **Advanced settings** view, select the **Get rid of duplicate rows from output**, **Discard the trailing empty strings**, and **Trim resulting values** check boxes.

8. In the **tLogRow** component, select the **Print values in the cells of table** radio button.
Saving and executing the Job

Procedure

1. Press **Ctrl+S** to save your Job.
2. Click Run on the Run tab or press **F6** to execute the Job.

The list is tidied up, with duplicate tags, leading and trailing whitespace and trailing empty strings removed, and the result is displayed in a table cell on the console.
**tOleDbInput (deprecated)**

Executes a DB query with a strictly defined order which must correspond to the schema definition and passes on the field list to the next component via a Main row link.

This component reads a database and extracts fields based on a query. It offers the flexibility benefit of the DB query and covers all possible SQL queries.

### tOleDbInput Standard properties

These properties are used to configure tOleDbInput running in the Standard Job framework.

The Standard tOleDbInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

#### Basic settings

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. |
| **Built-In**: You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://docs.talend.com/user-guide). | **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://docs.talend.com/user-guide). |
| **Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:** | |
| • **View schema**: choose this option to view the schema only. | **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. | **Table Name** | Enter the name of the table to be processed. |
| | **Query Type** | Select either **Built-in** or **Repository** query type from the drop-down list. |
### tOleDbInput (deprecated)

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in</td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td>Guess Query</td>
<td>Click the button to generate the query which corresponds to the defined table schema in the Query field.</td>
</tr>
<tr>
<td>Guess schema</td>
<td>Click the button to retrieve the schema from the table.</td>
</tr>
<tr>
<td>Query</td>
<td>Specify the database query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
</tbody>
</table>

#### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Trim all the String/Char columns</td>
<td>Select this check box to remove leading and trailing whitespace from all the String/Char columns.</td>
</tr>
<tr>
<td>Trim column</td>
<td>Select the check box in Trim column to remove leading and trailing whitespace from the corresponding column. This field appears only when the Trim all the String/Char columns check box is cleared.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

#### Global Variables

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

#### Usage

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Usage rule</td>
<td>This component is used as a start component in a Job and it always needs an output link.</td>
</tr>
</tbody>
</table>
Related scenario

For similar scenarios, see tMysqlInput on page 2463.
tOleDbOutput (deprecated)

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

This component writes, updates, makes changes or suppresses entries in a database.

tOleDbOutput Standard properties

These properties are used to configure tOleDbOutput running in the Standard Job framework.

The Standard tOleDbOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Enter the connection string used to open the database. For details, please see <a href="http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx">http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Table</td>
<td>Specify the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td>Action on data</td>
<td>Select one of the following actions that you want to perform on the data from the drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• Insert: insert data.</td>
</tr>
<tr>
<td></td>
<td>• Update: update data.</td>
</tr>
<tr>
<td></td>
<td>• Insert or update: insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>• Update or insert: update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>• Delete: delete data.</td>
</tr>
</tbody>
</table>

Warning:
It is necessary to specify at least one column as a primary key on which the Update or Delete operation is based. You can do that by clicking Edit schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update or Delete operation. To do that, select the Use field options check box and then in the Key in update or Key in delete column, select the check box(es) next to the column name(s) you want to use as a base for the Update or Delete operation.

<table>
<thead>
<tr>
<th>Clear data in table</th>
<th>Select this check box to delete data in the defined table before any operation.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next</td>
</tr>
</tbody>
</table>
component. When you create a Spark Job, avoid the reserved word \textit{line} when naming the fields.

<table>
<thead>
<tr>
<th><strong>Built-In:</strong> You create and store the schema locally for this component only. Related topic: see \textit{Talend Studio User Guide}.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see \textit{Talend Studio User Guide}.</td>
</tr>
</tbody>
</table>

Click \textit{Edit schema} to make changes to the schema. If the current schema is of the \textit{Repository} type, three options are available:

- \textit{View schema}: choose this option to view the schema only.
- \textit{Change to built-in property}: choose this option to change the schema to \textit{Built-in} for local changes.
- \textit{Update repository connection}: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select \textit{No} upon completion and choose this schema metadata again in the \textit{Repository Content} window.

### Advanced settings

#### Additional columns

This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing.

- **Name**: Type in the name of the schema column to be altered or inserted.
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column.
- **Position**: Select \textit{Before}, \textit{After} or \textit{Replace}, depending on the action to be performed on the reference column.
- **Reference column**: Type in a reference column used to locate or replace the new column, or the column to be modified.

This option is not available if you have just created the DB table (even if you delete it beforehand).

#### Use field options

Select this check box to customize a request, especially if multiple actions are being carried out on the data.

#### Field options

Select the check box(es) in the table if you want to use the corresponding schema column(s) as a base for your operation.

- **Key in update**: define the primary key to use in an update operation.
- **Key in delete**: define the primary key to use in a delete operation.
- **Updatable**: define the column(s) to update.
- **Insertable**: define the column(s) to insert.
This field appears only when the Use field options check box is selected.

**Enable debug mode**
Select this check box to display each step involved in the process of writing data in the database.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>QUERY: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**
This component is normally an end component of a Job and always needs an input link.

### Related scenario

For similar scenarios, see [tMysqlOutput](#) on page 2486.
tOleDbRow (deprecated)

Acts on the actual database structure or on the data depending on the nature of the query and the database.

tOleDbRow is the specific component for this database query. It executes the SQL query stated in the specified database.

**tOleDbRow Standard properties**

These properties are used to configure tOleDbRow running in the Standard Job framework.

The Standard tOleDbRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Enter the connection string that contains the database. For details, see <a href="http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx">http://msdn.microsoft.com/en-us/library/system.data.oledb.oledbconnection.connectionstring.aspx</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <em>line</em> when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td>Table Name</td>
<td>Name of the table to be processed.</td>
</tr>
<tr>
<td>Query type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: Fill in manually the query statement or build it graphically using SQLBuilder</td>
<td></td>
</tr>
</tbody>
</table>
**Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Guess Query**: Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

**Query**: Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Die on error**: This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

### Advanced settings

**Propagate QUERY’s recordset**: Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the **use column** list.

**Use PreparedStatement**: Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters.

- **Parameter Index**: Enter the parameter position in the SQL instruction.
- **Parameter Type**: Enter the parameter type.
- **Parameter Value**: Enter the parameter value.

**tStatCatcher Statistics**: Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the database query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

### Related scenario

For similar scenarios, see tMysqlRow on page 2519.
tOpenbravoERPIInput

Extracts data from OpenBravoERP database according to the conditions defined in specific columns. tOpenbravoERPIInput connects to an OpenBravoERP database entity via the appropriate Web service.

**tOpenbravoERPIInput Standard properties**

These properties are used to configure tOpenbravoERPIInput running in the Standard Job framework. The Standard tOpenbravoERPIInput component belongs to the Business family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Openbravo REST WebService URL</th>
<th>Enter the URL of the Web service that allows you to connect to the OpenbravoERP database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Username and Password</td>
<td>User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Entity</td>
<td>Select the appropriate entity from the drop-down list.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: • View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
</tr>
</tbody>
</table>

**Note:**
For this component, the schema corresponds to a selected entity.

| WHERE Clause | Enter your WHERE clause. |
Order by

Select this check box to define how to order the results (the elements in the drop-down list depend on the entity selected).

Sort: Choose whether to organise the results in either Ascending or Descending order.

First result

Enter the row number you want to retrieve first.

Max result

Enter the maximum number of results you want to retrieve.

Advanced settings

Advanced separator (for numbers)

Select this check box to modify the separators to be used for the numbers. Either:

- Thousands separator
- Decimal separator

tStatCatcher Statistics

Select this check box to collect the log data at a component level.

Global Variables

Global Variables

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

Usage rule

This component is generally used as an input component. An output component is required.

Related Scenario

For a scenario in which **tOpenbravoERPIInput** might be used, see *Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows* on page 2233.
tOpenbravoERPOutput

Writes data in an OpenbravoERP database.

tOpenbravoERPOutput writes an object in an OpenbravoERP database via the appropriate Web service.

tOpenbravoERPOutput Standard properties

These properties are used to configure tOpenbravoERPOutput running in the Standard Job framework.

The Standard tOpenbravoERPOutput component belongs to the Business family.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Openbravo REST Webservice URL</td>
<td>Enter the URL of the Web service that allows you to connect to the OpenbravoERP database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Action on data</td>
<td>From the list, select the one of the following actions: Update/Create or Remove</td>
</tr>
<tr>
<td>Use existing data file</td>
<td>Select this check box if desired and then select the file by browsing your directory.</td>
</tr>
<tr>
<td>Entity</td>
<td>Select the appropriate entity from the drop-down list.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_CREATED**: the number of rows created. This is an After variable and it returns an integer.
- **NB_LINE_REMOVED**: the number of rows removed. This is an After variable and it returns an integer.
- **NB_LINE_UNAUTHORIZED**: the number of rows unauthorized. This is an After variable and it returns an integer.
- **NB_LINE_FAILED**: the number of rows failed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

| Usage rule | This component is used as an output component. It requires an input component. |

### Related scenario

For a scenario in which **tOpenbravoERPOutput** may be used, see [Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows](#) on page 2233.
tOracleBulkExec

Offers gains in performance during operations performed on data of an Oracle database.

tOracleBulkExec inserts, appends, replaces or truncate data in an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tOracleBulkExec Standard properties

These properties are used to configure tOracleBulkExec running in the Standard Job framework.

The Standard tOracleBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version in use. |
| **Host**       | IP address of the database server. |
| **Port**       | Port number listening the database server. |
| **Database**   | Database name. |
| **Schema**     | Schema name. |

| **Username and Password** | DB user authentication data. |
|                         | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| **Table** | Name of the table to be written. Note that only one table can be written at a time. |

| **Action on table** | On the table defined, you can perform one of the following operations: |
|                     | **None**: No operation is carried out. |
|                     | **Drop and create table**: The table is removed and created again. |
|                     | **Create table**: The table does not exist and gets created. |
|                     | **Create table if not exists**: The table is created if it does not exist. |
|                     | **Drop table if exists and create**: The table is removed if it already exists and created again. |
|                     | **Clear table**: The table content is deleted. |
|                     | **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |

| **Data file name** | Name of the file to be loaded. |

**Warning:**
This file should be located on the same machine as the Jobserver.

| **Action on data** | On the data of the table defined, you can perform: |
**Insert**: Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.

**Update**: Update the existing data. You have to set the key on the schema if this option is selected.

**Append**: Append data to the table, whether the table is empty or not.

**Replace**: If the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.

**Truncate**: If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.

---

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

---

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Advanced separator (for number)</strong></th>
<th>Select this check box to change the separator used for the numbers.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing control file</strong></td>
<td>Select this check box if you use a control file (.ctl) and specify its path in the .ctl file name field.</td>
</tr>
<tr>
<td><strong>Record format</strong></td>
<td>Define the record format:</td>
</tr>
</tbody>
</table>
**Default**: format parameters are set by default.

**Stream**: set **Record terminator**.

**Fixed**: set the **Record length**.

**Variable**: set the **Field size of the record length**.

<table>
<thead>
<tr>
<th>Specify .ctl file’s INTO TABLE clause manually</th>
<th>Select this check box to manually fill in the <strong>INTO TABLE clause</strong> of the control file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Fields terminated by</strong></td>
<td>Character, string or regular expression to separate fields:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: no separator is used.</td>
</tr>
<tr>
<td></td>
<td><strong>Whitespace</strong>: the separator used is a space.</td>
</tr>
<tr>
<td></td>
<td><strong>EOF (used for loading LOBs from lobfile)</strong>: the separator used is an EOF character (End Of File).</td>
</tr>
<tr>
<td></td>
<td><strong>Other terminator</strong>: Set another terminator in the <strong>Field terminator</strong> field.</td>
</tr>
</tbody>
</table>

| **Use fields enclosure**                     | Select this check box if you want to use enclosing characters for the text:       |
|                                                 | **Fields enclosure (left part)**: character delimiting the left of the field.    |
|                                                 | **Field enclosure (right part)**: character delimiting the right of the field.   |

| **Use schema’s Date Pattern to load Date field** | Select this check box to use the date pattern of the schema in the date field. |

| **Specify field condition** | Select this check box to define data loading condition. |

| **Preserve blanks** | Select this check box to preserve the blanks. |

| **Trailing null columns** | Select this check box to load null columns. |

| **Load options** | Click + to add data loading options:        |
|                  | **Parameter**: select a loading parameter from the list. |
|                  | **Value**: enter a value for the parameter selected. |

| **NLS Language** | In the list, select the language used for the data that are not used in Unicode. |

| **Set Parameter NLS_TERRITORY** | Select this check box to modify the territory conventions used for day and weeks numbering. Your OS value is the default value used. |

| **Encoding** | Select the encoding from the list, or enter the encoding between double quotes if it does not exist in the list. This field is compulsory for database data handling. |

| **Output** | Select the type of output for the standard output of the Oracle database: |
|           | **to console**, |
|           | **to global variable**. |

| **Convert columns and table names to uppercase** | Select this check box to uppercase the names of the columns and the name of the table. |
**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE_DATA: the number of rows read. This is an After variable and it returns an integer.</th>

<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
<tr>
<td></td>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.</td>
</tr>
<tr>
<td></td>
<td>For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
The database server/client must be installed on the same machine where the Studio is installed or where the Job using `tOracleBulkExec` is deployed, so that the component functions properly.

**Truncating and inserting file data into an Oracle database**

This scenario describes how to truncate the content of an Oracle database and load the content of an input file. The related Job is composed of three components that respectively creates the content, output this content into a file to be loaded into the Oracle database after the database table has been truncated.

**Building the Job**

**Procedure**

1. Drop the following components: `tOracleInput`, `tFileOutputDelimited` and `tOracleBulkExec` from the Palette to the design workspace.
2. Connect the `tOracleInput` to the `tFileOutputDelimited` using a `Row > Main` link.
3. Connect the `tOracleInput` to the `tOracleBulkExec` using a `OnSubjobOk` trigger link.

**Results**

![Diagram showing the connection between components](image)

**Configuring the components**

**Procedure**

1. Double-click the `tOracleInput` to open its **Basic settings** view.
2. Define the Oracle connection details. It is recommended to store the database connection details in the **Metadata** folder of the **Repository** tree view in order to retrieve them easily at any time in any Job.
3. Define the schema, if it is not stored in the **Repository**. In this example, the schema contains four columns as follows: *ID_Contract, ID_Client, Contract_type* and *Contract_Value*.

4. Define the **tFileOutputDelimited** component parameters, including output File Name, Row separator and Fields delimiter.

5. Double-click on the **tOracleBulkExec** to define the database populating properties.

6. In the **Property Type** list, select **Repository** if you stored the database connection details under the Metadata node of the **Repository** or select **Built-in** to define them manually. In this scenario, use the **Built-in** mode.

7. Set the connection parameters in the following fields: **Host, Port, Database, Schema, Username**, and **Password**.

8. Fill in the name of the **Table** to be populated and the **Action on data** to be carried out. In this use case, select **insert**.

9. In the **Schema** list, select **Built-in**, and click the [...] button next to the **Edit schema** field to define the structure of the data to be passed to the next component.

10. Click the **Advanced settings** view to configure the advanced settings of the component.
11. Select the **Use an existing control file** check box if you want to use a control file (.ctl) storing the status of the physical structure of the database. Or, fill in the following fields manually: **Record format**, **Specify .ctl file's INTO TABLE clause manually**, **Field terminated by**, **Use fields enclosure**, **Use schema's Date Pattern to load Date field**, **Specify field condition**, **Preserve blanks**, **Trailing null columns**, **Load options**, **NLS Language** and **Set Parameter NLS_TERRITORY** according to your database.

12. In the **Encoding** list, select the encoding, or enter the encoding between double quotes if it does not exist in the list.

13. In the **Output** list, select to console to output the standard output of the database in the console.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** to run the Job. The log is shown in the console of the **Run** view and the table is populated with the parameter file data.

### Results

Related topic: see **Inserting data in bulk in MySQL database** on page 2515.
tOracleClose

Closes the transaction committed in the connected Oracle database.

**tOracleClose Standard properties**

These properties are used to configure tOracleClose running in the Standard Job framework.

The Standard tOracleClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the connection component of interest if more than one connection is planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Oracle components, especially with tOracleConnection and tOracleCommit.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Related scenarios

No scenario is available for the Standard version of this component yet.
tOracleCommit

Validates the data processed through the Job into the connected Oracle database

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tOracleCommit Standard properties

These properties are used to configure tOracleCommit running in the Standard Job framework.

The Standard tOracleCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Warning:
If you want to use a Row > Main connection to link tOracleCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tOracle* components, especially with the tOracleConnection and tOracleRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For tOracleCommit related scenario, see Inserting data in mother/daughter tables on page 2452
tOracleConnection

Opens a connection to the specified Oracle database for reuse in the subsequent subJob or subJobs.

**tOracleConnection Standard properties**

These properties are used to configure tOracleConnection running in the Standard Job framework.

The Standard tOracleConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>

</tr>
<tr>
<td><strong>KeyStore password</strong></td>
</tr>
<tr>
<td><strong>Disable CBC protection</strong></td>
</tr>
</tbody>
</table>
**tOracleConnection**

This property is available only when the **Use SSL** check box is selected.

### Additional JDBC parameters

Specify additional connection properties for the DB connection you are creating.

**Note:**
You can set the encoding parameters through this field.

### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

### Advanced settings

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics

Select this check box to gather the job processing metadata at a Job level as well as at each component level.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is more commonly used with other tOracle* components,</td>
</tr>
<tr>
<td>especially with the tOracleCommit and tOracleRollback components.</td>
</tr>
</tbody>
</table>

Related scenario

For tOracleConnection related scenario, see tMysqlConnection on page 2451
tOracleInput

Reads an Oracle database and extracts fields based on a query.
tOracleInput executes a database query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

tOracleInput Standard properties

These properties are used to configure tOracleInput running in the Standard Job framework.
The Standard tOracleInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file where the properties are stored.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Oracle OCI</strong>: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td></td>
<td><strong>Oracle Custom</strong>: Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td></td>
<td><strong>Oracle Service Name</strong>: Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td></td>
<td><strong>WALLET</strong>: Select this connection type to store credentials in an Oracle wallet.</td>
</tr>
<tr>
<td></td>
<td><strong>Oracle SID</strong>: Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version in use. |
| **Host** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database. |

| **Oracle schema** | Oracle schema name. |

| **Username and Password** | DB user authentication data. |
|                          | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
|                          | Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: |
|                          | • **View schema**: choose this option to view the schema only. |
|                          | • **Change to built-in property**: choose this option to change the schema to Built-in for local changes. |
|                          | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |

| **Built-In** | You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |
| **Table name** | Database table name. |
| **Query type and Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
| **Specify a data source alias** | Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified. This check box is not available when the Use an existing connection check box is selected. |

**Advanced settings**

| **Additional JDBC parameters** | Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, encryption=1;clientname=Talend. This field is not available if the Use an existing connection check box is selected. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |
| **Use cursor** | Select this check box and in the Cursor size field displayed, specify the number of rows to fetch in one go from the database. The performance can be improved by tuning this fetch size to an appropriate value. |
| **Trim all the String/Char columns** | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| **Trim column** | Remove leading and trailing whitespace from defined columns. |
| **No null values** | Check this box to improve the performance if there are no null values. |

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer. **QUERY**: the query statement being processed. This is a Flow variable and it returns a string. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Oracle databases.</th>
</tr>
</thead>
</table>

### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

## Using context parameters when reading a table from an Oracle database

In this scenario, we will read a table from an Oracle database using a context parameter to refer to the table name.
Dropping and linking the components

Procedure

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a tOracleInput component and a tLogRow component.
2. Connect tOracleInput to tLogRow using a Row > Main link.

Configuring the components

Procedure

1. Double-click tOracleInput to open its Basic Settings view in the Component tab.

2. Select a connection type from the Connection Type drop-down list. In this example, it is Oracle SID.

Select the version of the Oracle database to be used from the DB Version drop-down list. In this example, it is Oracle 12-7.

In the Host field, enter the Oracle database server’s IP address. In this example, it is 192.168.31.32.

In the Database field, enter the database name. In this example, it is TALEND.
In the **Oracle schema** field, enter the Oracle schema name. In this example, it is **TALEND**.
In the **Username** and **Password** fields, enter the authentication details.

3. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema of tOracleInput_1](image)

4. Click the [+ ] button to add four columns: **ID** and **AGE** of the integer type, **NAME** and **SEX** of the string type.
   
   Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. Put the cursor in the **Table Name** field and press **F5** for context parameter setting. The dialog box **New Context Parameter** pops up.

![New Context Parameter](image)

For more information about context settings, see *Talend Studio User Guide*. 

---

2732
6. In the **Name** field, enter the context parameter name. In this example, it is *TABLE*.
In the **Default value** field, enter the name of the Oracle database table to be queried. In this example, it is *PERSON*.

7. Click **Finish** to validate the setting.
   The context parameter *context.TABLE* automatically appears in the **Table Name** field.

8. In the **Query Type** list, select **Built-In**. Then, click **Guess Query** to get the query statement.

```
"SELECT
  +context.TABLE+."ID",
  +context.TABLE+.NAME,
  +context.TABLE+.SEX,
  +context.TABLE+.AGE
FROM +context.TABLE
```

9. Double-click **tLogRow** to open its **Basic settings** view in the **Component** tab.

10. In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```
[statistics] connecting to socket on port 3750
[statistics] connected

<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>

[statistics] disconnected
```

As shown above, the data in the Oracle database table *PERSON* is displayed on the console.

### Related scenarios

For related scenarios, see:
• Reading data from different MySQL databases using dynamically loaded connection parameters on page 495.
tOracleOutput

Writes, updates, makes changes or suppresses entries in an Oracle database.

tOracleOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tOracleOutput Standard properties**

These properties are used to configure tOracleOutput running in the Standard Job framework. The Standard tOracleOutput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>![Database Connection Icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view.</td>
</tr>
<tr>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>WALLET</strong></td>
<td>Select this connection type to store credentials in an Oracle wallet.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version in use. |
| **Host**       | Database server IP address. |
| **Port**       | Listening port number of DB server. |
| **Database**   | Name of the database. |
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Table**      | Name of the table to be written. Note that only one table can be written at a time. |
| **Action on table** | **Note:**  
The **Action on table** list will not be available if you select the **Enable parallel execution** check box in the **Advanced settings** view.  
On the table defined, you can perform one of the following operations:  
**Default:** No operation is carried out. |
<table>
<thead>
<tr>
<th>Action on data</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Drop and create table:</strong> The table is removed and created again.</td>
</tr>
<tr>
<td><strong>Create table:</strong> The table does not exist and gets created.</td>
</tr>
<tr>
<td><strong>Create table if not exists:</strong> The table is created if it does not exist.</td>
</tr>
<tr>
<td><strong>Drop table if exists and create:</strong> The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td><strong>Clear table:</strong> The table content is deleted.</td>
</tr>
<tr>
<td><strong>Truncate table:</strong> The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>Truncate table with reuse storage:</strong> The table content is deleted. You do not have the possibility to rollback the operation. However, it is allowed to reuse the existing storage allocated to the table though the storage is considered empty.</td>
</tr>
<tr>
<td><strong>Warning:</strong> If you select the <strong>Use an existing connection</strong> check box and select an option other than <strong>Default</strong> from the <strong>Action on table</strong> list, a commit statement will be generated automatically before the data insert/update/delete operation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action on data</strong></td>
</tr>
<tr>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td><strong>Insert:</strong> Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td><strong>Update:</strong> Make changes to existing entries</td>
</tr>
<tr>
<td><strong>Insert or update:</strong> Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td><strong>Update or insert:</strong> Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td><strong>Delete:</strong> Remove entries corresponding to the input flow.</td>
</tr>
<tr>
<td><strong>Warning:</strong> It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking <strong>Edit Schema</strong> and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the <strong>Advanced settings</strong> view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the <strong>Use field options</strong> check box and then in the <strong>Key in update column</strong>, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the <strong>Key in delete column</strong> for the Delete operation.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit schema</strong></td>
</tr>
<tr>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either <strong>Built-in</strong> or stored remotely in the <strong>Repository</strong>.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Built-In</th>
<th>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
</table>
| Repository | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

**Die on error**  
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Specify a data source alias**  
Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.  
If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.  
This check box is not available when the **Use an existing connection** check box is selected.

**Advanced settings**

**Additional JDBC parameters**  
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the **Basic settings**.
| **Commit every** | Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |
| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.  

- **Name**: Type in the name of the schema column to be altered or inserted as new column.  
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.  
- **Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.  
- **Reference column**: Type in a column of reference that the tDBOutput can use to place or replace the new or altered column. |
| **Use field options** | Select this check box to customize a request, especially when there is double action on data. |
| **Use Hint Options** | Select this check box to activate the hint configuration area which helps you optimize a query’s execution. In this area, parameters are:  
- **HINT**: specify the hint you need, using the syntax /*+ */.  
- **POSITION**: specify where you put the hint in a SQL statement.  
- **SQL STMT**: select the SQL statement you need to use. |
| **Convert columns and table to uppercase** | Select this check box to set the names of columns and table in upper case. |
| **Enable debug mode** | Select this check box to display each step during processing entries in a database. |
| **Use Batch** | Select this check box to activate the batch mode for data processing. |
| **Batch Size** | Specify the number of records to be processed in each batch.  
This field appears only when the **Use batch mode** check box is selected. |
**Support null in "SQL WHERE" statement**

Select this check box to validate null in "SQL WHERE" statement.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>QUERY: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

### Usage

#### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Oracle database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMysqlOutput** in use, see **Retrieving data in error with a Reject link** on page 2500.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic**
connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For tOracleOutput related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2492.
tOracleOutputBulk

Writes a file with columns based on the defined delimiter and the Oracle standards.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tOracleOutputBulk Standard properties

These properties are used to configure tOracleOutputBulk running in the Standard Job framework.

The Standard tOracleOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td>Warning: This file is generated on the local machine or a shared folder on the LAN.</td>
<td></td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
</tbody>
</table>
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

---

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

| Advanced separator (for number) | Select this check box to change data separators for numbers:  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Thousand separator</td>
<td>define separators you want to use for thousands.</td>
</tr>
<tr>
<td>Decimal separator</td>
<td>define separators you want to use for decimals.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Field separator</th>
<th>Character, string or regular expression to separate fields.</th>
</tr>
</thead>
</table>
| Row separator                   | String (ex: 
\n on Unix) to separate rows.                             |
| Encoding                        | Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling. |
| Bulk file parameters            | Set the parameters **Buffer Size** and **StringBuilder Size** for a performance gain according to the memory size. |
| tStatCatcher Statistics         | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

### Global Variables

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with <strong>tOracleBulkExec</strong> component. Used together they offer gains in performance while feeding a Oracle database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/Oracle</td>
</tr>
</tbody>
</table>

### Related scenarios

For use cases in relation with **tOracleOutputBulk**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tOracleOutputBulkExec

Executes the Insert action in the specified Oracle database.

As a dedicated component, it allows gains in performance during Insert operations to an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component.

tOracleOutputBulkExec Standard properties

These properties are used to configure tOracleOutputBulkExec running in the Standard Job framework.

The Standard tOracleOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<td></td>
</tr>
<tr>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
<td></td>
</tr>
</tbody>
</table>

**File Name**
Name of the file to be generated and loaded.

**Warning:**
This file is generated on the machine specified by the URI in the Host field so it should be on the same machine as the database server.

**Create directory if not exists**
This check box is selected by default. It creates a directory to hold the output table if required.

**Append**
Select this check box to add the new rows at the end of the file.

**Action on data**
On the data of the table defined, you can perform:

- **Insert**: Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.
- **Update**: Update the existing data. You have to set the key on the schema if this option is selected.
- **Append**: Append data to the table, whether the table is empty or not.
- **Replace**: if the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.
- **Truncate**: If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.

**Schema and Edit Schema**
A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon
Built-In: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide.*

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide.*

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

**Field separator**

Character, string or regular expression to separate fields.

### Advanced settings

| Advanced separator (for number) | Select this check box to change data separators for numbers:  
| **Thousands separator:** define separators you want to use for thousands.  
| **Decimal separator:** define separators you want to use for decimals.  
| Use existing control file | Select this check box and browse to the .ctl control file you want to use.  
| Field separator | Character, string or regular expression to separate fields.  
| Row separator | String (ex: \n on Unix) to separate rows.  
| Specify .ctl file’s INTO TABLE clause manually | Select this check box to enter manually the INTO TABLE clause of the control file directly into the code.  
| Use schema’s Date Pattern to load Date field | Select this check box to use the date model indicated in the schema for dates.  
| Specify field condition | Select this check box to define a condition for loading data.  
| Preserve blanks | Select this check box to preserve blank spaces.  
| Trailing null columns | Select this check box to load data with all empty columns.  
| Load options | Click + to add data loading options:  
| **Parameter:** select a loading parameter from the list.  
| **Value:** enter a value for the parameter selected.  
| NLS Language | From the drop-down list, select the language for your data if the data is not in Unicode. |
Set Parameter NLS_TERRITORY

Select this check box to modify the conventions used for date and time formats. The default value is that of the operating system.

Encoding

Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

Oracle encoding type

Select the Oracle-specific encoding type for the data to be processed. This encoding type allows tOracleOutputBulkExec to properly generate the Sybase Bulk command.

Output

Select the type of output for the standard output of the Oracle database:
- to console,
- to global variable.

Convert columns and table names to uppercase

Select this check box to put columns and table names in upper case.

Bulk file parameters

Set the parameters Buffer Size and StringBuilder Size for a performance gain according to the memory size.

tStatCatcher Statistics

Select this check box to gather the job processing metadata at a job level as well as at each component level.

Usage

Usage rule

This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

The database server/client must be installed on the same machine where the Studio is installed or where the Job using tOracleOutputBulkExec is deployed, so that the component functions properly.
Related scenarios

For use cases in relation with tOracleOutputBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tOracleRollback

Cancels the transaction commit in the connected Oracle database to avoid committing part of a transaction involuntarily.

tOracleRollback Standard properties

These properties are used to configure tOracleRollback running in the Standard Job framework.
The Standard tOracleRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tOracle* components, especially with the tOracleConnection and tOracleCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection. |
Related scenario

For tOracleRollback related scenario, see tMysqlRollback on page 2517
tOracleRow

Executes the stated SQL query on the specified Oracle database.

Depending on the nature of the query and the database, tOracleRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tOracleRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tOracleRow Standard properties**

These properties are used to configure tOracleRow running in the Standard Job framework.

The Standard tOracleRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version in use. |
| **Host**       | Database server IP address. |
| **Port**       | Listening port number of DB server. |
| **Database**   | Name of the database. |

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

**Query type**

Either Built-in or Repository.

**Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.
**Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Query**
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Use NB_LINE_**
This option allows you feed the variable with the number of rows inserted/updated/deleted to the next component or subjob. This field only applies if the query entered in **Query** field is a INSERT, UPDATE or DELETE query.

- **NONE:** does not feed the variable.
- **INSERTED:** feeds the variable with the number of rows inserted.
- **UPDATED:** feeds the variable with the number of rows updated.
- **DELETED:** feeds the variable with the number of rows deleted.

**Specify a data source alias**
Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

**Die on error**
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

**Advanced settings**

**Propagate QUERY’s recordset**
Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.

**Note:**
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

**Use PreparedStatement**
Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by "?" in the SQL instruction of the **Query** field in the Basic Settings tab.

**Parameter Index:** Enter the parameter position in the SQL instruction.
Parameter Type: Enter the parameter type.
Parameter Value: Enter the parameter value.

Note:
This option is very useful if you need to execute the same query several times. Performance levels are increased. You can also use PreparedStatement to avoid SQL injection. For a detailed scenario of utilizing this feature, see Using PreparedStatement objects to query data on page 2524.

Commit every
Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

Global Variables
QUERY: the query statement being processed. This is a Flow variable and it returns a string.
NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.
NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.
NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage
This component offers the flexibility of the DB query and covers all possible SQL queries.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenarios**

For related topics, see:

- Combining two flows for selective output on page 2529
- Procedure on page 635.
- Removing and regenerating a MySQL table index on page 2523.
- Using PreparedStatement objects to query data on page 2524.
**tOracleSCD**

Reflects and tracks changes in a dedicated Oracle SCD table.

**tOracleSCD Standard properties**

These properties are used to configure tOracleSCD running in the Standard Job framework.

The Standard tOracleSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

<table>
<thead>
<tr>
<th><strong>Basic settings</strong></th>

</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>Drop-down list of available drivers:</td>
</tr>
<tr>
<td><strong>Oracle OCI</strong>: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
</tbody>
</table>
### Oracle Service Name
Select this connection type to use the TNS alias that you give when you connect to the remote database.

### Oracle SID
Select this connection type to uniquely identify a particular database on a system.

### Oracle Custom
Select this connection type to access a clustered database.

| **DB Version** | Select the Oracle version you are using. |
| **Host** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database. |
| **Schema** | Name of the DB schema. |

| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |

| **Action on table** | Select to perform one of the following operations on the table defined:  
- None: No action is carried out on the table.  
- Create table: A new table is created.  
- Create table if not exists: A table is created if it does not exist. |

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |

| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

**SCD Editor**

The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see *SCD management methodology* on page 2537.

**Use memory saving Mode**

Select this check box to maximize system performance.

**Source keys include Null**

Select this check box to allow the source key columns to have Null values.

**Warning:**

Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**Additional JDBC parameters**

Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the *Use an existing connection* check box in the Basic settings.

**End date time details**

Specify the time value of the SCD end date time setting in the format of *HH:mm:ss*. The default value for this field is 12:00:00. This field appears only when SCD Type 2 is used and *Fixed year value* is selected for creating the SCD end date.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Debug mode**

Select this check box to display each step during processing entries in a database.

### Global Variables

**Global Variables**

- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

### Related scenario

For related scenarios, see tMysqlSCD on page 2534.
tOracleSCDELT

Reflects and tracks changes in a dedicated Oracle SCD table through SQL queries.

tOracleSCDELT addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Oracle SCD table.

**tOracleSCDELT Standard properties**

These properties are used to configure tOracleSCDELT running in the Standard Job framework.

The Standard tOracleSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
**Oracle OCI:** Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.

**Oracle Service Name:** Select this connection type to use the TNS alias that you give when you connect to the remote database.

**Oracle SID:** Select this connection type to uniquely identify a particular database on a system.

**Oracle Custom:** Select this connection type to access a clustered database.

| **DB Version** | Select the Oracle version you are using. |
| **Host** | The IP address of the database server. |
| **Port** | Listening port number of database server. |
| **Database** | Name of the database |
| **Username and Password** | User authentication data for a dedicated database. |
| | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Source table** | Name of the input DB2 SCD table. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | Select to perform one of the following operations on the table defined: |
| | **None:** No action carried out on the table. |
| | **Drop and create table:** The table is removed and created again |
| | **Create table:** A new table gets created. |
| | **Create table if not exists:** A table gets created if it does not exist. |
| | **Clear table:** The table content is deleted. You have the possibility to rollback the operation. |
| | **Truncate table:** The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields. |
| | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: |
| | • **View schema:** choose this option to view the schema only. |
| | • **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes. |
| | • **Update repository connection:** choose this option to change the schema stored in the repository and... |
| **Surrogate Key** | Select the surrogate key column from the list. |
| **Creation** | Select the method to be used for the surrogate key generation.  
For more information regarding the creation methods, see SCD management methodology on page 2537. |
| **Source Keys** | Select one or more columns to be used as keys, to ensure the unicity of incoming data. |
| **Source fields value include Null** | Select this check box to allow the source columns to have Null values.  
**Note:**  
The source columns here refer to the fields defined in the SCD type 1 fields and SCD type 2 fields tables. |
| **Use SCD Type 1 fields** | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes. |
| **Use SCD Type 2 fields** | Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.  
**Start date:** Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table.  
**End Date:** Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select Fixed Year value and fill it in with a fictive year to avoid having a null value in the End Date field.  
**Note:** To avoid duplicated change records, it is recommended to select a column that can identify each change for this field.  
**Log Active Status:** Adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record.  
**Log versions:** Adds a column to your SCD schema to hold the version number of the record. |

**Built-in:** The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.  
**Repository:** The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1874.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3060.
**tOracleSP**

Calls an Oracle database stored procedure.

tOracleSP offers a convenient way to centralize multiple or complex queries in a database and call them easily.

**tOracleSP Standard properties**

These properties are used to configure tOracleSP running in the Standard Job framework.

The Standard tOracleSP component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td>Oracle OCI</td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td>Oracle Service Name</td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td>Oracle SID</td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td>Oracle Custom</td>
<td>Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>--------------------</td>
<td>--------------------------------</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the Oracle version in use.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>

<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td>SP Name</td>
<td>Type in the exact name of the Stored Procedure (or Function)</td>
</tr>
<tr>
<td>Is Function / Return result in</td>
<td>Select this check box, if the stored procedure is a function and one value only is to be returned.</td>
</tr>
<tr>
<td></td>
<td>Select on the list the schema column, the value to be returned is based on.</td>
</tr>
</tbody>
</table>
Click the Plus button and select the various **Schema Columns** that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.

<table>
<thead>
<tr>
<th>Parameters</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Select the <strong>Type</strong> of parameter:</td>
</tr>
<tr>
<td></td>
<td><strong>IN</strong>: Input parameter.</td>
</tr>
<tr>
<td></td>
<td><strong>OUT</strong>: Output parameter/return value.</td>
</tr>
<tr>
<td></td>
<td><strong>IN OUT</strong>: Input parameter is to be returned as value, likely after modification through the procedure (function).</td>
</tr>
<tr>
<td></td>
<td><strong>RECORDSET</strong>: Input parameters is to be returned as a set of values, rather than single value.</td>
</tr>
</tbody>
</table>

**Note:**
Check Inserting data in mother/daughter tables on page 2452 if you want to analyze a set of records from a database table or DB query and return single records.

The **Custom Type** is used when a **Schema Column** you want to use is user-defined. Two **Custom Type** columns are available in the **Parameters** table. In the first **Custom Type** column:
- Select the check box in the **Custom Type** column when the corresponding **Schema Column** you want to use is of user-defined type.
- If all listed **Schema Columns** in the **Parameters** table are of custom type, you can select the check box before **Custom Type** once for them all.

Select a database type from the **DB Type** list to map the source database type to the target database type:
- **Auto-Mapping**: Map the source database type to the target database type automatically (default).
- **CLOB**: Character large object.
- **BLOB**: Binary large object.
- **DECIMAL**: Decimal numeric object.
- **NUMERIC**: Character 0 to 9.
- **XMLTYPE**: XML schema type.

**Warning:**
When mapping a column selected from the **Return result** in list box or set to the IN or OUT type of parameter to **XMLTYPE**, make sure that the column is of type String in the schema.

In the second **Custom Type** column, you can precise what the custom type is. The type may be:
- **STRUCT**: used for one element.
- **ARRAY**: used for a collection of elements.

In the **Custom name** column, specify the name of the custom type that you have given to this type.
Warning:
When an OUT parameter uses the custom type, make sure that its corresponding Schema Column has chosen the Object type in the schema table.

Specify a data source alias
Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

Advanced settings

Additional JDBC parameters
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.

NLS Language
In the list, select the language used for the data that are not used in Unicode.

NLS Territory
Select the conventions used for date and time formats. The default value is that of the operating system.

tStatCatcher Statistics
Select this check box to gather the job processing metadata at a Job level as well as at each component level.

Usage

Usage rule
This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.

Dynamic settings
Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation
The Stored Procedures syntax should match the Database syntax.
Checking number format using a stored procedure

The following job aims at connecting to an Oracle Database containing Social Security Numbers and their holders' name, calling a stored procedure that checks the SSN format against a standard ###-##-#### format. Then the verification output results, 1 for valid format and 0 for wrong format get displayed onto the execution console.

- Drag and drop the following components from the Palette: tOracleConnection, tOracleInput, tOracleSP and tLogRow.
- Link the tOracleConnection to the tOracleInput using a Then Run connection as no data is handled here.
- And connect the other components using a Row Main link as rows are to be passed on as parameter to the SP component and to the console.
- In the tOracleConnection, define the details of connection to the relevant Database. You will then be able to reuse this information in all other DB-related components.
- Then select the tOracleInput and define its properties.
  - Select the Use an existing connection check box and select the tOracleConnection component in the list in order to reuse the connection details that you already set.
  - Select Repository as Property type as the Oracle schema is defined in the DB Oracle connection entry of the Repository. If you haven’t recorded the Oracle DB details in the Repository, then fill in the Schema name manually.
• Then select **Repository** as **Schema**, and retrieve the relevant schema corresponding to your Oracle DB table.

<table>
<thead>
<tr>
<th></th>
<th>ID</th>
<th>NAME</th>
<th>CITY</th>
<th>SSNUMBER</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>Jack</td>
<td>LA</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>2</td>
<td>2</td>
<td>Tom</td>
<td>NYC</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>3</td>
<td>3</td>
<td>Bill</td>
<td>SF</td>
<td>123=45-6789</td>
</tr>
<tr>
<td>4</td>
<td>4</td>
<td>Jana</td>
<td>NYC</td>
<td>236-52-2955</td>
</tr>
<tr>
<td>5</td>
<td>5</td>
<td>Brandon</td>
<td>SLC</td>
<td>561-52-B267</td>
</tr>
</tbody>
</table>

• In this example, the SSN table has a four-column schema that includes *ID*, *NAME*, *CITY* and *SSNUMBER*.

• In the **Query** field, type in the following Select query or select it in the list, if you stored it in the Repository.

  ```sql
  select ID, NAME, CITY, SSNUMBER from SSN
  ```

• Then select the **tOracleSP** and define its **Basic settings**.

  ![Parameter grid](image)

  - **Use an existing connection**
  - **Component list**
  - **Schema**
  - **SP Name**
  - **Is function**
  - **DBType**
  - **Parameter**

• Like for the **tOracleInput** component, select **Repository** in the **Property type** field and select the **Use an existing connection** check box, then select the relevant entries in the respective list.

• The schema used for the **tOracleSP** slightly differs from the input schema. Indeed, an extra column (*SSN_Valid*) is added to the Input schema. This column will hold the format validity status (1 or 0) produced by the procedure.

• In the **SP Name** field, type in the exact name of the stored procedure (or function) as called in the Database. In this use case, the stored procedure name is *is_ssn*. 

2772
• The basic function used in this particular example is as follows:

```
CREATE OR REPLACE FUNCTION is_ssn(string_in VARCHAR2)
RETURN PLS_INTEGER
IS
  -- validating ###-##-#### format
BEGIN
  IF TRANSLATE(string_in, '0123456789A', 'AAAAAAAAAAB') = 'AAA-AA-AAAA' THEN
    RETURN 1;
  END IF;
  RETURN 0;
END is_ssn;
/
```

• As a return value is expected in this use case, the procedure acts as a function, so select the Is function check box.

• The only return value expected is based on the ssn_valid column, hence select the relevant list entry.

• In the Parameters area, define the input and output parameters used in the procedure. In this use case, only the SSNNumber column from the schema is used in the procedure.

• Click the plus sign to add a line to the table and select the relevant column (SSNNumber) and type (IN).

• Then select the tLogRow component and click Sync Column to make sure the schema is passed on from the preceding tOracleSP component.

• Select the Print values in cells of a table check box to facilitate the output reading.

• Then save your job and press F6 to run it.

On the console, you can read the output results. All input schema columns are displayed even though they are not used as parameters in the stored procedure.

The final column shows the expected return value, whether the SS Number checked is valid or not.

Note:

Check Inserting data in mother/daughter tables on page 2452 if you want to analyze a set of records from a database table or DB query and return single records.
Related scenarios

For related scenarios, see:

- Retrieving personal information using a stored procedure on page 2430.
- Using tMysqlSP to find a State Label using a stored procedure on page 2554.
- Executing a stored procedure using tMDMSP on page 2174.
tOracleTableList

Lists the names of specified Oracle tables using a SELECT statement based on a WHERE clause. tOracleTableList iterates on a set of tables through a defined Oracle connection.

**tOracleTableList Standard properties**

These properties are used to configure tOracleTableList running in the Standard Job framework.
The Standard tOracleTableList component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection is planned for the current Job.</td>

</table>

Related scenarios

For a **tOracleTableList** related scenario, see Iterating on DB tables and deleting their content using a user-defined SQL template on page 2559.
### tPaloCheckElements

Checks whether elements are present in an incoming data flow existing in a given cube.

This component can be used along with tPaloOutputMulti. It checks if the elements from the input stream exist in the given cube, before writing them. It can also define a default value to be used for nonexistent elements.

### tPaloCheckElements Standard properties

These properties are used to configure tPaloCheckElements running in the Standard Job framework.

The Standard tPaloCheckElements component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</td>

</tr>
<tr>
<td></td>
<td>- Stop: the entire process is interrupted.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>

2777
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.

Define the elements to be checked in the table provided.
- **Column**: shows the column(s) from the input schema. It is completed automatically once a schema is retrieved or created.
- **Element type**: select the element type for the input column. Only one column can be defined as Measure.
- **Default**: type in the default value to be used if you have selected the Use default option in the On element error field.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data on the component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component requires an input component. |

### Related scenario
For related scenarios, see *Creating a dimension with elements* on page 2802.

### Limitation
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
tPaloCube

Performs operations on a given Palo cube.

This component creates, deletes or clears Palo cubes from existing dimensions in a Palo database.

**tPaloCube Standard properties**

These properties are used to configure tPaloCube running in the Standard Job framework.
The Standard tPaloCube component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Host Name | Enter the host name or the IP address of the host server. |
| Server Port | Type in the listening port number of the Palo server. |
| Username and Password | Enter the Palo user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database | Type in the name of the database in which the operation is to take place. |
| Cube | Type in the name of the cube where the operation is to take place. |
| Cube type | From the drop-down list, select the type of cube on which the operation is to be carried out:
- **Normal**: this is the normal and default type of cube.
- **Attribute**: an Attribute cube is created with a normal cube.
- **User Info**: User Info cubes can be created/modified with this component. |
| Action on cube | Select the operation you want to carry out on the cube defined:
- **Create cube**: the cube does not exist and will be created.
- **Create cube if not exists**: the cube is created if it does not exist.
- **Delete cube if exists and create**: the cube is deleted if it already exists and a new one will be created.
- **Delete cube**: the cube is deleted from the database. |
### Dimension list

Add rows and enter the name of existing database dimension's to be used in the cube. The order of the dimensions in the list determines the order of the dimensions created.

### Advanced settings

#### tStat Catcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **CUBENAME**: the name of the cube. This is an After variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

**Usage rule**

Can be used as a standalone component for dynamic cube creation with a defined dimension list.

**Connections**

- **Outgoing links (from this component to another):**
  - **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

- **Incoming links (from one component to this one):**
  - **Row**: Iterate
  - **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

**Limitation**

- The cube creation process does not create dimensions from scratch, so the dimensions to be used in the cube must be created beforehand.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can
Creating a cube in an existing database

The Job in this scenario creates a new two dimensional cube in the Palo demo database *Biker*.

To replicate this scenario, proceed as follows:

**Configuring the tPaloCube component**

**Procedure**

1. Drop **tPaloCube** from the **Palette** onto the design workspace.
2. Double-click **tPaloCube** to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

6. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

7. In the **Cube** field, type in the name you want to use for the cube to be created, for example, *bikerTalend*.

8. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

9. In the **Action on cube** field, select the action to be performed. In this scenario, select **Create cube**.

10. Under the **Dimension list** table, click the plus button twice to add two rows into the table.

11. In the **Dimension list** table, type in the name for each newly added row to replace the default row name. In this scenario, type in *Months* for the first row and *Products* for the second. These two dimensions exist already in the Biker database where the new cube will be created.

**Job execution**

Press **F6** to run the Job.

A new cube has been created in the *Biker* database and the two dimensions are added into this cube.
tPaloCubeList

Retrieves a list of cube details from the given Palo database.
This component lists cube names, cube types, number of assigned dimensions, the number of filled
cells from the given database.

Discovering the read-only output schema of tPaloCubeList

The below table presents information related to the read-only schema of the tPaloCubeList
component.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Cube_id</td>
<td>int</td>
<td>Internal id of the cube.</td>
</tr>
<tr>
<td>Cube_name</td>
<td>string</td>
<td>Name of the cube.</td>
</tr>
<tr>
<td>Cube_dimensions</td>
<td>int</td>
<td>Number of dimensions inside the cube.</td>
</tr>
<tr>
<td>Cube_cells</td>
<td>long</td>
<td>Number of calculated cells inside the cube.</td>
</tr>
<tr>
<td>Cube_filled_cells</td>
<td>long</td>
<td>Number of filled cells inside the cube.</td>
</tr>
<tr>
<td>Cube_status</td>
<td>int</td>
<td>Status of the cube. It may be:</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 0: unloaded</td>
</tr>
<tr>

</tbody>
</table>

tPaloCubeList Standard properties

These properties are used to configure tPaloCubeList running in the Standard Job framework.
The Standard tPaloCubeList component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

<table>
<thead>
<tr>
<th><strong>Host Name</strong></th>
<th>Enter the host name or the IP address of the host server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Server Port</strong></td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Type in the name of the database whose cube details you want to retrieve.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_CUBES**: the number of cubes. This is an After variable and it returns an integer.  
**CUBEID**: the ID of the cube. This is a Flow variable and it returns an integer.  
**CUBENAME**: the name of the cube. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| **Usage rule** | This component can be used as a start component. It requires an output component. |
| **Connections** | Outgoing links (from this component to another):  
**Row**: Main, Iterate;  
**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |
### Limitation

The output schema is fixed and read-only. Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

---

## Retrieving detailed cube information from a given database

The Job in this scenario retrieves detailed information of the cubes pertaining to the demo Palo database, *Biker*.

To replicate this scenario, proceed as follows:

### Setting up the Job

**Procedure**

1. Drop tPaloCubeList and tLogRow from the component Palette onto the design workspace.
2. Right-click tPaloCubeList to open the contextual menu.
3. From this menu, select Row > Main to link the two components.

### Configuring the tPaloCube component

**Procedure**

1. Double-click the tPaloCube component to open its Component view.
2. In the Host name field, type in the host name or the IP address of the host server, localhost for this example.

3. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the Username field and the Password field, type in the authentication information. In this example, both of them are admin.

5. In the Database field, type in the database name in which you want to create the cube, Biker in this example.

Job execution

Press F6 to run the Job.

The cube details are retrieved from the Biker database and are listed in the console of the Run view.

```

### Creating a database

The Job in this scenario creates a new database on a given Palo server.
To replicate this scenario, proceed as follows:

**Procedure**

1. Drop `tPaloDatabase` from the component `Palette` onto the design workspace.
2. Double-click the `tPaloDatabase` component to open its `Component` view.

![tPaloDatabase component](image)

3. In the **Host name** field, type in the host name or the IP address of the host server, `localhost` for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.
6. In the **Database** field, type in the database name in which you want to create the cube, `talenddatabase` in this example.
7. In the **Action on database** field, select the action to be performed. In this scenario, select **Create database** as the database to be created does not exist.
8. Press **F6** to run the Job.

**Results**

A new database is created on the given Palo server.
tPaloDatabaseList

Lists database names, database types, number of cubes, number of dimensions, database status and database id from a given Palo server.

The tPaloDatabaseList retrieves a list of database details from the given Palo server.

**Discovering the read-only output schema of tPaloDatabaseList**

The below table presents information related to the read-only output schema of the tPaloDatabaseList component.

<table>

**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. For further information regarding connections, see Talend Studio User Guide. |
Retrieving detailed database information from a given Palo server

The Job in this scenario retrieves details of all of the databases from a given Palo server.

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop `tPaloDatabaseList` and `tLogRow` from the component Palette onto the design workspace.
2. Right-click `tPaloDatabaseList` to open the contextual menu.
3. From this menu, select `Row > Main` to link the two components.

**Configuring the tPaloDatabaseList component**

**Procedure**

1. Double-click the `tPaloDatabaseList` component to open its Component view.
2. In the Host name field, type in the host name or the IP address of the host server, `localhost` for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

**Job execution**

Press **F6** to run the Job.

Details of all of the databases in the Palo server are retrieved and listed in the console of the **Run** view.

<table>
<thead>
<tr>
<th></th>
<th>Database</th>

</tbody>
</table>

For further information about the output schema, see **Discovering the read-only output schema of tPaloDatabaseList** on page 2795.
tPaloDimension

Manages Palo dimensions, even elements inside a database.

The tPaloDimension creates, drops or recreates dimensions with or without dimension elements inside a Palo database.

tPaloDimension Standard properties

These properties are used to configure tPaloDimension running in the Standard Job framework.
The Standard tPaloDimension component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the Palo user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database in which the dimensions are managed.</td>
</tr>
<tr>
<td>Dimension</td>
<td>Type in the name of the dimension on which the given operation should take place.</td>
</tr>
<tr>
<td>Action on dimension</td>
<td>Select the operation you want to perform on the dimension of interest:</td>

</tr>
<tr>
<td></td>
<td>- Create dimension: the dimension does not exist and will be created.</td>
</tr>
<tr>
<td></td>
<td>- Create dimension if not exists: this dimension is created only when it does not exist.</td>
</tr>
<tr>
<td></td>
<td>- Delete dimension if exists and create: this dimension is deleted if exist and then a new one will be created.</td>
</tr>
<tr>
<td></td>
<td>- Delete dimension: this dimension is removed from the database.</td>
</tr>
</tbody>
</table>
### Create dimension elements

Select this check box to activate the dimension management fields and create dimension elements along with the creation of this dimension.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

- **DIMENSIONNAME**: the name of the dimension. This is an After variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

### Usage

| Usage rule | This component can be used in standalone or as end component of a process. |

**Note:**

The below fields are available only when the **Create dimension elements** check box is selected.

<table>

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
Creating a dimension with elements

The Job in this scenario creates a date dimension with simple element hierarchy composed of three levels: Year, Month, Date.

To replicate this scenario, proceed as follows:

Setting up the Job

Procedure

1. Drop tPaloConnection, tRowGenerator, tMap, tPaloDimension from the component Palette onto the design workspace.
2. Right-click tPaloConnection to open the contextual menu and select Trigger > On Subjob Ok to link it to tRowGenerator.
3. Right-click tRowGenerator to open the contextual menu and select Row > Main to link it to tMap.

Note:

RowGenerator is used to generate rows at random in order to simplify this process. In the real case, you can use one of the other input components to load your actual data.

4. Right-click tMap to open the contextual menu and select Row > New output to link to tPaloDimension, then name it as out1 in the dialog box that pops up.

Setting up the DB connection

Procedure

1. Double-click the tPaloConnection component to open its Component view.
2. In the *Host name* field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the *Server Port* field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the *Username* field and the *Password* field, type in the authentication information. In this example, both of them are *admin*.

**Configuring the input component**

**Procedure**

1. Double-click **tRowGenerator** to open its editor.

2. On the upper part of the editor, click the plus button to add one column and rename it as *random_date* in the *Column* column.

3. In the newly added row, select *Date* in the *Type* column and *getRandomDate* in the *Functions* column.

4. In the *Function parameters* view on the lower part of this editor, type in the new minimum date and maximum date values in the *Value* column. In this example, the minimum is *2010-01-01*, the maximum is *2010-12-31*.

5. Click **OK** to validate your modifications and close the editor.

6. On the dialog box that pops up, click **OK** to propagate your changes.

**Configuration in the tMap editor**

**Procedure**

1. Double-click **tMap** to open its editor.
2. On the Schema editor view on the lower part of the tMap editor, under the out1 table, click the plus button to add three rows.

3. In the Column column of the out1 table, type in the new names for the three newly added rows. They are Year, Month, and Date. These rows are then added automatically into the out1 table on the upper part of the tMap editor.

4. In the out1 table on the upper part of the tMap editor, click the Expression column in the Year row to locate the cursor.

5. Press Ctrl+space to open the drop-down variable list.

6. Double-click TalendDate.formatDate to select it from the list. The expression to get the date displays in the Year row under the Expression column. The expression is TalendDate.formatDate("yyyy-MM-dd HH:mm:ss", myDate).

7. Replace the default expression with TalendDate.formatDate("yyyy", row1.random_date).

8. Do the same for the Month row and the Date row to add this default expression and to replace it with TalendDate.formatDate("MM", row1.random_date) for the Month row and with TalendDate.formatDate("dd-MM-yyyy", row1.random_date) for the Date row.

9. Click OK to validate this modification and accept the propagation by clicking OK in the dialog box that pops up.

**Configuring the tPaloDimension component**

**Procedure**

1. On the workspace, double-click tPaloDimension to open its Component view.
2. Select the **Use an existing connection** check box. Then tPaloConnection_1 displays automatically in the **Connection configuration** field.

3. In the **Database** field, type in the database in which the new dimension is created, *talendDatabase* for this scenario.

4. In the **Dimension** field, type in the name you want to use for the dimension to be created, for example, *Date*.

5. In the **Action on dimension** field, select the action to be performed. In this scenario, select **Create dimension if not exist**.

6. Select the **Create dimension elements** check box.

7. In the **Consolidation Type** area, select the **Normal** check box.

8. Under the element hierarchy table in the **Consolidation Type** area, click the plus button to add three rows into the table.

9. In the **Input column** column of the element hierarchy table, select *Year* from the drop-down list for the first row, *Month* for the second and *Date* for the third. This determinates levels of elements from different columns of the input schema.

**Job execution**

Press **F6** to run the Job.

A new dimension is then created in your Palo database *talendDatabase*. 
tPaloDimensionList

Retrieves a list of dimension details from the given Palo database. tPaloDimensionList lists dimension names, dimension types, number of dimension elements, maximum dimension indent, maximum dimension depth, maximum dimension level, dimension id from a given Palo server.

**Discovering the read-only output schema of tPaloDimensionList**

The below table presents information related to the read-only output schema of the tPaloDimension List component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>

<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
## Global Variables

**DIMENSIONNAME**: the name of the dimension. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://help.talend.com).

## Usage

**Usage rule**

This component can be used in standalone or as start component of a process.

**Connections**

Outgoing links (from this component to another):
- **Row**: Main; Iterate.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Iterate
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see [Talend Studio User Guide](https://help.talend.com).

**Limitation**

The output schema is fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

## Retrieving detailed dimension information from a given database

The Job in this scenario retrieves details of all of the dimensions from a given database.
To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop tPaloDimensionList and tLogRow from the component Palette onto the design workspace.
2. Right-click tPaloDimensionList to open the contextual menu.
3. From this menu, select Row > Main to link the two components.

**Configuring the tPaloDimensionList component**

**Procedure**

1. Double-click the tPaloDimensionList component to open its Component view.
2. In the Host name field, type in the host name or the IP address of the host server, localhost for this example.
3. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.
4. In the Username field and the Password field, type in the authentication information. In this example, both of them are admin.
5. In the Database field, type in the database name where the dimensions of interest reside, Biker in this example.

**Job execution**

Press F6 to run the Job.

Details of all the dimensions in the Biker database are retrieved and listed in the console of the Run view.
For further information about the output schema, see Discovering the read-only output schema of tPaloDimensionList on page 2807.
tPaloInputMulti

Retrieves the stored or calculated values in combination with the element records out of a cube. The tPaloInputMulti retrieves data (elements as well as values) from a Palo cube.

**tPaloInputMulti Standard properties**

These properties are used to configure tPaloInputMulti running in the Standard Job framework. The Standard tPaloInputMulti component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database where the elements of interest reside.</td>
</tr>
<tr>
<td>Cube</td>
<td>Type in the name of the cube where the dimension elements to be retrieved are stored.</td>
</tr>
<tr>
<td>Cube type</td>
<td>Select the cube type from the drop-down list for the cube of concern. This type may be:</td>
</tr>
<tr>
<td></td>
<td>- Normal</td>
</tr>
<tr>
<td></td>
<td>- Attribut</td>
</tr>
<tr>
<td></td>
<td>- System</td>
</tr>
<tr>
<td></td>
<td>- User Info</td>
</tr>
<tr>
<td>Commit size</td>
<td>Type in the row count of each batch to be retrieved.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
</tbody>
</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Built-in

The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

### Repository

The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

### Cube Query

Complete this table with the query you want to use to retrieve data. The columns to be filled are:

- **Column**: the schema columns are added automatically to this column once defined in the schema editor. The schema columns are used to stored the retrieved dimension elements.
- **Dimensions**: type in each of the dimension names of the cube from which you want to retrieve dimension elements.

**Warning:**

_The dimension order listed in this column must be consistent with the order given in the cube that stores these dimensions._

- **Elements**: type in the dimension elements from which data is retrieved. If several elements are needed from one single dimension, separate them with a comma.

### Advanced settings

- **tStat Catcher Statistics**: Select this check box to collect log data at the component level.

### Global Variables

- **Global Variables**

  **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an output component.</th>
</tr>
</thead>
</table>

### Connections

**Outgoing links (from this component to another):**
- **Row:** Main
- **Trigger:** Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

**Incoming links (from one component to this one):**
- **Row:** Iterate
- **Trigger:** Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see Talend Studio User Guide.

### Limitation

According to the architecture of OLAP-Systems only one single value (text or numeric) could be retrieved from the cube. The MEASURE column and the TEXT column are fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Retrieving dimension elements from a given cube

The Job in this scenario retrieves several dimension elements from a demo Palo cube Sales.

To replicate this scenario, proceed as follows:

### Setting up the Job

**Procedure**

1. Drop tPaloInputMulti and tLogRow from the component Palette onto the design workspace.
2. Right-click tPaloInputMulti to open its contextual menu.
3. In the menu, select Row > Main to connect tPaloInputMulti to tLogRow with a row link.

**Setting up the DB connection**

**Procedure**

1. Double-click the tPaloInputMulti component to open its Component view.

   ![tPaloInputMulti Component View]

   - In the **Host name** field, type in the host name or the IP address of the host server, localhost for this example.
   - In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.
   - In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are admin.

2. In the Host name field, type in the host name or the IP address of the host server, localhost for this example.

3. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the Username field and the Password field, type in the authentication information. In this example, both of them are admin.

**Configuring the Cube Query**

**Procedure**

1. In the Database field, type in the database name in which the cube to be used is stored.

2. In the Cube field, type in the cube name in which the dimensions of interests are stored. In this scenario, it is one of the demo cubes Sales.

3. In the Cube type field, select the Normal type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

4. Next to the Edit schema field, click the three-dot button to open the schema editor.
5. In the schema editor, click the plus button to add the rows of the schema to be edited. In this example, add rows corresponding to all of the dimensions stored in the Sales cube: Products, Regions, Months, Years, Datatypes, Measures. Type in them in the order given in this cube.

6. Click OK to validate this editing and accept the propagation of this change to the next component. Then these columns are added automatically into the Column column of the Cube query table in the Component view. If the order is not consistent with the one in the Sales cube, adapt it using the up and down arrows under the schema table.

7. In the Dimensions column of the Cube query table, type in each of the dimension names stored in the Sales cube regarding to each row in the Column column. In the Sales cube, the dimension names are: Products, Regions, Months, Years, Datatypes, Measures.

8. In the Elements columns of the Cube query table, type in the dimension elements you want to retrieve regarding to the dimensions they belong to. In this example, the elements to be retrieved are All Products, Germany and Austria (Belonging to the same dimension Regions, these two elements are entered in the same row and separated with a comma), Jan, 2009, Actual, Turnover.

**Job execution**

**Procedure**

1. Click tLogRow to open its Component view.

2. In the Mode area, select the Table (print values in cells of a table) check box to display the execution result in a table.
3. Press **F6** to run the Job.

**Results**

The dimension elements and the corresponding Measure values display in the **Run** console.

```

tPaloOutput

Takes the input stream and writes it to a given Palo cube.

The tPaloOutput writes one row of data (elements as well as values) into a Palo cube.

tPaloOutput Standard properties

These properties are used to configure tPaloOutput running in the Standard Job framework.

The Standard tPaloOutput component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Host Name | Enter the host name or the IP address of the host server. |
| Server Port | Type in the listening port number of the Palo server. |
| Username and Password | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database | Type in the name of the database where the cube of interest resides. |
| Cube | Type in the name of the cube in which the incoming data is written. |
| Commit size | Type in the row count of each batch to be written into the cube. |
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the... |
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

<table>

<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Built-in

The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.

### Repository

The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.

### Measure value

Select the column from the input stream which holds the Measure or Text values.

### Splash mode

Select the splash mode used to write data into a consolidated element. The mode may be:

- **Add**: it writes values to the underlying elements.
- **Default**: it uses the default splash mode.
- **Set**: it simply sets or replaces the current value and make the distribution based on the other values.
- **Disable**: it applies no splashing.

For further information about the Palo splash modes, see Palo’s user guide.

### Add values

Select this check box to add new values to the current values for a sum. Otherwise these new values will overwrite the current ones.

### Use eventprocessor

Select this check box to call the supervision server.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the</th>
</tr>
</thead>
</table>
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an input component.</th>
</tr>
</thead>
</table>

Connections

Outgoing links (from this component to another):

Row: Main

Trigger: Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):

Row: Main; Reject

For further information regarding connections, see Talend Studio User Guide.

Limitation

Numeric measures are only be accepted as Double or String type. When the string type is used, write the value to be processed between quotation marks.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Writing data into a given cube

The Job in this scenario writes new values in the Sales cube given as demo in the Demo database installed with Palo.

To replicate this scenario, proceed as follows:
**Setting up the Job**

**Procedure**
1. Drop `tFixedFlowInput` and `tPaloOutputMulti` from the component Palette onto the design workspace.
2. Right-click `tFixedFlowInput` to open its contextual menu.
3. In this menu, select **Row > Main** to connect this component to `tPaloOutputMulti`.

**Configuring the input component**

**Procedure**
1. Double-click the `tFixedFlowInput` component to open its Component view.

   ![Component view](image)

   - **Basic settings**
   - **Advanced settings**
   - **Dynamic settings**
   - **View**
   - **Documentation**

   - Schema: **Built-In**
   - Number of rows: **1**

   - **Mode**
     - Use Single Table

   - **Values**
     - **Column**
       - Products: "Desktop L"  
       - Regions: "germany"  
       - Months: "Jan"  
       - Years: "2009"  
       - Datatypes: "Actual"  
       - Measures: "Turnover"  
       - Value: 1234.56

   - Use Inline Table
   - Use Inline Content (delimited file)

2. Click the three-dot button to open the schema editor.
3. In the schema editor, click the plus button to add 7 rows and rename them respectively as *Products*, *Regions*, *Months*, *Years*, *Datatypes*, *Measures* and *Values*. The order of these rows must be consistent with that of the corresponding dimensions in the *Sales* cube and the type of the *Value* column where the measure value resides is set to double/Double.

4. Click **OK** to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the *Value* table under the **Use single table** check box, in the **Mode** area.

5. In the *Value* table, type in values for each row in the *Value* column. In this example, these values are: *Desktop L, Germany, Jan, 2009, Actual, Turnover, 1234.56*.

### Configuring the output component

**Procedure**

1. Double-click **tPaloOutputMulti** to open its *Component* view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.

4. In the **Database** field, type in the database name in which you want to create the cube, `Demo` in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, `Sales`.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select `Value`.

**Job execution**

Press **F6** to run the Job.

The inflow data has been written into the `Sales` cube.

---

**Rejecting inflow data when the elements to be written do not exist in a given cube**

The Job in this scenario tries to write data into the `Sales` cube but as the elements of interest do not exist in this cube, the inflow data is rejected.

---

To replicate this scenario, proceed as follows:
### Setting up the Job

**Procedure**

1. Drop tFixedFlowInput, tPaloCheckElements, tPaloOutputMulti and tLogRow from the component Palette onto the design workspace.
2. Right-click tFixedFlowInput to open its contextual menu.
3. In this menu, select Row > Main to connect this component to tPaloCheckElements.
4. Do the same to connect tPaloOutputMulti using row link.
5. Right-click tPaloCheckElements to open its contextual menu.
6. In this menu, select Row > Reject to connect this component to tLogRow.

### Configuring the input component

**Procedure**

1. Double-click the tFixedFlowInput component to open its Component view.
2. Click the three-dot button to open the schema editor.

2. Click the three-dot button to open the schema editor.
3. In the schema editor, click the plus button to add 7 rows and rename them respectively as `Products`, `Regions`, `Months`, `Years`, `Datatypes`, `Measures` and `Values`. The order of these rows must be consistent with that of the corresponding dimensions in the `Sales` cube and the type of the `Value` column where the measure value resides is set to double/Double.

4. Click **OK** to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the **Value** table under the **Use single table** check box, in the **Mode** area.

5. In the **Value** table, type in values for each row in the **Value** column. In this example, these values are: **Smart Products, Germany, Jan, 2009, Actual, Turnover, 1234.56**. The **Smart Products** element does not exist in the **Sales** cube.

**Configuring the tPaloCheckElements component**

**Procedure**

1. Double-click **tPaloCheckElements** to open its **Component** view.
2. In the **Host name** field, type in *localhost*.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.

6. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.

7. In the **On Element error** field, select **Reject row** from the drop-down list.

8. In the element table at the bottom of the **Basic settings** view, click the **Element type** column in the **Value** row and select **Measure** from the drop down list.

**Configuring the output component**

**Procedure**

1. Double-click **tPaloOutputMulti** to open its **Component** view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

4. In the **Database** field, type in the database name in which you want to create the cube, *Demo* in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, *Sales*.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select *Value*.

**Job execution**

Press **F6** to run the Job.

The data to be written is rejected and displayed in the console of the **Run** view. You can read that the error message is *Smart Products*.

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can be used in standalone for rule creation, deletion or update. |

Connections

| Connections | Outgoing links (from this component to another): Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. Incoming links (from one component to this one): Row: Iterate Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. For further information regarding connections, see Talend Studio User Guide. |

Limitation

| Limitation | Update or deletion of a rule is available only when this rule has been created with external ID. Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Creating a rule in a given cube

The Job in this scenario creates a rule applied on dimensions of a given cube.
To replicate this scenario, proceed as follows:

**Setting up the DB connection**

**Procedure**

1. Drop `tPaloRule` from the component `Palette` onto the design workspace.
2. Double-click the `tPaloRule` component to open its `Component` view.

3. In the **Host name** field, type in the host name or the IP address of the host server, `localhost` for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.
5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.
6. In the **Database** field, type in the database name in which the dimensions applying the created rules reside, `Biker` in this example.
7. In the **Cube** field, type in the name of the cube which the dimensions applying the created rules belong to, for example, `Orders`. 
Setting the Cube rules

Procedure

1. Under the Cube rules table, click the plus button to add a new row.
2. In the Cube rules table, type in ['2009'] = 123 in the Definition column, OrderRule1 in the External Id column and Palo Demo Rules in the Comment column.
3. In the Activated column, select the check box.
4. In the Action column, select Create from the drop-down list.

Job execution

Press F6 to run the Job.

The new rule has been created and the value of every 2009 element is 123.
tPaloRuleList

Lists all rules, formulas, comments, activation status, external IDs from a given cube.

The tPaloRuleList retrieves a list of rule details from the given Palo database.

Discovering the read-only output schema of tPaloRuleList

The following table presents information related to the read-only output schema of the tPaloRuleList component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>rule_identifier</td>
<td>long</td>
<td>The internal identifier/id for this rule.</td>
</tr>
<tr>
<td>rule_definition</td>
<td>string</td>
<td>The formula of this rule. For further information about this formula, see the Palo user guide.</td>
</tr>
<tr>
<td>rule_extern_id</td>
<td>string</td>
<td>The user-defined external id.</td>
</tr>
<tr>
<td>rule_comment</td>
<td>string</td>
<td>The user-edited comment on this rule.</td>
</tr>
<tr>
<td>rule_activated</td>
<td>boolean</td>
<td>Indicates if this rule had been activated or not.</td>
</tr>
</tbody>
</table>

**tPaloRuleList Standard properties**

These properties are used to configure tPaloRuleList running in the Standard Job framework.

The Standard tPaloRuleList component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

**Basic settings**

- **Use an existing connection**: Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
  
  Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

- **Host Name**: Enter the host name or the IP address of the host server.

- **Server Port**: Type in the listening port number of the Palo server.

- **Username and Password**: Enter the Palo user authentication data.
  
  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

- **Database**: The name of the database where the cube of interest resides.
### Cube
Type in the name of the cube in which you want to retrieve the rule information.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th><strong>Built-in</strong></th>
<th>The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong></td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Advanced settings
- **tStat Catcher Statistics**
  Select this check box to collect log data at the component level.

### Global Variables
**Global Variables**

- **NB_RULES**: the number of rules. This is an After variable and it returns an integer.
- **EXTERNAL_RULEID**: the external ID of the rule. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used in standalone or as start component of a process.</th>
</tr>
</thead>
</table>

#### Connections

<table>
<thead>
<tr>
<th>Outgoing links (from this component to another):</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row:</strong> Main; Iterate.</td>
</tr>
<tr>
<td><strong>Trigger:</strong> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Incoming links (from one component to this one):</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row:</strong> Iterate</td>
</tr>
<tr>
<td><strong>Trigger:</strong> Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.</td>
</tr>
</tbody>
</table>

For further information regarding connections, see [Talend Studio User Guide](https://help.talend.com).

#### Limitation

- The output schema is fixed and read-only.
- Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Retrieving detailed rule information from a given cube

The Job in this scenario retrieves rule details applied on the dimensions of a given cube.

To replicate this scenario, proceed as follows:

### Setting up the Job

#### Procedure

1. Drop **tPaloRuleList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloRuleList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

### Configuring the **tPaloRuleList** component

#### Procedure

1. Double-click the **tPaloRuleList** component to open its **Component** view.
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** and **Password** fields, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name where the dimensions applying the rules of interest reside, *Biker* in this example.

6. In the **Cube** field, type in the name of the cube which the rules of interest belong to.

**Job execution**

Press **F6** to run the Job.

Details of all of the rules in the *Orders* cube are retrieved and listed in the console of the **Run** view.

```plaintext
[statistics] connecting to socket on port 3743
[statistics] connected
-------------------------------------------------------------------------
| rule_identifier | rule_definition | rule_extern_id | rule_comment | rule_activated |
-------------------------------------------------------------------------
| 1 | ['2009'] = 123 | OrderRule1 | Palo Demo Rules | true |
-------------------------------------------------------------------------
[statistics] disconnected
Job tpalo ended at 16:35 12/11/2010. [exit code=0]
```

For further information about the output schema, see *Discovering the read-only output schema of tPaloRuleList* on page 2835.
tParAccelBulkExec

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelBulkExec performs an Insert action on the data.

tParAccelBulkExec Standard properties

These properties are used to configure tParAccelBulkExec running in the Standard Job framework.

The Standard tParAccelBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
</tbody>
</table>

Built-in: No property data stored centrally.

Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **Host** | Database server IP address. |
| **Port** | Listening port number of the DB server. |
| **Database** | Database name. |
| **Schema** | Exact name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | On the table defined, you can perform one of the following operations:  
  - **None**: No operation is carried out.  
  - **Drop and create table**: The table is removed and created again.  
  - **Create table**: The table does not exist and gets created.  
  - **Create table if not exists**: The table is created if it does not exist.  
  - **Drop table if exists and create**: The table is removed if already exists and created again.  
  - **Clear table**: The table content is deleted. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
  - **Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.  
  - **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).  
  - Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
    - **View schema**: choose this option to view the schema only.  
    - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

</table>

### Usage

#### Usage rule

This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row > Reject link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2500.

#### Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

#### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Related scenarios

For related scenarios, see:

- Inserting transformed data in MySQL database on page 2508 of tMysqlOutputBulk.
- Inserting data in bulk in MySQL database on page 2515 of tMysqlOutputBulkExec.
- Truncating and inserting file data into an Oracle database on page 2716 of tOracleBulkExec.
tParAccelClose

Closes a transaction.
The tParAccelClose closes the transaction committed in the connected DB.

**tParAccelClose Standard properties**

These properties are used to configure tParAccelClose running in the Standard Job framework.
The Standard tParAccelClose component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection. For more information about
dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tParAccelConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with ParAccel components, especially with **tParAccelConnection** and **tParAccelCommit**. |

**Dynamic settings**

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic
settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tParAccelCommit

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus provides gain in performance.

The tParAccelCommit validates the data processed through the job into the connected DB.

tParAccelCommit Standard properties

These properties are used to configure tParAccelCommit running in the Standard Job framework.

The Standard tParAccelCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tParAccelConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tParAccelCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tParAccel* components, especially with the tParAccelConnection and tParAccelRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tParAccelCommit related scenario, see Inserting data in mother/daughter tables on page 2452
tParAccelConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.
The tParAccelConnection opens a connection to the database for a current transaction.

tParAccelConnection Standard properties

These properties are used to configure tParAccelConnection running in the Standard Job framework.
The Standard tParAccelConnection component belongs to the Databases and the ELT families.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection. For more information about
dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the</td>
</tr>
<tr>
<td></td>
<td>properties are stored. The fields that follow are</td>
</tr>
<tr>
<td></td>
<td>completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>

</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the</td>
</tr>
</tbody>
</table>
**tParAccelConnection**

**Advanced settings**

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

**Usage**

| **Usage rule** | This component is more commonly used with other tParAccel* components, especially with the tParAccelCommit and tParAccelRollback components. |
| **Limitation** | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenario**

For **tParAccelConnection** related scenario, see **tMysqlConnection** on page 2451
tParAccelInput

Reads a database and extracts fields based on a query.

tParAccelInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tParAccelInput Standard properties**

These properties are used to configure tParAccelInput running in the Standard Job framework.
The Standard tParAccelInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.

For more information about setting up and storing database connection parameters, see Talend Studio User Guide.

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>

<td></td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
<td></td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
<td></td>
</tr>
</tbody>
</table>
Table name

Name of the table to be read.

Query type and Query

Enter your DB query paying particularly attention to sequence the fields properly in order to match the schema definition.

Guess Query

Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.

Guess schema

Click the Guess schema button to retrieve the table schema.

Advanced settings

Additional JDBC Parameters

Specify additional JDBC parameters for the database connection being created.

This property is not available when the Use an existing connection check box in the Basic settings view is selected.

Use cursor

When selected, helps to decide the row set to work with at a time and thus optimize performance.

Trim all the String/Char columns

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

Trim column

Remove leading and trailing whitespace from defined columns.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

NB_LINE: the number of rows processed. This is an After variable and it returns an integer.

QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component covers all possible SQL queries for ParAccel databases.
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The *Dynamic settings* table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenarios**

For related scenarios, see:
tParAccelOutput

Executes the action defined on the table and/or on the data of a table, according to the input flow form the previous component.

The tParAccelOutput writes, updates, modifies or deletes the data in a database.

tParAccelOutput Standard properties

These properties are used to configure tParAccelOutput running in the Standard Job framework.

The Standard tParAccelOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

| **Host** | Database server IP address. |
| **Port** | Listening port number of the DB server. |
| **Database** | Database name. |
| **Schema** | Exact name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | On the table defined, you can perform one of the following operations:
  - **None**: No operation is carried out.
  - **Drop and create table**: The table is removed and created again.
  - **Create table**: The table does not exist and gets created.
  - **Create table if not exists**: The table is created if it does not exist.
  - **Drop table if exists and create**: The table is removed if already exists and created again.
  - **Clear table**: The table content is deleted. |
| **Action on data** | On the data of the table defined, you can perform:
  - **Insert**: Add new entries to the table. If duplicates are found, job stops.
  - **Update**: Make changes to existing entries
  - **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
  - **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
  - **Delete**: Remove entries corresponding to the input flow. |
### Warning:

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do this by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete** operation.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

### Built-In

You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.
### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional JDBC parameters for the database connection being created. This property is not available when the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong> view is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Commit every</strong></td>
<td>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</td>
</tr>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td><strong>Name:</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column</td>
</tr>
<tr>
<td><strong>SQL expression:</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position:</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column:</strong></td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This check box is available only when you have selected the <strong>Insert</strong>, <strong>Update</strong>, or <strong>Delete</strong> option in the <strong>Action on data</strong> option.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the <strong>Use batch mode</strong> check box is selected.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

| **Global Variables** | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.

NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.

NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

Usage

Usage rule

This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row > Rejects link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2500.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio.
Related scenarios

For a related scenario, see:

• Inserting a column and altering data using tMysqlOutput on page 2492.
tParAccelOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelOutputBulk writes a file with columns based on the defined delimiter and the ParAccel standards.

### tParAccelOutputBulk Standard properties

These properties are used to configure tParAccelOutputBulk running in the Standard Job framework.

The Standard tParAccelOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to Built-in for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

</tbody>
</table>
Usage

Usage rule | This component is to be used along with `tParAccelBulkExec` component. Used together they offer gains in performance while feeding a ParAccel database.
--- | ---
Component family | Databases/ParAccel

Related scenarios

For use cases in relation with `tParAccelOutputBulk`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tParAccelOutputBulkExec

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in tParAccelOutputBulkExec.

The tParAccelOutputBulkExec performs an Insert action on the data.

**tParAccelOutputBulkExec Standard properties**

These properties are used to configure tParAccelOutputBulkExec running in the Standard Job framework.

The Standard tParAccelOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

* **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
| **Copy mode** | Click *Edit schema* to make changes to the schema. If the current schema is of the *Repository* type, three options are available:  
* **View schema**: choose this option to view the schema only.  
* **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.  
* **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select *No* upon completion and choose this schema metadata again in the *Repository Content* window.  
Select the copy mode you want to use from either:  
* **Basic**: Standard mode, without optimisation.  
* **Parallel**: Allows you to use several internal ParAccel APIs in order to optimise loading speed. |
| **Filename** | Name of the file to be generated and loaded. |
### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row &gt; Reject link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2500.</td>
<td></td>
</tr>
<tr>
<td>Limitation</td>
<td>The database server must be installed on the same machine where the Studio is installed or where the Job using</td>
</tr>
</tbody>
</table>
tParAccelOutputBulkExec is deployed, so that the component functions properly.

Related scenarios

For related scenarios, see:

- Inserting transformed data in MySQL database on page 2508 of tMysqlOutputBulk.
- Inserting data in bulk in MySQL database on page 2515 of tMysqlOutputBulkExec.
- Truncating and inserting file data into an Oracle database on page 2716 of tOracleBulkExec.
tParAccelRollback

Avoids to commit part of a transaction involuntarily.
The tParAccelRollback cancels the transaction commit in the connected DB.

**tParAccelRollback Standard properties**

These properties are used to configure tParAccelRollback running in the Standard Job framework.
The Standard tParAccelRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tParAccelConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tParAccel* components, especially with the tParAccelConnection and tParAccelCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection |
Related scenario

For `tParAccelRollback` related scenario, see `tMysqlRollback` on page 2517.
tParAccelRow

Acts on the actual DB structure or on the data (although without handling data), depending on
the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL
statements.

The tParAccelRow is the specific component for this database query. It executes the SQL query stated
onto the specified database. The row suffix means the component implements a flow in the job
design although it doesn’t provide output.

tParAccelRow Standard properties

These properties are used to configure tParAccelRow running in the Standard Job framework.

The Standard tParAccelRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related
to database settings vary depending on your database type selection. For more information about
dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **Host** | Database server IP address |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database |
| **Schema** | Exact name of the schema. |
| **Username and Password** | DB user authentication data. 
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window.

**Table Name**

Name of the table to be read.

**Query type**

Either **Built-in** or **Repository**.

- **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.
- **Repository**: Select the relevant query stored in the Repository. The **Query** field gets accordingly filled in.

**Guess Query**

Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.
Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

Advanced settings

Additional JDBC Parameters

Specify additional JDBC parameters for the database connection being created.

This property is not available when the Use an existing connection check box in the Basic settings view is selected.

Propagate QUERY’s recordset

Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.

Note:
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.

Use PreparedStatement

Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by ‘?’ in the SQL instruction of the Query field in the Basic Settings tab.

Parameter Index: Enter the parameter position in the SQL instruction.

Parameter Type: Enter the parameter type.

Parameter Value: Enter the parameter value.

Note:
This option is very useful if you need to execute the same query several times. Performance levels are increased.

Commit every

Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

QUERY: the query statement being processed. This is a Flow variable and it returns a string.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For a related scenario, see:

- Combining two flows for selective output on page 2529
- Procedure on page 635.
- Removing and regenerating a MySQL table index on page 2523.
tParAccelSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

The tParAccelSCD reflects and tracks changes in a dedicated ParAccel SCD table.

**tParAccelSCD Standard properties**

These properties are used to configure tParAccelSCD running in the Standard Job framework.

The Standard tParAccelSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</table>
| **Prerequisites** | The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.  
- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under **MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native**. For example, the library for Windows is **\lib\native\MapRClient.dll** in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr). Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.  
- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of |

2879
the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | Knowledge of Pig scripts is required. |

**Related scenario**

For a tPigAggregate related scenario, Aggregating values and sorting data on page 138 of tAggregateRow.
tPigCode

Extends the functionalities of a Talend Job through using Pig scripts.

The tPigCode enters personalized Pig code to integrate it in Talend program. You can execute this code only once.

**tPigCode Standard properties**

These properties are used to configure tPigCode running in the Standard Job framework.

The Standard tPigCode component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>
| **Scripts** | Type in Pig scripts you want to execute depending on the task you need to perform. For further information about Pig functions syntax, see Apache’s documentation about Pig UDF: http://pig.apache.org  
Pig components output tuples and automatically set up an alias for each tuple. When you use a tuple in your Pig script, you have to enter the right alias.  
The alias syntax is Component_ID_rowID_Result, for example, tPigCode_1_row2_Result. |
## Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable escape</td>
<td>Select this check box so that you can simply write plain Pig code in the <strong>Scripts</strong> field without need to bear in mind the escape characters, otherwise required for proper Java code generation.</td>
</tr>
</tbody>
</table>

## Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |
|-------------------|-----------------------------------------------------------------------------------------------------------------|

## Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component.  
A **tPigCode** component can execute only one Pig Latin statement, therefore, if you need to execute multiple statements, you have to use a corresponding number of **tPigCode** components to run them, one after another.  
If a particular .jar file is required to execute a statement, you need to register that library file via the **tPigLoad** component that starts the Pig process in question. |
|------------|---------------------------------------------------------------------------------------------------------------|
| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.  
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine.  
According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).  
Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`. |
Set the `-Djava.library.path` argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

| Limitation | Knowledge of Pig scripts is required. |

---

**Selecting a column of data from an input file and store it into a local file**

This scenario applies only to Talend products with Big Data.

This scenario describes a three-component Job that selects a column of data that matches filter condition defined in `tPigCode` and stores the result into a local file.

![Diagram of Job](image)

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette to the design workspace: `tPigCode`, `tPigLoad`, `tPigStoreResult`.
2. Right-click `tPigLoad` to connect it to `tPigCode` using a Row > Pig Combine connection.
3. Right-click `tPigCode` to connect it to `tPigStoreResult` using a Row > Pig Combine connection.

**Loading the data**

**Procedure**

1. Double-click `tPigLoad` to open its Basic settings view.
2. Click the three-dot button next to **Edit schema** to add columns for **tPigLoad**.

3. Click the plus button to add **Name**, **Country** and **Age** and click **OK** to save the setting.

4. Select **Local** from the **Mode** area.

5. Fill in the **Input filename** field with the full path to the input file.
   In this scenario, the input file is **CustomerList** which contains rows of names, country names and age.

6. Select **PigStorage** from the **Load function** list.

7. Leave rest of the settings as they are.

**Configuring the tPigCode component**

**Procedure**

1. Double-click **tPigCode** component to open its **Basic settings** view.
2. Click **Sync columns** to retrieve the schema structure from the preceding component.
3. Fill in the **Script Code** field with following expression:

   ```
   tPigCode_1_row2_RESULT = foreach tPigLoad_1_row1_RESULT generate $0 as name;
   ```

   This filter expression selects column *Name* from *CustomerList*.

**Saving the result data to a local file**

**Procedure**

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

   2. Click **Sync columns** to retrieve the schema structure from the preceding component.
   3. Fill in the **Result file** field with the full path to the result file.
      In this scenario, the result is saved in *Result* file.
   4. Select **Remove result directory if exists**.
   5. Select **PigStorage** from the **Store function** list.
   6. Leave rest of the settings as they are.

**Executing the Job**

Save your Job and press **F6** to run it.
<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mike</td>
</tr>
<tr>
<td>Silvia</td>
</tr>
<tr>
<td>Romeo</td>
</tr>
<tr>
<td>Ahmad</td>

<tr>
<td>Didi</td>
</tr>
<tr>
<td>Juan</td>
</tr>
<tr>
<td>Bob</td>
</tr>
<tr>
<td>Mario</td>
</tr>
<tr>
<td>Ricky</td>
</tr>
</tbody>
</table>

The `Result` file is generated containing the selected column of data.
tPigCoGroup

Performs the Pig COGROUP operation to group and aggregate data incoming from multiple Pig flows. The tPigCoGroup groups data from as many inputs as needed incoming from its preceding Pig components and aggregates the grouped data using some given function before sending the data to the next Pig component.

**tPigCoGroup Standard properties**

These properties are used to configure tPigCoGroup running in the Standard Job framework. The Standard tPigCoGroup component belongs to the Big Data and the Processing families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the `Repository` type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to `Built-in` for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide.* |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide.* |
| **Group by** | Click the `[+]` button to add one or more columns of the input flows to this **Group by** table so as to set these columns as group condition. |
| **Output mapping** | This table is automatically filled with the output schema you have defined using the **Schema** field. Then complete this table to configure how the grouped data is aggregated in the output flow:
- **Function**: select the function you need to use to aggregate a given column. |
**Source schema:** select the input flow from which you aggregate the data.

**Expression:** select the column to be aggregated and if needed, edit expressions

### Advanced settings

**Group optimization**

Select the Pig algorithm depending on the situation of the input data and the loader you are using to optimize the COGROUP operation.

For further information, see Apache's documentation about Pig.

**Use partitioner**

Select this check box to call a Hadoop partitioner in order to partition records and return the reduce task or tasks that each record should go to.

Note that this partitioner class must be registered in the Register jar table provided by the `tPigLoad` component that starts the current Pig process.

**Increase parallelism**

Select this check box to set the number of reduce tasks for the MapReduce Jobs.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

### Usage

**Usage rule**

This component is commonly used as intermediate step together with input component and output component.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with **Talend Studio**. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine.
- According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS...
version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Limitation

Knowledge of Pig scripts is required.

**Aggregating data from two relations using COGROUP**

This scenario applies only to Talend products with Big Data.

In this scenario, a four-component Job is designed to aggregate two relations on top of a given Hadoop cluster.

The two relations used in this scenario consist of the following sample data:

1. Alice,turtle,17
   Alice,goldfish,17
   Alice,cat,17
   Bob,dog,18
   Bob,cat,18
   John,dog,19
   Mary,goldfish,16
   Bill,dog,20
This relation is composed of three columns that read owner, pet and age (of the owners).

2. Cindy,Alice  
   Mark,Alice  
   Paul, Bob  
   Paul, Jane  
   John, Mary  
   William, Bill

This relation provides a list of students' names alongside their friends, of which some are pet owners displayed in the first relation. Therefore, the schema of this relation contains two columns: student and friend.

Before replicating this scenario, you need to write the sample data into the HDFS system of the Hadoop cluster to be used. To do this, you can use tHDFSOutput. For further information about this component, see tHDFSOutput on page 1531.

The data used in this scenario is inspired by the examples that Pig's documentation uses to explain the GROUP and the GOGROUP operators. For related information, please see Apache's documentation for Pig.

**Linking the components**

**Procedure**

1. In the Integration perspective of the Studio, create an empty Job from the Job Designs node in the Repository tree view.  
   For further information about how to create a Job, see Talend Studio User Guide.

2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are two tPigLoad components, a tPigCoGroup component and a tPigStoreResult component. One of the two tPigLoad components is used as the main loading component to connect to the Hadoop cluster to be used.

3. Connect the main tPigLoad component to tPigCoGroup using the Row > Main link.

4. Do the same to connect the second tPigLoad component to tPigCoGroup. The Lookup label appears over this link.

5. Repeat the operation to connect tPigCoGroup to tPigStoreResult.

**Reading data into the Pig flow**

**Reading the owner-pet sample data**

**Procedure**

1. Double-click the main tPigLoad component to open its Component view.
2. Click the [...] button next to **Edit schema** to open the schema editor and click the [+\(\)] button three times to add three rows.

3. In the **Column** column, rename the new rows to *owner*, *pet* and *age*, respectively, and in the **Type** column of the *age* row, select **Integer**.

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the **Mode** area, select **Map/Reduce** to use the remote Hadoop cluster to be used.

6. In the **Distribution** and the **Version** lists, select the Hadoop distribution you are using. In this example, **HortonWorks Data Platform V2.1.0 (Baikal)** is selected.

7. In the **Load function** list, select **PigStorage**. Then, the corresponding parameters to be set appear.

8. In the **NameNode URI** and the **Resource manager** fields, enter the locations of those services, respectively. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

9. Select the **Set resourcemanager scheduler address** check box and enter the URI of this service in the field that is displayed. This allows you to use the Scheduler service defined in the Hadoop cluster to be used. If this service is not defined in your cluster, you can ignore this step.

10. In the **User name** field, enter the name of the user having the appropriate right to write data in the cluster. In this example, it is `hdfs`.

11. In the **Input file URI** field, enter the path pointing to the relation you need to read data from. As explained previously, the relation to be read here is the one containing the owner and pet sample data.
12. In the **Field separator** field, enter the separator of the data to be read. In this example, it is semicolon (;).

**Loading the student-friend sample data**

**Procedure**

1. Double-click the second **tPigLoad** component to open its **Component** view.

   ![Component view of tPigLoad](image)

   - **Field separator**: Semicolon (;
   - **Distribution**: HortonWorks
   - **Version**: Hortonworks Data Platform V2.1.0(Baikal)
   - **Load function**: PigStorage

2. Click the [...] button next to **Edit schema** to open the schema editor.

3. Click the [+ ] button twice to add two rows and in the **Column** column, rename them to **student** and **friend**, respectively.

   ![Schema editor](image)

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the **Mode** area, select **Map/Reduce**.
   
   This component reuses the Hadoop connection you have configured in that main **tPigLoad** component. Therefore, the **Distribution** and the **Version** fields have been automatically filled with the values from that main loading component.

6. In the **Load function** field, select the **PigStorage** function to read the source data.
7. In the **Input file URI** field, enter the directory where the source data is stored. As explained previously, this data is from the second relation containing the student and friend sample data.

### Aggregating the relations

#### Procedure

1. Double-click **tPigCoGroup** to open its **Component** view.

![Component view](image.png)

2. Click the ![button](image.png) button next to **Edit schema** to open the schema editor.

3. Click the ![button](image.png) button five times to add five rows and in the **Column** column, rename them to **owner_friend**, **age**, **pet_number**, **pet** and **student**, respectively.

4. In the **Type** column of the **age** row, select **Integer**.

5. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

6. In the **Group by** table, click the ![button](image.png) button once to add one row.

7. Then you need to set the grouping condition in this **Group by** table to aggregate the two input relations. In each column representing the input relation, click the newly added row and select the column you need to use to compose the grouping condition. In this scenario, the **owner** column from the owner-pet relation and the **friend** column from the student-friend relation are selected because they have common records. Based on these columns, the two relations are aggregated into bags.

   The bags regarding the record **Alice** might read as follow:
   
   ```
   Alice, {(Alice,turtle,17), (Alice,goldfish,17), (Alice,cat,17)}, {(Cindy,Alice), (Mark,Alice)}
   ```

8. In the **Output mapping** table, the output schema you defined previously has been automatically fed into the **Column** column. You need to complete this table to define how the grouped bags are aggregated into the schema of the output relation. The following list provides more details about how this aggregation is configured for this scenario:
<table>
<thead>
<tr>
<th>Column</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>owner_friend</td>
<td>Receive the literal records incoming from the columns that are used as the grouping condition. For this reason, select the <strong>EMPTY</strong> function from the Function drop-down list so that the incoming records stay as is. Then select row1 from the Source schema list and owner from the Expression list to read the records from the corresponding input column; you can as well select row2 and friend, the records to be received are the same because the owner column and the friend column are joined when they are used as grouping condition. Note that the label row1 is the ID of the input link and thus may be different in your scenario.</td>
</tr>
<tr>
<td>age</td>
<td>Receive the age data. As shown in the example bags in the previous step, the age of an owner repetitively appears in one of the bags after the grouping. You can select the <strong>AVG</strong> function from the Function list to make the average of the repetitive values such that this age appears only once in the final result. Then select row1 from the Source schema list and age from the Expression list.</td>
</tr>
<tr>
<td>pet_number</td>
<td>Receive how many pets an owner has. Select the <strong>COUNT</strong> function from the Function list to perform this calculation. Then select row1 from the Source schema list and pet from the Expression list.</td>
</tr>
<tr>
<td>pet and student</td>
<td>Receive the grouped records from the input pet and student columns, respectively. Select <strong>EMPTY</strong> for both of them and from the Source schema list of each, select the corresponding input schema and from the Expression list, the corresponding column.</td>
</tr>
</tbody>
</table>

**Writing the aggregated data**

**Procedure**

1. Double-click **tPigStoreResult** to open its Component view.
2. If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

3. In the **Result folder URI** field, enter the path in HDFS pointing to the location you want to write the result in.

4. Select the **Remove result directory if exists** check box.

5. From the **Store function** list, select **PigStorage**.

6. In the **Field separator** field, enter the separator you want to use. In this scenario, enter a comma (,).

**Executing the Job**

Then you can press **F6** to run this Job.

Once done, check the result from the HDFS system you are using.

```
1  Bob,18.0,2,{{cat),(dog)}},{{Paul}}
2  Bill,20.0,1,{{dog}}},{{William}}
3  Jane,,0,{},{{Paul}}
4  John,19.0,1,{{dog}}},{}
5  Mary,16.0,1,{{goldfish}}},{{John}}
6  Alice,17.0,3,{{cat),(goldfish),(turtle)}},{{Mark),(Cindy}}
```

You can read, for example, that the pet owner Alice is 17 years old, has 3 pets, a cat, a goldfish and a turtle and two of her friends are Mark and Cindy.
tPigCross

Uses CROSS operator to compute the Cartesian product.
The tPigCross computes the cross data of two or more relations.

**tPigCross Standard properties**

These properties are used to configure tPigCross running in the Standard Job framework.
The Standard tPigCross component belongs to the Big Data and the Processing families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- View schema: choose this option to view the schema only.  
- Change to built-in property: choose this option to change the schema to Built-in for local changes.  
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| Built-in: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide. |
| Cross filename | Fill in the path of the file to be computed. |
| Field separator | Enter character, string or regular expression to separate fields for the transferred data. |

**Advanced settings**

<p>| Use partitioner | Select this check box to specify the Hadoop Partitioner that controls the partitioning of the keys of the intermediate map-outputs. For further information about the usage of Hadoop Partitioner, see: |</p>
<table>
<thead>
<tr>
<th>Increase parallelism</th>
<th>Select this check box to set the number of reduce tasks for the MapReduce Jobs</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component is commonly used as intermediate step together with input component and output component.

**Prerequisites**

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.

- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.
For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Knowledge of Pig scripts is required.</th>
</tr>
</thead>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tPigDistinct

Removes duplicate tuples in a relation.

**tPigDistinct Standard properties**

These properties are used to configure tPigDistinct running in the Standard Job framework.

The Standard tPigDistinct component belongs to the Big Data and the Processing families.

The component in this framework is available in all **Talend products with Big Data** and in **Talend Data Fabric**.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  

| Built-in: The schema will be created and stored locally for this component only. Related topic: see **Talend Studio User Guide**. |  
| Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see **Talend Studio User Guide**. |

**Advanced settings**

| Increase parallelism | Select this check box to set the number of reduce tasks for the **MapReduce** Jobs |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR MESSAGE**: the error message generated by the component when an error occurs. This is an After variable |
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<th>This component is commonly used as intermediate step together with input component and output component.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong></td>
<td>This component will not maintain the original order in the input file.</td>
</tr>
</tbody>
</table>

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Limitation

| Limitation | Knowledge of Pig scripts is required. |
Related scenario

For more information regarding the `tPigDistinct` component in use, see Filtering rows of data based on a condition and saving the result to a local file on page 2906 of `tPigFilterRow`. 
tPigFilterColumns

Selects data or filters out data from a relation based on defined filter conditions.
The tPigFilterColumns selects one or more columns from a relation based on defined condition.

**tPigFilterColumns Standard properties**

These properties are used to configure tPigFilterColumns running in the Standard Job framework. The Standard tPigFilterColumns component belongs to the Big Data and the Processing families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| Built-in: The schema will be created and stored locally for this component only. Related topic: see **Talend Studio User Guide**. |
| Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see **Talend Studio User Guide**. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |

Filtering rows of data based on a condition and saving the result to a local file

This scenario applies only to Talend products with Big Data.

This scenario describes a four-component Job that filters a list of customers to find out customers from a particular country, and saves the result list to a local file. Before the input data is filtered, duplicate entries are first removed from the list.

The input file contains three columns: Name, Country, and Age, and it has some duplicate entries, as shown below:

```
Mario;PuertoRico;49
Mike;USA;22
Ricky;PuertoRico;37
Silvia;Spain;20
Billy;Canada;21
Ricky;PuertoRico;37
Romeo;UK;19
Natasha;Russia;25
Juan;Cuba;23
Bob;Jamaica;55
Mario;PuertoRico;49
```

Dropping and linking components

Procedure

1. Drop the following components from the Palette to the design workspace: tPigLoad, tPigDistinct, tPigFilterRow, and tPigStoreResult.
2. Right-click tPigLoad, select Row > Pig Combine from the contextual menu, and click tPigDistinct to link these two components.
3. Repeat this operation to link tPigDistinct to tPigFilterRow, and tPigFilterRow to tPigStoreResult using Row > Pig Combine connections to form a Pig process.
Configuring the components

Loading the input data and removing duplicates

Procedure

1. Double-click tPigLoad to open its Basic settings view.

   ![](image)

2. Click the [...] button next to Edit schema to open the Schema dialog box.
3. Click the [+] button to add three columns according to the data structure of the input file: Name (string), Country (string) and Age (integer), and then click OK to save the setting and close the dialog box.

4. Click Local in the Mode area.

5. Fill in the Input file URI field with the full path to the input file.

6. Select PigStorage from the Load function list, and leave rest of the settings as they are.

7. Double-click tPigDistinct to open its Basic settings view, and click Sync columns to make sure that the input schema structure is correctly propagated from the preceding component. This component will remove any duplicates from the data flow.

Configuring the filter

Procedure

1. Double-click tPigFilterRow to open its Basic settings view.

2. Click Sync columns to make sure that the input schema structure is correctly propagated from the preceding component.

3. Select Use advanced filter and fill in the Filter field with filter expression:

   "Country matches 'PuertoRico'"

   This filter expression selects rows of data that contains "PuertoRico" in the Country column.
Configuring the file output

Procedure

1. Double-click **tPigStoreResult** to open its **Basic settings** view.

2. Click **Sync columns** to make sure that the input schema structure is correctly propagated from the preceding component.

3. Fill in the **Result file** field with the full path to the result file.

4. If the target file already exists, select the **Remove result directory if exists** check box.

5. Select **PigStorage** from the **Store function** list, and leave rest of the settings as they are.

Saving and executing the Job

Procedure

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click the **Run** button on the **Run** tab to run the Job.

The result file contains the information of customers from the specified country.

<table>
<thead>

**tPigJoin**

Performs inner joins and outer joins of two files based on join keys to create data that will be used by Pig.

The tPigJoin performs join of two files based on join keys.

**tPigJoin Standard properties**

These properties are used to configure tPigJoin running in the Standard Job framework.

The Standard tPigJoin component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  

**Note:**

To make this component work, two schemas must be set: the schema of the main flow and the schema of the lookup flow. In the output part of the main schema, the columns of the main input file must be manually concatenated with those of the lookup file. |

| Built-in: | The schema will be created and stored locally for this component only. Related topic: see **Talend Studio User Guide**. |
| Repository: | The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see **Talend Studio User Guide**. |

</thead>
</table>

### Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under \MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the...
Joining two files based on an exact match and saving the result to a local file

This scenario applies only to Talend products with Big Data.

This scenario describes a four-component Job that combines data of an input file and a reference file that matches a given join key, removes unwanted columns, and then saves the final result to a local file.

The main input file contains the information about people’s IDs, first names, last names, group IDs, and salaries, as shown below:

```
1;Woodrow;Johnson;3;1013.39
2;Millard;Monroe;2;8077.59
3;Calvin;Eisenhower;3;6866.88
4;Lyndon;Wilson;3;5726.28
5;Ronald;Garfield;2;4158.58
6;Rutherford;Buchanan;3;2897.00
7;Calvin;Coolidge;1;6650.66
8;Ulysses;Roosevelt;2;7854.78
9;Grover;Tyler;1;5226.88
10;Bill;Tyler;2;8964.66
```

The reference file contains only the information of group IDs and group names:

```
1;group_A
2;group_B
```

Dropping and linking the components

Procedure

1. Drop the following components from the Palette to the design workspace: `tPigLoad`, `tPigJoin`, `tPigFilterColumns`, and `tPigStoreResult`.

2. Connect these components in a series using `Row > Pig Combine` connections.
Configuring the components

Loading the main input file

Procedure

1. Double-click tPigLoad to open its Basic settings view.

![Basic settings view]

- **Property Type**: Built-In
- **Schema**: Built-In
- **Edit schema**: unchecked
- **Configuration**: Local
- **Load function**: PigStorage
- **Input file URI**: "D:/Talend/Input/people.csv"
- **Field separator**: ;
- **Compression**: unchecked
- **Force to compress the output data**: unchecked
- **Die on subjob error**: unchecked

2. Click the [...] button next to Edit schema to open the Schema dialog box.
3. Click the [+] button to add columns, name them and define the column types according to the structure of the input file. In this example, the input schema has five columns: id (integer), firstName (string), lastName (string), groupId (integer), and salary (double). Then click OK to validate the setting and close the dialog box.

4. Click Local in the Mode area.

5. Select PigStorage from the Load function list.

6. Fill in the Input file URI field with the full path to the input file, and leave the rest of the setting as they are.

Loading the reference file and setting up an inner join

Procedure

1. Double-click tPigJoin to open its Basic settings view.
2. Click the [...] for the main schema to open the **Schema** dialog box.

3. Check that input schema is correctly retrieved from the preceding component. If needed, click the \(-\rightarrow\) button to copy all the columns of the input schema to the output schema.

4. Click the \([+\)] button under the output panel to add new columns according to the data structure of the reference file, `groupId_ref` (integer) and `groupName` (string) in this example. Then click **OK** to close the dialog box.

5. Click the [...] for the schema lookup flow to open the **Schema** dialog box.
6. Click the [+] button under the output panel to add two columns: `groupId_ref` (integer) and `groupName` (string), and then click **OK** to close the dialog box.

7. In the **Filename** field, specify the full path to the reference file.

8. Click the [+] button under the **Join key** table to add a new line, and select `groupId` and `groupId_ref` respectively from the **Input** and **Lookup** lists to match data from the main input flow with data from the lookup flow based on the group ID.

9. From the **Join Mode** list, select **inner-join**.

**Defining the final output schema and the output file**

**Procedure**

1. Double-click **tPigFilterColumns** to open its **Basic settings** view.

2. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.
3. From the input schema, select the columns you want to include in your result file by clicking them one after another while pressing the **Shift** key, and click the **->** button to copy them to the output schema. Then, click **OK** to validate the schema setting and close the dialog box.

In this example, we want the result file to include all the information except the group IDs.

4. Double-click **tPigStoreResult** to open its **Basic settings** view.

5. Click **Sync columns** to retrieve the schema structure from the preceding component.

6. Fill in the **Result file** field with the full path to the result file, and select the **Remove result file directory if exists** check box.

7. Select **PigStorage** from the **Store function** list, and leave rest of the settings as they are.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the **Run** tab to run the Job.

   The result file includes all the information related to people of group A and group B, except their group IDs.
<table>

</tbody>
</table>

|               | Repository: Select the repository file where the properties are stored. |
|---------------|The properties are stored centrally under the Hadoop Cluster node of the Repository tree. |
|               |The fields that come after are pre-filled in using the fetched data. |
|               |For further information about the Hadoop Cluster node, see the Getting Started Guide. |

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

|               | Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Local</th>
<th>Click this radio button to run Pig scripts in <strong>Local</strong> mode. In this mode, all files are installed and run from your local host and file system.</th>
</tr>
</thead>
</table>
| **Execution engine** | Select the framework you need to use to perform your Pig Job. This Tez mode is available only when you are using one of the following distributions:  
  • Hortonworks: V2.2 +.  
  • Custom: this option allows you to connect to a distribution supporting Tez but not officially supported by *Talend*.  
Before using Tez, ensure that the Hadoop cluster you are using supports Tez. You will need to configure the access to the relevant Tez libraries via the **Advanced settings** view of this component.  
For further information about Pig on Tez, see Apache's related documentation in [https://cwiki.apache.org/confluence/display/PIG/Pig+on+Tez](https://cwiki.apache.org/confluence/display/PIG/Pig+on+Tez). |
| **Distribution and Version** | Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:  
  • If available in this **Distribution** drop-down list, the *Microsoft HD Insight* option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center ([https://help.talend.com](https://help.talend.com)).  
  • If you select *Amazon EMR*, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center ([https://help.talend.com](https://help.talend.com)).  
  • The **Custom** option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by *Talend*.  
1. **Select Import from existing version** to import an officially supported distribution as base and then add other required jar files which the base distribution does not provide.  
2. **Select Import from zip** to import the configuration zip for the custom distribution to be used. This zip file should contain the libraries of the different Hadoop elements and the index file of these libraries.  
In *Talend Exchange*, members of *Talend* community have shared some ready-for-use configuration zip files which you can download from this *Hadoop configuration* list and directly use them in your connection accordingly. However, because of the ongoing evolution of the different Hadoop-
related projects, you might not be able to find the configuration zip corresponding to your distribution from this list; then it is recommended to use the Import from existing version option to take an existing distribution as base to add the jars required by your distribution.

Note that custom versions are not officially supported by Talend. Talend and its community provide you with the opportunity to connect to custom versions from the Studio but cannot guarantee that the configuration of whichever version you choose will be easy, due to the wide range of different Hadoop distributions and versions that are available. As such, you should only attempt to set up such a connection if you have sufficient Hadoop experience to handle any issues on your own.

Note:
In this dialog box, the active check box must be kept selected so as to import the jar files pertinent to the connection to be created between the custom distribution and this component.

For a step-by-step example about how to connect to a custom distribution and share this connection, see Connecting to a custom Hadoop distribution on page 1582.

The other parameters related to the connection to your cluster could be:

- **Use Kerberos authentication:**

  If you are accessing the Hadoop cluster running with Kerberos security, select this check box, then, enter the Kerberos principal name for the NameNode in the field displayed. This enables you to use your user name to authenticate against the credentials stored in Kerberos.

  - If this cluster is a MapR cluster of the version 5.0.0 or later, you can set the MapR ticket authentication configuration in addition or as an alternative by following the explanation in Connecting to a security-enabled MapR on page 1643.

    Keep in mind that this configuration generates a new MapR security ticket for the username defined in the Job in each execution. If you need to reuse an existing ticket issued for the same username, leave both the Force MapR ticket authentication check box and the Use Kerberos authentication check box clear, and then MapR should be able to automatically find that ticket on the fly.

In addition, since this component performs Map/Reduce computations, you also need to authenticate the related services such as the Job history server and the Resource manager or Jobtracker depending on your distribution in the corresponding field. These principals can be found in the configuration files of your distribution. For example, in a CDH4 distribution, the Resource manager principal is set in the yarn-
site.xml file and the Job history principal in the mapred-site.xml file.

This check box is available depending on the Hadoop distribution you are connecting to.

The HBase related principals are required by the HBaseStorage function only.

- **Use a keytab to authenticate:**

  Select the Use a keytab to authenticate check box to log into a Kerberos-enabled system using a given keytab file. A keytab file contains pairs of Kerberos principals and encrypted keys. You need to enter the principal to be used in the Principal field and the access path to the keytab file itself in the Keytab field. This keytab file must be stored in the machine in which your Job actually runs, for example, on a Talend Jobserver.

  Note that the user that executes a keytab-enabled Job is not necessarily the one a principal designates but must have the right to read the keytab file being used. For example, the user name you are using to execute a Job is `user1` and the principal to be used is `guest`; in this situation, ensure that `user1` has the right to read the keytab file to be used.

- **NameNode URI:**

  Type in the location of the NameNode corresponding to the Map/Reduce version to be used. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

- **Resource Manager:**

  Type in the location of the ResourceManager service of your cluster.

  In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first tPigLoad component used in it. The naming convention of a Pig Job in JobHistory is `ProjectName_JobNameVersion_FirstComponentName`.

  Then you can continue to set the following parameters depending on the configuration of the Hadoop cluster to be used (if you leave the check box of a parameter clear, then at runtime, the configuration about this parameter in the Hadoop cluster to be used will be ignored):

  1. Select the Set resourcemanager scheduler address check box and enter the Scheduler address in the field that appears.

  2. Select the Set jobhistory address check box and enter the location of the JobHistory server of the Hadoop cluster to be used. This allows the metrics information of the current Job to be stored in that JobHistory server.

  3. Select the Set staging directory check box and enter this directory defined in your Hadoop cluster for temporary files created by running programs. Typically, this directory can be found under the
yarn.app.mapreduce.am.staging-dir property in the configuration files such as yarn-site.xml or mapred-site.xml of your distribution.

4. Allocate proper memory volumes to the Map and the Reduce computations and the ApplicationMaster of YARN by selecting the Set memory check box in the Advanced settings view.

5. Select the Set Hadoop user check box and enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed.

6. Select the Use datanode hostname check box to allow the Job to access datanodes via their hostnames. This actually sets the dfs.client.use.datanode.hostname property to true. When connecting to a S3N filesystem, you must select this check box.

For further information about these parameters, see the documentation or contact the administrator of the Hadoop cluster to be used.

- User name:

Enter the user name under which you want to execute the Job. Since a file or a directory in Hadoop has its specific owner with appropriate read or write rights, this field allows you to execute the Job directly under the user name that has the appropriate rights to access the file or directory to be processed. Note that this field is available depending on the distribution you are using.

- Parameters related to Qubole:

1. Click the ... button next to the API Token field to enter the authentication token generated for the Qubole user account to be used. For further information about how to obtain this token, see Manage Qubole account from the Qubole documentation.

   This token allows you to specify the user account you want to use to access Qubole. Your Job automatically uses the rights and permissions granted to this user account in Qubole.

2. Select the Cluster label check box and enter the name of the Qubole cluster to be used. If leaving this check box clear, the default cluster is used.

   If you need details about your default cluster, ask the administrator of your Qubole service. You can also read this article from the Qubole documentation to find more information about configuring a default Qubole cluster.

3. Select the Change API endpoint check box and select the region to be used. If leaving this check box clear, the default region is used.

   For further information about the Qubole Endpoints supported on QDS-on-AWS, see Supported Qubole Endpoints on Different Cloud Providers.
4. Configure the connection to the S3 file system to be used to temporarily store the dependencies of your Job so that your Qubole cluster has access to these dependencies.

- **Access key and Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.

  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

- **Bucket name**: enter the name of the bucket in which you want to store the dependencies of your Job. This bucket must already exist on S3.

- **Temporary resource folder**: enter the directory in which you want to store the dependencies of your Job. For example, enter `temp_resources` to write the dependencies in the `/temp_resources` folder in the bucket.

  If this folder already exists at runtime, its contents are overwritten by the upcoming dependencies; otherwise, this folder is automatically created.

- **Region**: specify the AWS region by selecting a region name from the list. For more information about the AWS Region, see [Regions and Endpoints](#).

### WebHCat configuration

Enter the address and the authentication information of the Microsoft HD Insight cluster to be used. For example, the address could be `your_hdinsight_cluster_name.azurehdinsight.net` and the authentication information is your Azure account name: `ychen`. The Studio uses this service to submit the Job to the HD Insight cluster.

In the **Job result folder** field, enter the location in which you want to store the execution result of a Job in the Azure Storage to be used.

### HDInsight configuration

- The **Username** is the one defined when creating your cluster. You can find it in the **SSH + Cluster login** blade of your cluster.

- The **Password** is defined when creating your HDInsight cluster for authentication to this cluster.

### Windows Azure Storage configuration

Enter the address and the authentication information of the Azure Storage account to be used. In this configuration, you do not define where to read or write your business data but define where to deploy your Job only. Therefore always use the Azure Storage system for this configuration.

In the **Container** field, enter the name of the container to be used. You can find the available containers in the **Blob** blade of the Azure Storage account to be used.

In the **Deployment Blob** field, enter the location in which you want to store the current Job and its dependent libraries in this Azure Storage account.
Inspect the classpath for configurations

Select this check box to allow the component to check the configuration files in the directory you have set with the $HADOOP_CONF_DIR variable and directly read parameters from these files in this directory. This feature allows you to easily change the Hadoop configuration for the component to switch between different environments, for example, from a test environment to a production environment.

In this situation, the fields or options used to configure Hadoop connection and/or Kerberos security are hidden.

If you want to use certain parameters such as the Kerberos parameters but these parameters are not included in these Hadoop configuration files, you need to create a file called talend-site.xml and put this file into the same directory defined with $HADOOP_CONF_DIR. This talend-site.xml file should read as follows:

```xml
<!-- Put site-specific property overrides in this file. -->
<configuration>
    <property>
        <name>talend.kerberos.authentication</name>
        <value>kinit</value>
        <description>Set the Kerberos authentication method to use. Valid values are: kinit or keytab. </description>
    </property>
    <property>
        <name>talend.kerberos.keytab.principal</name>
        <value>user@BIGDATA.COM</value>
        <description>Set the keytab's principal name. </description>
    </property>
    <property>
        <name>talend.kerberos.keytab.path</name>
        <value>/kdc/user.keytab</value>
        <description>Set the keytab's path. </description>
    </property>
    <property>
        <name>talend.encryption</name>
        <value>none</value>
        <description>Set the encryption method to use. Valid values are: none or ssl. </description>
    </property>
    <property>
        <name>talend.ssl.trustStore.path</name>
        <value>ssl</value>
        <description>Set SSL trust store path. </description>
    </property>
</configuration>
```
The parameters read from these configuration files override the default ones used by the Studio. When a parameter does not exist in these configuration files, the default one is used.

### Load function

Select a load function for data to be loaded:

- **PigStorage**: Loads data in UTF-8 format.
- **BinStorage**: Loads data in machine-readable format.
- **TextLoader**: Loads unstructured data in UTF-8 format.
- **HCatLoader**: Loads data from HCataLog managed tables using Pig scripts. This function is available only when you have selected HortonWorks as the Hadoop distribution to be used from the Distribution and the Version fields displayed in the Map/Reduce mode. For further information about HCatLoader, see https://hive.apache.org/javadocs/r2.1.1/api/org/apache/hive/hcatalog/pig/HCatLoader.html.
- **HBaseStorage**: Loads data from HBase. Then you need to complete the HBase configuration in the HBase configuration area displayed.
- **SequenceFileLoader**: Loads data of the SequenceFile formats. Then you need to complete the configuration of the file to be loaded in the Sequence Loader Configuration area that appears. This function is for the Map/Reduce mode only.
- **RCFilePigStorage**: Loads data of the RCFile format. This function is for the Map/Reduce mode only.
- **AvroStorage**: Loads Avro files. For further information about AvroStorage, see Apache’s documentation on https://cwiki.apache.org/confluence/display/PIG/AvroStorage. This function is for the Map/Reduce mode only.
- **ParquetLoader**: Loads Parquet file. This function is for the Map/Reduce mode only.
- **Custom**: Loads data using any user-defined load function. To do this, you need to register, in the Advanced settings tab view, the jar file containing the function to be used, and then, in the field displayed next to this Load function field, specify that function.

For example, after registering a jar file called piggybank.jar, you can enter org.apache.pig.piggybank.sto rage.XMLLoader('attr') as (xml:chararray) to use the custom function, XMLLoader contained in that jar file. For further information about this piggybank.jar file, see https://cwiki.apache.org/confluence/display/PIG/PiggyBank.
Note that when the file format to be used is **PARQUET**, you might be prompted to find the specific PARQUET jar file and install it into the Studio.

- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.
- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the **Basic settings** view.

This jar file can be downloaded from Apache’s site. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

<table>
<thead>
<tr>
<th>Input file URI</th>
<th>Fill in this field with the full local path to the input file.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>This field is not available when you select <strong>HCatLoader</strong> from the <strong>Load function</strong> list or when you are using an S3 endpoint.</td>
</tr>
</tbody>
</table>

| Use S3 endpoint | Select this check box to read data from a given Amazon S3 bucket folder.  
Once this **Use S3 endpoint** check box is selected, you need to enter the following parameters in the fields that appear:  
- **S3 bucket name and folder**: enter the bucket name and its folder from which you need to read data. You need to separate the bucket name and the folder name using a slash (/).  
- **Access key** and **Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.  
Note that the format of the S3 file is S3N (S3 Native Filesystem). |

| HCataLog Configuration | Fill the following fields to configure HCataLog managed tables on HDFS (Hadoop distributed file system):  
**Distribution** and **Version**:  
Select the cluster you are using from the drop-down list. The options in the list vary depending on the component you are using. Among these options, the following ones requires specific configuration:  
- If available in this **Distribution** drop-down list, the **Microsoft HD Insight** option allows you to use a Microsoft HD Insight cluster. For this purpose, you need to configure the connections to the HD Insight cluster and the Windows Azure Storage service of that cluster in the areas that are displayed. For detailed explanation about these parameters, search for configuring the connection manually on Talend Help Center (https://help.talend.com). |
- If you select Amazon EMR, you can find more details about how to configure an Amazon EMR cluster in Talend Help Center (https://help.talend.com).
- The Custom option allows you to connect to a cluster different from any of the distributions given in this list, that is to say, to connect to a cluster not officially supported by Talend.

**HCat metastore**: Enter the location of the HCatalog’s metastore, which is actually Hive’s metastore, a system catalog. For further information about Hive and HCatalog, see http://hive.apache.org/.

**Database**: The database in which tables are placed.

**Table**: The table in which data is stored.

**Partition filter**: Fill this field with the partition keys to list partitions by filter.

**Note:**

**HCataLog Configuration area** is enabled only when you select HCatLoader from the Load function list. For further information about the usage of HCataLog, see https://cwiki.apache.org/confluence/display/Hive/HCatalog. For further information about the usage of Partition filter, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.

**Field separator**

Enter character, string or regular expression to separate fields for the transferred data.

**Note:**

This field is enabled only when you select PigStorage from the Load function list.

**Compression**

Select the **Force to compress the output data** check box to compress the data when the data is outputted by tPigStoreResult at the end of a Pig process.

Hadoop provides different compression formats that help reduce the space needed for storing files and speed up data transfer. When you need to write and compress data using the Pig program, by default you have to add a compression format as a suffix to the path pointing to the folder in which you want to write data, for example, /user/ychen/out.bz2. However, if you select this check box, the output data will be compressed even if you do not add any compression format to that path, such as /user/ychen/out.

**Note:** The output path is set in the Basic settings view of tPigStoreResult.

**HBase configuration**

This area is available to the HBaseStorage function. The parameters to be set are:

**Zookeeper quorum**:

Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the zookeeper.znode.parent
property to define the path to the root znode that contains all the znodes created and used by your database; then select the **Set Zookeeper znode parent** check box to define this property.

**Zookeeper client port:**
Type in the number of the client listening port of the Zookeeper service you are using.

**Table name:**
Enter the name of the HBase table you need to load data from.

**Load key:**
Select this check box to load the row key as the first column of the result schema. In this situation, you must have created this column in the schema.

**Mapping:**
Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.

### Sequence Loader configuration

This area is available only to the **SequenceFileLoader** function. Since a SequenceFile record consists of binary key/value pairs, the parameters to be set are:

**Key column:**
Select the Key column of a key/value record.

**Value column**
Select the Value column of a key/value record.

### Die on subJob error

This check box is cleared by default, meaning to skip the row on subjob error and to complete the process for error-free rows.

### Advanced settings

#### Tez lib

Select how the Tez libraries are accessed:

- **Auto install:** at runtime, the Job uploads and deploys the Tez libraries provided by the Studio into the directory you specified in the **Install folder in HDFS** field, for example, `/tmp/usr/tez`.
  
  If you have set the `tez.lib.uris` property in the properties table, this directory overrides the value of that property at runtime. But the other properties set in the properties table are still effective.

- **Use exist:** the Job accesses the Tez libraries already deployed in the Hadoop cluster to be used. You need to enter the path pointing to those libraries in the **Lib path (folder or file)** field.

- **Lib jar:** this table appears when you have selected **Auto install** from the **Tez lib** list and the distribution you are using is **Custom**. In this table, you need to add the Tez libraries to be uploaded.

#### Hadoop Properties

**Talend Studio** uses a default configuration for its engine to perform operations in a Hadoop distribution. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized.
Then at runtime, the customized property or properties will override those default ones.

- Note that if you are using the centrally stored metadata from the Repository, this table automatically inherits the properties defined in that metadata and becomes uneditable unless you change the Property type from Repository to Built-in.

For further information about the properties required by Hadoop and its related systems such as HDFS and Hive, see the documentation of the Hadoop distribution you are using or see Apache’s Hadoop documentation on http://hadoop.apache.org/docs and then select the version of the documentation you want. For demonstration purposes, the links to some properties are listed below:

- Typically, the HDFS-related properties can be found in the hdfs-default.xml file of your distribution, such as http://hadoop.apache.org/docs/r2.6.0/hadoop-project-dist/hadoop-hdfs/hdfs-default.xml.
- Apache also provides a page to list the Hive-related properties: https://cwiki.apache.org/confluence/display/Hive/Configuration+Properties.

### Register jar

Click the [+] button to add rows to the table and from these rows, browse to the jar files to be added. For example, in order to register a jar file called piggybank.jar, click the [+] button once to add one row, then click this row to display the [...] browse button, and click this button to browse to the piggybank.jar file following the Select Module wizard.

### Define functions

Use this table to define UDFs (User-Defined Functions), especially those requiring alias such as Apache DataFu Pig functions, to be executed when loading data.

Click the [+] button to add as many rows as you need and specify an alias and a UDF in the relevant fields for each row.

If your Job includes a tPigMap component, once you have defined UDFs for this component in the tPigMap, this table is automatically filled. Likewise, once you have defined UDFs in this table, the Define functions table in the tPigMap component’s Map Editor is automatically filled.

For information on how to define UDFs when mapping Pig flows, see the section on mapping Big Data flows of the Talend Open Studio for Big Data Getting Started Guide.

For more information on Apache DataFu Pig, see http://datafu.incubator.apache.org/.

### Pig properties

Talend Studio uses a default configuration for its Pig engine to perform operations. If you need to use a custom configuration in a specific situation, complete this table with the property or properties to be customized. Then at runtime, the customized property or properties will override those default ones.

For example, the default_parallel key used in Pig could be set as 20.

### HBaseStorage configuration

Add and set more HBaseStorage loader options in this table. The options are:

- **gt**: the minimum key value;
<table>
<thead>
<tr>
<th><strong>PigLoad</strong></th>
<th><strong>lt</strong>: the maximum key value; <strong>gte</strong>: the minimum key value (included); <strong>lte</strong>: the maximum key value (included); <strong>limit</strong>: maximum number of rows to retrieve per region; <strong>caching</strong>: number of rows to cache; <strong>caster</strong>: the converter to use for reading values out of HBase. For example, HBaseBinaryConverter.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Define the jars to register for HCatalog</strong></td>
<td>This check box appears when you are using tHCatLoader, while you can leave it clear as the Studio registers the required jar files automatically. In case any jar file is missing, you can select this check box to display the Register jar for HCatalog table and set the correct path to that missing jar.</td>
</tr>
<tr>
<td><strong>Path separator in server</strong></td>
<td>Leave the default value of the Path separator in server as it is, unless you have changed the separator used by your Hadoop distribution's host machine for its PATH variable or in other words, that separator is not a colon (:). In that situation, you must change this value to the one you are using in that host.</td>
</tr>
<tr>
<td><strong>Mapred job map memory mb and Mapred job reduce memory mb</strong></td>
<td>You can tune the map and reduce computations by selecting the Set memory check box to set proper memory allocations for the computations to be performed by the Hadoop system. In that situation, you need to enter the values you need in the Mapred job map memory mb and the Mapred job reduce memory mb fields, respectively. By default, the values are both 1000 which are normally appropriate for running the computations. The memory parameters to be set are Map (in Mb), Reduce (in Mb) and ApplicationMaster (in Mb). These fields allow you to dynamically allocate memory to the map and the reduce computations and the ApplicationMaster of YARN.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

## Global Variables

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide.</th>
</tr>
</thead>
</table>
## Usage

### Usage rule
This component is always used to start a Pig process and needs `tPigStoreResult` at the end to output its data.

In the Map/Reduce mode, you need only configure the Hadoop connection for the first `tPigLoad` component of a Pig process (a subjob), and any other `tPigLoad` component used in this process reuses automatically that connection created by that first `tPigLoad` component.

### Prerequisites
The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the *Job Run VM arguments* area of the *Run/Debug* view in the *Preferences* dialog box in the *Window* menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the *Data viewer* to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

### Limitation
Knowledge of Pig scripts is required. If you select HCatLoader as the load function, knowledge of HCatLog DDL (HCatLog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCatLog DDL, see https://cwiki.apache.org/confluence/display/Hive/HCatalog.

## Loading an HBase table

This scenario applies only to *Talend products with Big Data*.

This scenario uses `tPigLoad` and `tPigStoreResult` to read data from HBase and to write them to HDFS.
The HBase table to be used has three columns: id, name and age, among which id and age belong to the column family, family1 and name to the column family, family2.

The data stored in that HBase table are as follows:

```
1;Albert;23
2;Alexandre;24
3;Alfred-Hubert;22
4;Andre;40
5;Didier;28
6;Anthony;35
7;Artus;32
8;Catherine;34
9;Charles;21
10;Christophe;36
11;Christian;67
12;Danniel;54
13;Elisabeth;58
14;Emile;32
15;Gregory;30
```

To replicate this scenario, perform the following operations:

**Linking the components**

**Procedure**

1. In the Integration perspective of Talend Studio, create an empty Job, named hbase_storage for example, from the Job Designs node in the Repository tree view.
   For further information about how to create a Job, see the Talend Studio User Guide.

2. Drop tPigLoad and tPigStoreResult onto the workspace.

3. Connect them using the Row > Pig combine link.

**Configuring tPigLoad**

**Procedure**

1. Double-click tPigLoad to open its Component view.
2. Click the button next to **Edit schema** to open the schema editor.

3. Click the button four times to add four rows and rename them: rowkey, id, name and age. The **rowkey** column put at the top of the schema to store the HBase row key column, but in practice, if you do not need to load the row key column, you can create only the other three columns in your schema.
4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the **Mode** area, select **Map/Reduce**, as we are using a remote Hadoop distribution.

6. In the **Distribution** and the **Version** fields, select the Hadoop distribution you are using. In this example, we are using *HortonWorks Data Platform V1*.

7. In the **Load function** field, select **HBaseStorage**. Then, the corresponding parameters to set appear.

8. In the **NameNode URI** and the **Resource Manager** fields, enter the locations of those services, respectively. If you are using WebHDFS, the location should be `webhdfs://masternode:portnumber`; WebHDFS with SSL is not supported yet.

9. In the **Zookeeper quorum** and the **Zookeeper client port** fields, enter the location information of the Zookeeper service to be used.

10. If the Zookeeper znode parent location has been defined in the Hadoop cluster you are connecting to, you need to select the **Set zookeeper znode parent** check box and enter the value of this property in the field that is displayed.

11. In the **Table name** field, enter the name of the table from which **tPigLoad** reads the data.

12. Select the **Load key** check box if you need to load the HBase row key column. In this example, we select it.

13. In the **Mapping** table, four rows have been added automatically. In the **Column family:qualifier** column, enter the HBase columns you need to map with the schema columns you defined. In this scenario, we put `family1:id` for the *id* column, `family2:name` for the *name* column and `family1:age` for the *age* column.

### Configuring tPigStoreResult

**Procedure**

1. Double-click **tPigStoreResult** to open its **Component** view.
2. In the Result file field, enter the directory where you need to store the result. As tPigStoreResult reuses automatically the connection created by tPigLoad, the path in this scenario is the directory in the machine hosting the Hadoop distribution to be used.

3. Select Remove result directory if exists.

4. In the Store function field, select PigStorage to store the result in the UTF-8 format.

**Executing the Job**

Then you can press F6 run this Job.

Once done, you can verify the result in the HDFS system used.

If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first tPigLoad component used in it. The naming convention of a Pig Job in JobHistory is `ProjectName_JobNameVersion_FirstComponentName`. 
tPigMap

Transforms and routes data from single or multiple sources to single or multiple destinations.

The tPigMap transforms and routes the data in a Pig process. It provides a graphic interface that enables sophisticated configuration of multiple data flows.

Optional map settings

On the input side:

<table>
<thead>
<tr>
<th>Lookup properties</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Join Model</td>
<td>Inner Join;</td>
</tr>
<tr>
<td></td>
<td>Left Outer Join;</td>
</tr>
<tr>
<td></td>
<td>Right Outer Join;</td>
</tr>
<tr>
<td></td>
<td>Full Outer Join.</td>
</tr>
<tr>
<td></td>
<td>The default join option is <strong>Left Outer Join</strong> when you do not activate this option settings panel by displaying it. These options perform the join of two or more flows based on common field values. When more than one lookup tables need joining, the main input flow starts the joining from the first lookup flow, then uses the result to join the second and so on in the same manner until the last lookup flow is joined.</td>
</tr>
<tr>
<td>Join Optimization</td>
<td>None;</td>
</tr>
<tr>
<td></td>
<td>Replicated;</td>
</tr>
<tr>
<td></td>
<td>Skewed;</td>
</tr>
<tr>
<td></td>
<td>Merge.</td>
</tr>
<tr>
<td></td>
<td>The default join option is <strong>None</strong> when you do not activate this option settings panel by displaying it. These options are used to perform more efficient join operations. For example, if you are using the parallelism of multiple reduce tasks, the <strong>Skewed</strong> join can be used to counteract the load imbalance problem if the data to be processed is sufficiently skewed. Each of these options is subject to the constraints explained in Apache's documentation about Pig Latin.</td>
</tr>
<tr>
<td>Custom Partitioner</td>
<td>Enter the Hadoop partitioner you need to use to control the partitioning of the keys of the intermediate map-outputs. For example, enter, in double quotation marks,</td>
</tr>
<tr>
<td></td>
<td>org.apache.pig.test.utils.SimpleCustomPartitioner</td>
</tr>
<tr>
<td></td>
<td>to use the partitioner SimpleCustomPartitioner. For further information about the code of this SimpleCustomPartitioner, see Apache's documentation about Pig Latin. The jar file of this partitioner must have been registered in the Register jar table in the Advanced settings view of the tPigLoad component linked with the tPigMap component to be used.</td>
</tr>
<tr>
<td>Increase Parallelism</td>
<td>Enter the number of reduce tasks. For further information about the parallel features, see Apache's documentation about Pig Latin.</td>
</tr>
</tbody>
</table>
On the output side:

<table>
<thead>
<tr>
<th>Output properties</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Catch Output Reject</em></td>
<td>True; False. This option, once activated, allows you to catch the records rejected by a filter you can define in the appropriate area.</td>
</tr>
<tr>
<td><em>Catch Lookup Inner Join Reject</em></td>
<td>True; False. This option, once activated, allows you to catch the records rejected by the inner join operation performed on the input flows.</td>
</tr>
</tbody>
</table>

**tPigMap Standard properties**

These properties are used to configure tPigMap running in the Standard Job framework.

The Standard tPigMap component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Mapping links display as</th>
<th><strong>Auto</strong>: the default setting is curves links</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Curves</strong>: the mapping display as curves</td>
</tr>
<tr>
<td></td>
<td><strong>Lines</strong>: the mapping displays as straight lines. This last option allows to slightly enhance performance.</td>
</tr>
</tbody>
</table>

| Map editor               | It allows you to define the tPigMap routing and transformation properties. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
</tbody>
</table>
For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Possible uses are from a simple reorganization of fields to the most complex Jobs of data multiplexing or demultiplexing transformation, concatenation, inversion, filtering/splitting and more, in a Pig process.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>The use of <strong>tPigMap</strong> supposes minimum Java and Pig Latin knowledge in order to fully exploit its functionalities. This component is a junction step, and for this reason cannot be a start nor end component in the Job.</td>
</tr>
</tbody>
</table>

### Joining data about road conditions in a Pig process

This scenario applies only to *Talend products with Big Data*.

The Job in this scenario uses two **tPigLoad** components to read data about the traffic conditions and the related events on given roads from a given Hadoop distribution, joins and filters the data using **tPigMap**, and writes the results into that Hadoop distribution using two **tPigStoreResult**.

![Diagram of data processing](image)

The Hadoop distribution to be used is keeping the data about traffic situation such as normal or jam and the data about the traffic-related events such as road work, rain and even no event. In this example, the data to be used reads as follows:
1. The traffic situation data stored in the directory `/user/ychen/tpigmap/date&traffic`:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Road</th>
<th>Status</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-11 00:27:53</td>
<td>Bayshore Freeway</td>
<td>jam</td>
</tr>
<tr>
<td>2013-02-28 07:01:18</td>
<td>Carpinteria Avenue</td>
<td>jam</td>
</tr>
<tr>
<td>2013-01-26 11:27:59</td>
<td>Bayshore Freeway</td>
<td>normal</td>
</tr>
<tr>
<td>2013-03-07 20:48:51</td>
<td>South Highway</td>
<td>jam</td>
</tr>
<tr>
<td>2013-02-07 07:40:10</td>
<td>Lindbergh Blvd</td>
<td>normal</td>
</tr>
<tr>
<td>2013-01-22 17:13:55</td>
<td>Pacific Hwy S</td>
<td>normal</td>
</tr>
<tr>
<td>2013-03-17 23:12:26</td>
<td>Carpinteria Avenue</td>
<td>normal</td>
</tr>
<tr>
<td>2013-01-15 08:06:53</td>
<td>San Diego Freeway</td>
<td>jam</td>
</tr>
<tr>
<td>2013-03-19 15:18:28</td>
<td>Monroe Street</td>
<td>jam</td>
</tr>
<tr>
<td>2013-01-20 05:53:12</td>
<td>Newbury Road</td>
<td>normal</td>
</tr>
</tbody>
</table>

2. The event data stored in the directory `/user/ychen/tpigmap/date&event`:

<table>
<thead>
<tr>
<th>Timestamp</th>
<th>Road</th>
<th>Event</th>
</tr>
</thead>
<tbody>
<tr>
<td>2013-01-11 00:27:53</td>
<td>Bayshore Freeway</td>
<td>road work</td>
</tr>
<tr>
<td>2013-02-28 07:01:18</td>
<td>Carpinteria Avenue</td>
<td>rain</td>
</tr>
<tr>
<td>2013-01-26 11:27:59</td>
<td>Bayshore Freeway</td>
<td>road work</td>
</tr>
<tr>
<td>2013-03-07 20:48:51</td>
<td>South Highway</td>
<td>no event</td>
</tr>
<tr>
<td>2013-02-07 07:40:10</td>
<td>Lindbergh Blvd</td>
<td>second-hand market</td>
</tr>
<tr>
<td>2013-01-22 17:13:55</td>
<td>Pacific Hwy S</td>
<td>no event</td>
</tr>
<tr>
<td>2013-03-17 23:12:26</td>
<td>Carpinteria Avenue</td>
<td>no event</td>
</tr>
<tr>
<td>2013-01-15 08:06:53</td>
<td>San Diego Freeway</td>
<td>second-hand market</td>
</tr>
<tr>
<td>2013-03-19 15:18:28</td>
<td>Monroe Street</td>
<td>road work</td>
</tr>
<tr>
<td>2013-01-20 05:53:12</td>
<td>Newbury Road</td>
<td>no event</td>
</tr>
</tbody>
</table>

For any given moment shown in the timestamps in the data, one row is logged to reflect the traffic situation and another row to reflect the traffic-related event. You need to join the data into one table in order to easily detect how the events on a given road are impacting the traffic.

**Note:**
The data used in this example is a sample with limited size.

To replicate this scenario, ensure that the Studio to be used has the appropriate right to read and write data in that Hadoop distribution and then proceed as follows:

### Linking the components

**Procedure**

1. In the **Integration** perspective of **Talend Studio**, create an empty Job, named *pigweather* for example, from the **Job Designs** node in the **Repository** tree view.
   
   For further information about how to create a Job, see the **Talend Studio User Guide**.

2. Drop two **tPigLoad** components, **tPigMap** and two **tPigStoreResult** onto the workspace.

   The components can be labelled if needed be. In this scenario, we label the two **tPigLoad** components as **traffic** and **event**, respectively, which load accordingly the traffic data and the related event data. Then we label the two **tPigStoreResult** components as **normal** and **jam**, respectively, which write accordingly the results to the Hadoop distribution to be used. For further information about how to label a component, see the **Talend Studio User Guide**.

3. Right-click the **tPigLoad** component labeled **traffic** to connect it to **tPigMap** using the **Row > Pig combine** link from the contextual menu.

4. Repeat this operation to link the **tPigLoad** component labeled **event** to **tPigMap**, too. As this is the second link created, it becomes automatically the lookup link.

5. Use the **Row > Pig combine** link again to connect **tPigMap** to each of the two **tPigStoreResult** components.
You need to name these links in the dialog box popped up once you select the link type from the contextual menu. In this scenario, we name the link to `tPigStoreResult` labeled `normal` as `out` and the link to `tPigStoreResult` labeled `jam` as `reject`.

**Configuring tPigLoad**

**Loading the traffic data**

**Procedure**

1. Double-click the `tPigLoad` labeled `traffic` to open its **Component** view.

2. Click the ⌨️ button next to **Edit schema** to open the schema editor.

3. Click the ➕ button three times to add three rows and in the **Column** column, rename them as `date`, `street` and `traffic`, respectively.
4. Click OK to validate these changes.

5. In the Mode area, select the Map/Reduce option, as we need the Studio to connect to a remote Hadoop distribution.

6. In the Distribution list and the Version field, select the Hadoop distribution to be used. In this example, it is Hortonworks Data Platform V1.0.0.

7. In the Load function list, select the PigStorage function to read the source data, as the data is a structured file in human-readable UTF-8 format.

8. In the NameNode URI and the Resource Manager fields, enter the locations of the master node and the Resource Manager of the Hadoop distribution to be used, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

9. In the Input file URI field, enter the directory where the data about the traffic situation is stored. As explained earlier, the directory in this example is /user/ychen/tpigmap/date&traffic.

10. In the Field separator field, enter ; depending on the separator used by the source data.

**Loading the event data**

**Procedure**

1. Double-click the tPigLoad labeled event to open its Component view.
2. Click the button next to Edit schema to open the schema editor.

3. Click the button three times to add three rows and in the Column column, rename them as date, street and event, respectively.

4. Click OK to validate these changes.

5. In the Mode area, select Map/Reduce.

   As you have configured the connection to the given Hadoop distribution in that first tPigLoad component, traffic, this event component reuses that connection and therefore, the corresponding options in the Distribution and the Version lists have been automatically selected.

6. In the Load function field, select the PigStorage function to read the source data.

7. In the Input file URI field, enter the directory where the event data is stored. As explained earlier, the directory in this example is "/user/ychen/tpigmap/date&event".

Configuring tPigMap

1. Double-click tPigMap to open its Map Editor view.
Creating the output schema

Procedure

1. On the input side (left side) of the Map Editor, each of the two tables represents one of the input flow, the upper one for the main flow and the lower one for the lookup flow.
   
   On the output side (right side), the two tables represent the output flows that you named as out1 and reject earlier.
   
   From the main flow table, drop its three columns onto each of the output flow table.

2. From the lookup flow, drop the event column onto each of the output flow table.
   
   Then from the Schema editor view, you can see the schemas of the both sides have been completed and as well, click each table to display its schema in this view.

Setting the mapping conditions

Procedure

1. On the lookup flow table, click the button to open the setting panel in this table.

2. In the Join Model row, select Left Outer Join to ensure that every record of the main flow is included in this join.

3. On the out1 output flow table, click the button to display the editing field for the filter expression.

4. Enter 'normal'== row1.traffic
   
   This allows tPigMap to output only the traffic records reading normal in the out1 flow.

5. On the reject output flow table, click the button to open the setting panel.

6. In the Catch Output Reject row, select true to output the traffic records reading jam in the reject flow.

7. Click Apply, then click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

Configuring tPigStoreResult

Procedure

1. Double-click the tPigStoreResult labeled normal to open its Component view.
2. In the **Result file** field, enter the directory you need to write the result in. In this scenario, it is `/user/ychen/tpigmap/traffic_normal`, which receives the records reading *normal*.

3. Select **Remove result directory if exists** check box.

4. In the **Store function** list, select **PigStorage** to write the records in human-readable UTF-8 format.

5. In the **Field separator** field, enter `;`.

6. Repeat the same operations to configure the **tPigStoreResult** labeled *jam*, but set the directory, in the **Result file** field, as `/user/ychen/tpigmap/traffic_jam`.

**Results**

**Note:**

If either of the components does not retrieve its schema from **tPigMap**, a warning icon appears. In this case, click the **Sync columns** button to retrieve the schema from the preceding one and once done, the warning icon disappears.

**Executing the Job**

Then you can press **F6** to run this Job.

Once done, verify the results in the Hadoop distribution used.

![File: /user/ychen/tpigmap/traffic_jam/part-r-00000](image)

From the *traffic_jam* records, you can analyze what event is often going on in the meantime of a traffic jam and from the *traffic_normal* records, how the smooth traffic situation is maintained.
If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first PigLoad component used in it. The naming convention of a Pig Job in JobHistory is `ProjectName_JobNameVersion_FirstComponentName`.
tPigReplicate

Performs different operations on the same schema.

The tPigReplicate, used after an input Pig component, duplicates the incoming schema into as many identical output flows as needed.

**tPigReplicate Standard properties**

These properties are used to configure tPigReplicate running in the Standard Job framework.

The Standard tPigReplicate component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: |
|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------- | **Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is not startable (green background); it requires tPigLoad as the input component and expects other Pig components to handle its output flow(s). |

### Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.  
• Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr.  
Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.  
• Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.  
For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |

### Connections

| Connections | Outgoing links (from this component to another):  
Row: Pig combine. This link joins all data processes designed in the Job and executes them simultaneously.  
Incoming links (from one component to this one): |
Replicating a flow and sorting two identical flows respectively

This scenario applies only to Talend products with Big Data.

The Job in this scenario uses Pig components to handle names and states loaded from a given HDFS system. It reads and replicates the input flow, then sorts the two identical flows based on name and state respectively, and writes the results back into that HDFS.

Before starting to replicate this Job, ensure that you have the appropriate right to read and write data in the Hadoop distribution to be used and that Pig is properly installed in that distribution.

Linking the components

Procedure

1. In the **Integration** perspective of Talend Studio, create an empty Job, named *Replicate* for example, from the **Job Designs** node in the **Repository** tree view.
   
   For further information about how to create a Job, see the Talend Studio User Guide.

2. Drop **tPigLoad**, **tPigReplicate**, two **tPigSort** and two **tPigStoreResult** onto the workspace.

   The **tPigLoad** component reads data from the given HDFS system. The sample data used in this scenario reads as follows:

   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
Dwight Roosevelt; Mississippi
Franklin Grant; Nebraska

The location of the data in this scenario is /user/ychen/raw/Name&State.csv.

3. Connect them using the **Row > Pig combine** links.

**Configuring tPigLoad**

**Procedure**

1. Double-click **tPigLoad** to open its **Component** view.

   ![Component view of tPigLoad](image)

   - **Property Type**: Built-In
   - **Schema**: Built-In
   - **Configuration**
     - **Distribution**: HortonWorks
     - **Version**: Hortonworks Data Platform V2.2.0
     - **Execution engine**: Map/Reduce
     - **Load function**: PigStorage
     - **NameNode URI**: hdfs://talend-hdp-all:8020
     - **Resource Manager**: talend-hdp-all:8032
     - **Set jobhistory address**
     - **Set resourcemanager scheduler address**
     - **Set staging directory**
     - **Use datanode hostname**
     - **Authentication**
       - **Use kerberos authentication**
       - **User name**: hdfs
     - **Use S3 endpoint**
     - **Input file URI**: /user/ychen/raw/Name&State.csv
     - **Field separator**: ";"
     - **Compression**
       - **Force to compress the output data**
       - **Die on subjob error**

2. Click the button next to **Edit schema** to open the schema editor.
3. Click the button twice to add two rows and name them Name and State, respectively.

4. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

5. In the Mode area, select Map/Reduce because the Hadoop to be used in this scenario is installed in a remote machine. Once selecting it, the parameters to be set appear.

6. In the Distribution and the Version lists, select the Hadoop distribution to be used.

7. In the Load function list, select PigStorage

8. In the NameNode URI field and the Resource Manager field, enter the locations of the NameNode and the ResourceManager to be used for Map/Reduce, respectively. If you are using WebHDFS, the location should be webhdfs://masternode:portnumber; WebHDFS with SSL is not supported yet.

9. In the Input file URI field, enter the location of the data to be read from HDFS. In this example, the location is /user/ychen/raw/NameState.csv.

10. In the Field separator field, enter the semicolon ;

Configuring tPigReplicate

Procedure

1. Double-click tPigReplicate to open its Component view.

2. Click the button next to Edit schema to open the schema editor to verify whether its schema is identical with that of its preceding component.
Note:
If this component does not have the same schema of the preceding component, a warning icon appears. In this case, click the Sync columns button to retrieve the schema from the preceding one and once done, the warning icon disappears.

Configuring tPigSort

About this task
Two tPigSort components are used to sort the two identical output flows: one based on the Name column and the other on the State column.

Procedure
1. Double-click the first tPigSort component to open its Component view to define the sorting by name.
2. In the Sort key table, add one row by clicking the button under this table.
3. In the Column column, select Name from the drop-down list and select ASC in the Order column.
4. Double-click the other tPigSort to open its Component view to define the sorting by state.
5. In the Sort key table, add one row, then select Name from the drop-down list in the Column column and select ASC in the Order column.

Configuring tPigStoreResult

About this task

Two tPigStoreResult components are used to write each of the sorted data into HDFS.

Procedure

1. Double-click either the first tPigStoreResult component to open its Component view to write the data sorted by name.

2. In the Result file field, enter the directory where the data will be written. This directory will be created if it does not exist. In this scenario, we put /user/ychen/sort/tPigreplicate/byName.csv.

3. Select Remove result directory if exists.

4. In the Store function list, select PigStorage.

5. In the Field separator field, enter the semicolon ;.

6. Do the same for the other tPigStoreResult component but set another directory for the data sorted by state. In this scenario, it is /user/ychen/sort/tPigreplicate/byState.csv.
Executing the Job

About this task
Then you can run this Job.

Procedure
Press F6 to run this Job.

Results
Once done, browse to the locations where the results were written in HDFS.
The following image presents the results sorted by name:

File: /user/ychen/sort/tPigreplicate/byName.csv/part-r-00000

The following image presents the results sorted by state:
If you need to obtain more details about the Job, it is recommended to use the web console of the Jobtracker provided by the Hadoop distribution you are using.

In JobHistory, you can easily find the execution status of your Pig Job because the name of the Job is automatically created by concatenating the name of the project that contains the Job, the name and version of the Job itself and the label of the first PigLoad component used in it. The naming convention of a Pig Job in JobHistory is ProjectName_JobNameVersion_FirstComponentName.
**tPigSort**

Sorts relation based on one or more defined sort keys.

**tPigSort Standard properties**

These properties are used to configure tPigSort running in the Standard Job framework.

The Standard tPigSort component belongs to the Big Data and the Processing families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

### Basic settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in**           | The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide.                                                                                          |
| **Repository**         | The schema already exists and is stored in the Repository, hence can be reused in various projects and Job designs. Related topic: see Talend Studio User Guide.                                                |
| **Sort key**           | Click the **Add** button beneath the **Sort key** table to add one or more lines to specify column and sorting order for each sort key.                                                                     |

### Advanced settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Increase parallelism</strong></td>
<td>Select this check box to set the number of reduce tasks for the MapReduce Jobs</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>
Global Variables

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

Usage

| Usage rule | This component is commonly used as intermediate step together with input component and output component. |

Prerequisites

| Prerequisites | The Hadoop distribution must be properly installed, so as to guarantee the interaction with *Talend Studio*. The following list presents MapR related information for example.  
- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR's documentation, the library or libraries of a MapR client corresponding to each OS version can be found under `MAPR_INSTALL\ hadoop\hadoop-VERSION\lib\native`. For example, the library for Windows is `\lib\native\MapRClient.dll` in the MapR client jar file. For further information, see the following link from MapR: [http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr](http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr).

Without adding the specified library or libraries, you may encounter the following error: `no MapRClient in java.library.path`.

- Set the `-Djava.library.path` argument, for example, in the **Job Run VM arguments** area of the **Run/Debug** view in the **Preferences** dialog box in the **Window** menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the **Data viewer** to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using. |

Limitation

| Limitation | Knowledge of Pig scripts is required. |

Sorting data in ascending order

This scenario applies only to *Talend products with Big Data.*
This scenario describes a three-component Job that sorts rows of data based on one or more sorting conditions and stores the result into a local file.

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: tPigSort, tPigLoad, tPigStoreResult.
2. Connect tPigLoad to tPigFilterRow using a Row > Pig Combine connection.
3. Connect tPigFilterRow to tPigStoreResult using a Row > Pig Combine connection.

Loading the data

Procedure

1. Double-click tPigLoad to open its Basic settings view.
2. Click the [...] button next to Edit schema to add columns for tPigLoad.
3. Click the \([+]\) button to add Name, Country and Age and click OK to save the setting.

4. Select Local from the Mode area.

5. Fill in the Input filename field with the full path to the input file.
   In this scenario, the input file is CustomerList that contains rows of names, country names and age.

6. Select PigStorage from the Load function list.

7. Leave rest of the settings as they are.

**Setting the sorting condition**

**Procedure**

1. Double-click tPigSort to open its Basic settings view.

2. Click Sync columns to retrieve the schema structure from the preceding component.

3. Click the \([+]\) button beneath the Sort key table to add a new sort key. Select Age from the Column list and select ASC from the Order list.
   This sort key will sort the data in CustomerList in ascending order based on Age.

**Saving the data to a local file**

**Procedure**

1. Double-click tPigStoreResult to open its Basic settings view.
2. Click **Sync columns** to retrieve the schema structure from the preceding component.

3. Select **Remove result directory if exists**.

4. Fill in the **Result file** field with the full path to the result file.
   
   In this scenario, the result of filter is saved in **Lucky_Customer** file.

5. Select **PigStorage** from the **Store function** list.

6. Leave rest of the settings as they are.

**Executing the Job**

Save your Job and press **F6** to run it.

```
Lucky_Customer
```

Romeo;UK;19
Silvia;Spain;20
Billy;Canada;21
Mike;USA;22
Manik;Marta;23
Juan;Cuba;23
Bill;USA;24
Natasha;Russia;25
Huamei;China;26
Ahmad;KSA;27
Fernicka;Canada;27
Selena;Mexico;27
Pantalion;Peru;28
Didi;Brazil;28
Julio;Peru;29
Zidane;Algeria;29
Nancy;Lebanan;31
Simao;Brazil;33
Eminem;USA;35
Ricky;PuertoRico;37
Mario;PuertoRico;49
Bob;Jamaica;55
Gaddafi;Lybia;69
Toyota;Japan;75
Name;Country;Age
```

The **Lucky_Customer** file is generated containing the data in ascending order based on **Age**.
**tPigStoreResult**

Stores the result of your Pig Job into a defined data storage space.

**tPigStoreResult Standard properties**

These properties are used to configure tPigStoreResult running in the Standard Job framework.

The Standard tPigStoreResult component belongs to the Big Data and the Processing families.

The component in this framework is available in all [Talend products with Big Data](https://www.talend.com/products/big-data) and in [Talend Data Fabric](https://www.talend.com/products/data-fabric).

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Repository</strong> or <strong>Built-in</strong>. The <strong>Repository</strong> option allows you to reuse the connection properties centrally stored under the <strong>Hadoop cluster node</strong> of the <strong>Repository</strong> tree. Once selecting it, the <strong>...</strong> button appears, then you can click it to display the list of the stored properties and from that list, select the properties you need to use. Once done, the appropriate parameters are automatically set. Otherwise, if you select <strong>Built-in</strong>, you need to manually set each of the parameters.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://www.talend.com/products/big-data).

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://www.talend.com/products/big-data).

**Use S3 endpoint**

Select this check box to write data into a given Amazon S3 bucket folder.
Once this **Use S3 endpoint** check box is selected, you need to enter the following parameters in the fields that appear:

- **S3 bucket name and folder**: enter the bucket name and its folder in which you need to write data. You need to separate the bucket name and the folder name using a slash (/).
- **Access key** and **Secret key**: enter the authentication information required to connect to the Amazon S3 bucket to be used.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Note that the format of the S3 file is S3N (S3 Native Filesystem).

<table>
<thead>
<tr>
<th>Result folder URI</th>
<th>Select the path to the result file in which data is stored.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Remove result directory if exists</td>
<td>Select this check box to remove an existing result directory.</td>
</tr>
</tbody>
</table>

**Note:**
This check box is disabled when you select **HCatStorer** from the **Store function** list.

<table>
<thead>
<tr>
<th>Store function</th>
<th>Select a store function for data to be stored:</th>
</tr>
</thead>
<tbody>
<tr>
<td>PigStorage</td>
<td>Stores data in UTF-8 format.</td>
</tr>
<tr>
<td>BinStorage</td>
<td>Stores data in machine-readable format.</td>
</tr>
<tr>
<td>PigDump</td>
<td>Stores data as tuples in human-readable UTF-8 format.</td>
</tr>
<tr>
<td>HCatStorer</td>
<td>Stores data in HCatalog managed tables using Pig scripts.</td>
</tr>
<tr>
<td>HBaseStorage</td>
<td>Stores data in HBase. Then you need to complete the HBase configuration in the HBase configuration area displayed.</td>
</tr>
<tr>
<td>SequenceFileStorage</td>
<td>Stores data of the SequenceFile formats. Then you need to complete the configuration of the file to be stored in the Sequence Storage Configuration area that appears.</td>
</tr>
<tr>
<td>RCFilePigStorage</td>
<td>Stores data of the RCFile format.</td>
</tr>
<tr>
<td>AvroStorage</td>
<td>Stores Avro files. For further information about AvroStorage, see Apache’s documentation on <a href="https://cwiki.apache.org/confluence/display/PIG/AvroStorage">https://cwiki.apache.org/confluence/display/PIG/AvroStorage</a>.</td>
</tr>
<tr>
<td>ParquetStorer</td>
<td>Stores Parquet files. Then from the Associate tPigLoad component list, you need to select the tPigLoad component in which the connection to the MapReduce cluster to be used is defined. Then from the Compression list that appears, select the compression mode you need to use to handle the PARQUET file. The default mode is <strong>Uncompressed</strong>.</td>
</tr>
<tr>
<td>Custom</td>
<td>Stores data using any user-defined store function. To do this, you need to register, in the Advanced settings tab view, the jar file containing the function to be used, and then, in the field displayed next to this Store function field, specify that function.</td>
</tr>
</tbody>
</table>
Note that when the file format to be used is **PARQUET**, you might be prompted to find the specific PARQUET jar file and install it into the Studio.

- When the connection mode to Hive is **Embedded**, the Job is run in your local machine and calls this jar installed in the Studio.
- When the connection mode to Hive is **Standalone**, the Job is run in the server hosting Hive and this jar file is sent to the HDFS system of the cluster you are connecting to. Therefore, ensure that you have properly defined the NameNode URI in the corresponding field of the Basic settings view.

This jar file can be downloaded from Apache’s site. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### HCatalog Configuration

Fill the following fields to configure HCatalog managed tables on HDFS (Hadoop distributed file system):

- **Distribution** and **Version**: Select the Hadoop distribution to which you have defined the connection in the tPigLoad component, used in the same Pig process of the active tPigStoreResult.

  If that tPigLoad component connects to a custom Hadoop distribution, you must select **Custom** for this tPigStoreResult component, too. Then the Custom jar table appears, in which, you need to add only the jar files required by the selected Store function.

- **HCat metastore**: Enter the location of the HCatalog’s metastore, which is actually Hive’s metastore.

- **Database**: The database in which tables are placed.

- **Table**: The table in which data is stored.

- **Partition filter**: Fill this field with the partition keys to list partitions by filter.

**Note:**

**HCatalog Configuration area** is enabled only when you select HCatStorer from the Store function list. For further information about the usage of HCatalog, see https://cwiki.apache.org/confluence/display/Hive/HCatalog. For further information about the usage of Partition filter, see https://cwiki.apache.org/confluence/display/HCATALOG/Design+Document+-+Java+APIs+for+HCatalog+DDL+Commands.

### HBase configuration

This area is available to the HBaseStorage function. The parameters to be set are:

- **Distribution** and **Version**: Select the Hadoop distribution to which you have defined the connection in the tPigLoad component, used in the same Pig process of the active tPigStoreResult.

  If that tPigLoad component connects to a custom Hadoop distribution, you must select **Custom** for this tPigStoreResult component, too. Then the Custom jar table appears, in which, you need to add only the jar files required by the selected Store function.
### Zookeeper quorum:
Type in the name or the URL of the Zookeeper service you use to coordinate the transaction between your Studio and your database. Note that when you configure the Zookeeper, you might need to explicitly set the `zookeeper.znode.parent` property to define the path to the root znode that contains all the znodes created and used by your database; then select the **Set Zookeeper znode parent** check box to define this property.

### Zookeeper client port:
Type in the number of the client listening port of the Zookeeper service you are using.

### Table name:
Enter the name of the HBase table you need to store data in. The table must exist in the target HBase.

### Row key column:
Select the column used as the row key column of the HBase table.

### Store row key column to Hbase column:
Select this check box to make the row key column an HBase column belonging to a specific column family.

### Mapping:
Complete this table to map the columns of the table to be used with the schema columns you have defined for the data flow to be processed.

The **Column** column of this table is automatically filled once you have defined the schema; in the **Family name** column, enter the column families you want to create or use to group the columns in the **Column** column. For further information about a column family, see Apache documentation at [Column families](#).

### Field separator
Enter character, string or regular expression to separate fields for the transferred data.

**Note:**
This field is enabled only when you select **PigStorage** from the **Store function** list.

### Sequence Storage configuration
This area is available only to the **SequenceFileStorage** function. Since a SequenceFile record consists of binary key/value pairs, the parameters to be set are:

**Key column:**
Select the Key column of a key/value record.

**Value column**
Select the Value column of a key/value record.

### Advanced settings

**Register jar**
Click the [*] button to add rows to the table and from these rows, browse to the jar files to be added. For example, in order to register a jar file called `piggybank.jar`, click the [*] button once to add one row, then click this row to display
the [...] browse button, and click this button to browse to the piggybank.jar file following the Select Module wizard.

**HBaseStorage configuration**

Add and set more HBaseStorage storer options in this table. The options are:
- **loadKey**: enter true to store the row key as the first column of the result schema, otherwise, enter false;
- **gt**: the minimum key value;
- **lt**: the maximum key value;
- **gte**: the minimum key value (included);
- **lte**: the maximum key value (included);
- **limit**: maxum number of rows to retrieve per region;
- **caching**: number of rows to cache;
- **caster**: the converter to use for writing values to HBase. For example, Utf8StorageConverter.

**Define the jars to register**

This check box appears when you are using tHCatStorer, while by default, you can leave it clear as the Studio registers the required jar files automatically. In case any jar file is missing, you can select this check box to display the Register jar for HCatalog table and set the correct path to that missing jar.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

**Usage rule**

This component is always used to end a Pig process and needs **tPigLoad** at the beginning of that chain to provide data

This component reuses automatically the connection created by the **tPigLoad** component in that Pig process.

Note that if you use Hortonworks Data Platform V2.0.0, the type of the operating system for running the distribution and a **Talend** Job must be the same, such as Windows or Linux. Otherwise, you have to use **Talend** Jobserver to execute the Job in the same type of operating system in
Prerequisites

The Hadoop distribution must be properly installed, so as to guarantee the interaction with Talend Studio. The following list presents MapR related information for example.

- Ensure that you have installed the MapR client in the machine where the Studio is, and added the MapR client library to the PATH variable of that machine. According to MapR’s documentation, the library or libraries of a MapR client corresponding to each OS version can be found under MAPR_INSTALL\hadoop\hadoop-VERSION\lib\native. For example, the library for Windows is \lib\native\MapRClient.dll in the MapR client jar file. For further information, see the following link from MapR: http://www.mapr.com/blog/basic-notes-on-configuring-eclipse-as-a-hadoop-development-environment-for-mapr. Without adding the specified library or libraries, you may encounter the following error: no MapRClient in java.library.path.
- Set the -Djava.library.path argument, for example, in the Job Run VM arguments area of the Run/Debug view in the Preferences dialog box in the Window menu. This argument provides to the Studio the path to the native library of that MapR client. This allows the subscription-based users to make full use of the Data viewer to view locally in the Studio the data stored in MapR.

For further information about how to install a Hadoop distribution, see the manuals corresponding to the Hadoop distribution you are using.

Limitation

Knowledge of Pig scripts is required. If you select HCatStorer as the store function, knowledge of HCatLog DDL (HCatLog Data Definition Language, a subset of Hive Data Definition Language) is required. For further information about HCatLog DDL, see https://cwiki.apache.org/confluence/display/Hive/HCatalog.

Related Scenario

- Related scenario in which tPigStoreResult uses the Local mode, see Sorting data in ascending order on page 2958 of tPigSort.
- Related scenario in which tPigStoreResult uses the Map/Reduce mode, see Loading an HBase table on page 2933.
tPivotToColumnsDelimited

Fine-tunes the selection of data to output.

The tPivotToColumnsDelimited outputs data based on an aggregation operation carried out on a pivot column.

**tPivotToColumnsDelimited Standard properties**

These properties are used to configure tPivotToColumnsDelimited running in the Standard Job framework.

The Standard tPivotToColumnsDelimited component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pivot column</td>
<td>Select the column from the incoming flow that will be used as pivot for the aggregation operation.</td>
</tr>
<tr>
<td>Aggregation column</td>

</tbody>
</table>
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an input flow.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <strong>Install</strong> button on the <strong>Component</strong> tab view. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

**Using a pivot column to aggregate data**

The following scenario describes a Job that aggregates data from a delimited input file, using a defined pivot column.

**Dropping and linking components**

**Procedure**

1. Drop the following component from the **Palette** to the design workspace: **tFileInputDelimited**, **tPivotToColumnsDelimited**.
2. Link the two components using a **Row > Main** connection.

**Configuring the components**

**Set the input component**

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.
2. Browse to the input file to fill out the **File Name** field. The file to use as input file is made of 3 columns, including: **ID**, **Question** and the corresponding **Answer**

<table>
<thead>
<tr>
<th>Id</th>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Name</td>
<td>Juan</td>
</tr>
<tr>
<td>2</td>
<td>Name</td>
<td>Jean</td>
</tr>
<tr>
<td>3</td>
<td>Name</td>
<td>John</td>
</tr>
<tr>
<td>1</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>F</td>
</tr>
<tr>
<td>3</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>1</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>Surgery</td>
<td>No</td>
</tr>
<tr>
<td>3</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>1</td>
<td>Age</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Age</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>Age</td>
<td>42</td>
</tr>
<tr>
<td>1</td>
<td>Name</td>
<td>Mary</td>
</tr>
</tbody>
</table>

3. Define the **Row** and **Field** separators, in this example, respectively: carriage return and semi-colon
4. As the file contains a header line, define it also.
5. Set the schema describing the three columns: **ID**, **Questions**, **Answers**.

**Set the output component**

**Procedure**

1. Double-click the **tPivotToColumnsDelimited** component to open its **Basic settings** view.
2. In the **Pivot column** field, select the pivot column from the input schema. This is often the column presenting most duplicates (pivot aggregation values).

3. In the **Aggregation column** field, select the column from the input schema that should get aggregated.

4. In the **Aggregation function** field, select the function to be used in case duplicates are found out.

5. In the **Group by** table, add an Input column, that will be used to group by the aggregation column.

6. In the **File Name** field, browse to the output file path. And on the **Row** and **Field separator** fields, set the separators for the aggregated output rows and data.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>Name</th>
<th>Gender</th>
<th>Surgery</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mary</td>
<td>M</td>
<td>Yes</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Jean</td>
<td>M</td>
<td>No</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>John</td>
<td>F</td>
<td>Yes</td>
<td>42</td>
</tr>
</tbody>
</table>

The output file shows the newly aggregated data.
tPOP

Fetches one or more email messages from a server using the POP3 or IMAP protocol.

tPOP uses the POP or IMAP protocol to connect to a specific email server. Then it fetches one or more email messages and writes the recovered information in specified files. Parameters in the Advanced settings view allows you to use filters on your selection.

**tPOP Standard properties**

These properties are used to configure tPOP running in the Standard Job framework.

The Standard tPOP component belongs to the Internet family.

The component in this framework is available in all [Talend products](https://www.talend.com).

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>IP address of the email server you want to connect to.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Port number of the email server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication data for the email server.</td>
</tr>
<tr>
<td><strong>Username</strong></td>
<td>Enter the username you use to access your email box.</td>
</tr>
<tr>
<td><strong>Password</strong></td>
<td>Enter the password you use to access your email box.</td>
</tr>
<tr>
<td><strong>Output directory</strong></td>
<td>Enter the path to the file in which you want to store the email messages you retrieve from the email server, or click the three-dot button next to the field to browse to the file.</td>
</tr>
<tr>
<td><strong>Filename pattern</strong></td>
<td>Define the syntax of the names of the files that will hold each of the email messages retrieved from the email server, or press Ctrl+Space to display the list of predefined patterns.</td>
</tr>
<tr>
<td><strong>Retrieve all emails?</strong></td>
<td>Select this check box to retrieve all email messages present on the specified server.</td>
</tr>
<tr>
<td><strong>Number of emails to retrieve</strong></td>
<td>Enter the number of email messages you want to retrieve. This field is available only when the Retrieve all emails? check box is cleared.</td>
</tr>
<tr>
<td><strong>Newer email first</strong></td>
<td>Select this check box to retrieve the most recent email messages according to the number specified in the Number of emails to retrieve field, and the email messages will be returned in chronological order. This check box is available only when the Retrieve all emails? check box, which is selected by default, is cleared.</td>
</tr>
<tr>
<td><strong>Delete emails from server</strong></td>
<td>Select this check box if you do not want to keep the retrieved email messages on the server.</td>
</tr>
</tbody>
</table>
### Choose the protocol

From the list, select the protocol to be used to retrieve the email messages from the server. This protocol is the one used by the email server. If you choose the imap protocol, you will be able to select the folder from which you want to retrieve your emails.

### Use SSL

Select this check box if your email server uses this protocol for authentication and communication confidentiality.

**Note:**
This option is obligatory for users of Gmail.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a job level as well as at each component level.

**Filter**

Click the plus button to add as many lines as needed to filter email messages and retrieve only a specific selection:

- **Filter item**: select one of the following filter types from the list:
  - **From**: email messages are filtered according to the sender email address.
  - **To**: email messages are filtered according to the recipient email address.
  - **Subject**: email messages are filtered according to the message subject matter.
  - **Before date**: email messages are filtered by the sending or receiving date. All messages before the set date are retrieved.
  - **After date**: email messages are filtered by the sending or receiving date. All messages after the set date are retrieved.

- **Pattern**: press Ctrl+Space to display the list of available values. Select the value to use for each filter.

**Filter condition relation**

Select the type of logical relation you want to use to combine the specified filters:

- **and**: the conditions set by the filters are combined together, the research is more restrictive.
- **or**: the conditions set by the filters are independent, the research is large.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable.
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**NB_EMAIL**: the number of emails received. This is an **After** variable and it returns an integer.

**CURRENT_FILE**: the current file name. This is a **Flow** variable and it returns a string.

**CURRENT_FILEPATH**: the current file path. This is a **Flow** variable and it returns a string.

A **Flow** variable functions during the execution of a component while an **After** variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component does not handle data flow, it can be used alone.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>When the <strong>Use SSL</strong> check box or the <strong>imap</strong> protocol is selected, <strong>tPOP</strong> cannot work with IBM Java 6.</td>
</tr>
</tbody>
</table>

## Retrieving a selection of email messages from an email server

This scenario is a one-component Job that retrieves a predefined number of email messages from an email server.

- **Drop the tPOP component from the Palette to the design workspace.**
- **Double click tPOP to display the **Basic settings** view and define the component properties.**
- **Enter the email server IP address and port number in the corresponding fields.**
- **Enter the username and password for your email account in the corresponding fields.** In this example, the email server is called **Free**.
• In the **Output directory** field, enter the path to the output directory manually, or click the three-dot button next to the field and browse to the output directory where the email messages retrieved from the email server are to be stored.

• In the **Filename pattern** field, define the syntax you want to use to name the output files that will hold the messages retrieved from the email server, or press **Ctrl+Space** to display a list of predefined patterns. The syntax used in this example is the following: `TalendDate.getDate("yyyyMMdd-hhmmss") + "_" + (counter_tPOP_1 + 1) + ".txt"`. The output files will be stored as .txt files and are defined by date, time and arrival chronological order.

• Clear the **Retrieve all emails?** field and in the **Number of emails to retrieve** field, enter the number of email messages you want to retrieve, 10 in this example.

• Select the **Delete emails from server** check box to delete the email messages from the email server once they are retrieved and stored locally.

• In the **Choose the protocol** field, select the protocol type you want to use. This depends on the protocol used by the email server. Certain email suppliers, like **Gmail**, use both protocols. In this example, the protocol used is **pop3**.

• Save your Job and press **F6** to execute it.

The **tPOP** component retrieves the 10 recent messages from the specified email server. In the **tPOP** directory stored locally, a .txt file is created for each retrieved message. Each file holds the metadata of the email message headings (sender’s address, recipient’s address, subject matter) in addition to the message content.
tPostgresPlusBulkExec

Improves performance during Insert operations to a DB2 database.

The tPostgresPlusBulkExec executes the Insert action on the data provided.

The tPostgresplusOutputBulk and tPostgresplusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

tPostgresPlusBulkExec Standard properties

These properties are used to configure tPostgresPlusBulkExec running in the Standard Job framework.

The Standard tPostgresPlusBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **DB Version** | List of database versions. |
| **Host** | Database server IP address |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database |
| **Schema** | Name of the DB schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | On the table defined, you can perform one of the following operations:  
  - None: No operation is carried out.  
  - Drop and create table: The table is removed and created again.  
  - Create table: The table does not exist and gets created.  
  - Create table if not exists: The table is created if it does not exist.  
  - Drop table if exists and create: The table is removed if it already exists and created again.  
  - Clear table: The table content is deleted.  
  - Truncate table: The table content is deleted. You do not have the possibility to rollback the operation. |
| **File Name** | Name of the file to be loaded. **Warning:** This file is located on the machine specified by the URI in the Host field so it should be on the same machine as the database server. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |

**Advanced settings**

| Additional JDBC Parameters | Specify additional JDBC parameters for the database connection being created. This property is not available when the Use an existing connection check box in the Basic settings view is selected. |
| Action | Select the action to be carried out Bulk insert Bulk update Depending on the action selected, the required information varies. |
| Field terminated by | Character, string or regular expression to separate fields. |
| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This dedicated component offers performance and flexibility of DB2 query handling. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different... |
Related scenarios

For **tPostgresPlusBulkExec** related topics, see:

- Inserting transformed data in MySQL database on page 2508.
- Truncating and inserting file data into an Oracle database on page 2716.
tPostgresPlusClose

Closes the transaction committed in the connected PostgresPlus database.

**tPostgresPlusClose Standard properties**

These properties are used to configure tPostgresPlusClose running in the Standard Job framework.

The Standard tPostgresPlusClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tPostgresPlusConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with PostgresPlus components, especially with **tPostgresPlusConnection** and **tPostgresPlusCommit**. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
**tPostgresPlusCommit**

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresPlusCommit validates the data processed through the Job into the connected DB.

**tPostgresPlusCommit Standard properties**

These properties are used to configure tPostgresPlusCommit running in the Standard Job framework.

The Standard tPostgresPlusCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

---

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tPostgresPlusCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

---

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

---

### Usage

| Usage rule | This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusConnection and tPostgresPlusRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned. |
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tPostgresPlusCommit related scenario, see Inserting data in mother/daughter tables on page 2452
tPostgresPlusConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresPlusConnection opens a connection to the database for a current transaction.

tPostgresPlusConnection Standard properties

These properties are used to configure tPostgresPlusConnection running in the Standard Job framework.

The Standard tPostgresPlusConnection component belongs to the Databases and the ELT families. The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of database versions.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter your DB authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database</td>
</tr>
</tbody>
</table>
connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |
| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

### Usage

| **Usage rule** | This component is more commonly used with other **tPostgresPlus** components, especially with the **tPostgresPlusCommit** and **tPostgresPlusRollback** components. |

### Related scenario

For **tPostgresPlusConnection** related scenario, see **tMysqlConnection** on page 2451.
tPostgresPlusInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

The tPostgresPlusInput reads a database and extracts fields based on a query.

**tPostgresPlusInput Standard properties**

These properties are used to configure tPostgresPlusInput running in the Standard Job framework.

The Standard tPostgresPlusInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>

</tr>
<tr>
<td>tStat Catcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>QUERY</strong>: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Postgresql databases.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Related scenarios**

For related scenarios, see:
tPostgresPlusOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

The tPostgresPlusOutput writes, updates, makes changes or suppresses entries in a database.

**tPostgresPlusOutput Standard properties**

These properties are used to configure tPostgresPlusOutput running in the Standard Job framework.

The Standard tPostgresPlusOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

---

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="icon.png" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view. For more information about setting up and storing database connection parameters, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide.*

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>

<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None:</strong> No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table:</strong> The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table:</strong> The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists:</strong> The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create:</strong> The table is removed if already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table:</strong> The table content is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Truncate table:</strong> The table content is deleted. You don’t have the possibility to rollback the operation.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td><strong>Insert:</strong> Add new entries to the table. If duplicates are found, Job stops.</td>
</tr>
<tr>
<td></td>
<td><strong>Update:</strong> Make changes to existing entries</td>
</tr>
</tbody>
</table>
|                  | **Insert or update:** Insert a new record. If the record with the given reference already exists, an update would be made.
**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.*

---

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

---

### Built-In

You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

---

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

---

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection being created. This property is not available when the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong> view is selected.</td>

<tr>
<td><strong>Commit every</strong></td>
<td>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</td>
</tr>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column.</td>
</tr>
<tr>
<td><strong>SQL expression</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column</strong></td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>Enable debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>Support null in &quot;SQL WHERE&quot; statement</strong></td>
<td>Select this check box if you want to deal with the Null values contained in a DB table.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>Ensure that the Nullable check box is selected for the corresponding columns in the schema.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing.</td>
</tr>
<tr>
<td><strong>Note</strong></td>
<td>This check box is available only when you have selected the <strong>Insert</strong>, the <strong>Update</strong> or the <strong>Delete</strong> option in the <strong>Action on data</strong> field.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the <strong>Use batch mode</strong> check box is selected.</td>
</tr>
</tbody>
</table>
**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_DELETED: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>QUERY: the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

**Usage**

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a PostgresPlus database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see *Retrieving data in error with a Reject link* on page 2500.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2472 and Reading data from different
Related scenarios

For tPostgresPlusOutput related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2492.
tPostgresPlusOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the PostgresPlus database.

The tPostgresPlusOutputBulk writes a file with columns based on the defined delimiter and the PostgresPlus standards.

The tPostgresPlusOutputBulk and tPostgresplusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

tPostgresPlusOutputBulk Standard properties

These properties are used to configure tPostgresPlusOutputBulk running in the Standard Job framework.

The Standard tPostgresPlusOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</tbody>
</table>
Usage

| Usage rule | This component is to be used along with `tPostgresPlusBulkExec` component. Used together they offer gains in performance while feeding a PostgresPlus database. |

**Related scenarios**

For use cases in relation with `tPostgresPlusOutputBulk`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tPostgresPlusOutputBulkExec

Improves performance during Insert operations to a PostgresPlus database.

The tPostgresPlusOutputBulkExec executes the Insert action on the data provided.

The tPostgresPlusOutputBulk and tPostgresPlusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component.

tPostgresPlusOutputBulkExec Standard properties

These properties are used to configure tPostgresPlusOutputBulkExec running in the Standard Job framework.

The Standard tPostgresPlusOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</tbody>
</table>

### Related scenarios

For use cases in relation with tPostgresPlusOutputBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tPostgresPlusRollback

Avoids to commit part of a transaction involuntarily.
The tPostgresPlusRollback cancels the transaction committed in the connected DB.

**tPostgresPlusRollback Standard properties**

These properties are used to configure tPostgresPlusRollback running in the Standard Job framework.
The Standard tPostgresPlusRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusConnection and tPostgresPlusCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different databases on page 2473. |
Related scenarios

For **tPostgresPlusRollback** related scenario, see *Rollback from inserting data in mother/daughter tables* on page 2455.
tPostgresPlusRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresPlusRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tPostgresPlusRow Standard properties**

These properties are used to configure tPostgresPlusRow running in the Standard Job framework.

The Standard tPostgresPlusRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see **Talend Studio User Guide**.

### Table name

Name of the table to be read.

### Query type

Either **Built-in** or **Repository**.

**Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder

**Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

### Query

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-
free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Specify additional JDBC parameters for the database connection being created. This property is not available when the Use an existing connection check box in the Basic settings view is selected.</th>
</tr>
</thead>
</table>
| Propagate QUERY’s recordset | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.  
  **Note:**  
  This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet. |
| Use PreparedStatement | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by "?" in the SQL instruction of the Query field in the Basic Settings tab.  
  **Parameter Index:** Enter the parameter position in the SQL instruction.  
  **Parameter Type:** Enter the parameter type.  
  **Parameter Value:** Enter the parameter value.  
  **Note:**  
  This option is very useful if you need to execute the same query several times. Performance levels are increased |
| Commit every | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | QUERY: the query statement processed. This is an After variable and it returns a string.  
  To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
  For further information about variables, see Talend Studio User Guide. |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For related topics, see:

- Combining two flows for selective output on page 2529
- Procedure on page 635.
- Removing and regenerating a MySQL table index on page 2523.
tPostgresPlusSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

The tPostgresPlusSCD reflects and tracks changes in a dedicated MSSQL SCD table.

**tPostgresPlusSCD Standard properties**

These properties are used to configure tPostgresPlusSCD running in the Standard Job framework.

The Standard tPostgresPlusSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
<td></td>
</tr>
<tr>
<td>DB Version</td>
<td>List of database versions.</td>
</tr>
<tr>
<td>Server</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the DB schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2537. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. **Warning:** Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Additional JDBC Parameters

Specify additional JDBC parameters for the database connection being created.

This property is not available when the Use an existing connection check box in the Basic settings view is selected.

#### End date time details

Specify the time value of the SCD end date time setting in the format of **HH:mm:ss**. The default value for this field is **12:00:00**.

This field appears only when SCD Type 2 is used and **Fixed year value** is selected for creating the SCD end date.

#### Debug mode

Select this check box to display each step during processing entries in a database.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

#### Usage rule

This component is used as Output component. It requires an Input component and Row main link as input.

#### Dynamic settings

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access
PostgresPlusSCD database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation          | This component does not support using SCD type 0 together with other SCD types. |

**Related scenario**

For related topics, see tMysqlSCD on page 2534.
tPostgresPlusSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated PostgresPlus SCD table.

The tPostgresPlusSCDELT reflects and tracks changes in a dedicated Oracle SCD table.

**tPostgresPlusSCDELT Standard properties**

These properties are used to configure tPostgresPlusSCDELT running in the Standard Job framework.

The Standard tPostgresPlusSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally. Enter properties manually.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **Host** | The IP address of the database server. |
| **Port** | Listening port number of database server. |
| **Database** | Name of the database. |
| **Schema** | Exact name of the schema |
| **Username and Password** | User authentication data for a dedicated database. 
To enter the password, click the [... button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Source table** | Name of the input DB2 SCD table. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time |
| **Action on table** | Select to perform one of the following operations on the table defined: 
*None*: No action carried out on the table. 
*Drop and create table*: The table is removed and created again 
*Create table*: A new table gets created. 
*Create table if not exists*: A table gets created if it does not exist. 
*Clear table*: The table content is deleted. You have the possibility to rollback the operation. 
*Truncate table*: The table content is deleted. You don not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. 
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: 
*View schema*: choose this option to view the schema only. 
*Change to built-in property*: choose this option to change the schema to **Built-in** for local changes. 
*Update repository connection*: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in**: The schema is created and stored locally for this component only. | Related topic: see Talend Studio User Guide. |
Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Surrogate Key</th>
<th>Select the surrogate key column from the list.</th>
</tr>
</thead>
</table>
| Creation            | Select the method to be used for the surrogate key generation.  
                      | For more information regarding the creation methods, see SCD management methodology on page 2537. |
| Source Keys         | Select one or more columns to be used as keys, to ensure the unicity of incoming data. |
| Use SCD Type 1 fields | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.  |
| Use SCD Type 2 fields | Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.  |
| SCD type 2 fields   | Click the [+] button to add as many rows as needed, each row for a column. Click the arrow on the right side of the cell and select the column whose value changes will be tracked using Type 2 SCD from the drop-down list displayed.  
                      | This table is available only when the Use SCD type 2 fields option is selected. |
| Start date          | Specify the column that holds the start date for type 2 SCD.  
                      | This list is available only when the Use SCD type 2 fields option is selected. |
| End date            | Specify the column that holds the end date for type 2 SCD.  
                      | This list is available only when the Use SCD type 2 fields option is selected. |
| Log active status   | Select this check box and from the Active field drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD.  
                      | This option is available only when the Use SCD type 2 fields option is selected. |
| Log versions        | Select this check box and from the Version field drop-down list displayed, select the column that holds the version number of the record for type 2 SCD.  
                      | This option is available only when the Use SCD type 2 fields option is selected. |

Note: To avoid duplicated change records, it is recommended to select a column that can identify each change for this field.
### Advanced settings

Related Scenarios

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1874.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 3060.
**tPostgresqlBulkExec**

Improves performance while carrying out the Insert operations to a Postgresql database.

The tPostgresqlBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are used together to first output the file that will be then used as parameter to execute the SQL query stated. These two steps compose the tPostgresqlOutputBulkExec component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading in the database.

**tPostgresqlBulkExec Standard properties**

These properties are used to configure tPostgresqlBulkExec running in the Standard Job framework.

The Standard tPostgresqlBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>

**Advanced settings**

<table>
<thead>
<tr>
<th>Advanced settings</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection being created. This property is not available when the <strong>Use an existing connection</strong> check box in the Basic settings view is selected.</td>
</tr>
</tbody>
</table>
| **Action on data** | On the data of the table defined, you can perform:  
**Bulk Insert:** Add multiple entries to the table. If duplicates are found, job stops.  
**Bulk Update:** Make simultaneous changes to multiple entries. |
| **Copy the OID for each row** | Retrieve the ID item for each row. |
| **Contains a header line with the names of each column in the file** | Specify that the table contains header. |
| **File type** | Select the type of file being handled. |
| **Null string** | String displayed to indicate that the value is null. |
| **Fields terminated by** | Character, string or regular expression to separate fields. |
| **Escape char** | Character of the row to be escaped. |
| **Text enclosure** | Character used to enclose text. |
| **Activate standard_conforming_string** | Activate the variable. |
| **Force not null for columns** | Define the columns nullability.  
**Force not null:** Select the check box next to the column you want to define as not null. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with <strong>tPostgresqlOutPutBulk</strong> component. Used together, they can offer gains in performance while feeding a Postgresql database.</th>
</tr>
</thead>
</table>
| **Dynamic settings** | Click the `[+]` button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The **Dynamic settings** table is available only when the Use an existing connection check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](page 2472) and [Reading data from different MySQL databases using dynamically loaded connection parameters](page 495). For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

### Related scenarios

For use cases in relation with **tPostgresqlBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tPostgresqlClose

Closes the transaction committed in the connected Postgresql database.

**tPostgresqlClose Standard properties**

These properties are used to configure tPostgresqlClose running in the Standard Job framework.

The Standard tPostgresqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</tr>
</tbody>
</table>

Related scenarios

No scenario is available for the Standard version of this component yet.
tPostgresqlCommit

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresqlCommit validates the data processed through the Job into the connected DB

tPostgresqlCommit Standard properties

These properties are used to configure tPostgresqlCommit running in the Standard Job framework.

The Standard tPostgresqlCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

| Database | Select a type of database from the list and click Apply. |
| Component list | Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job. |
| Close Connection | This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. |

Warning:

If you want to use a Row > Main connection to link tPostgresqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tPostgresql* components, especially with the tPostgresqlConnection and tPostgresqlRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned |
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tPostgresqlCommit related scenario, see Inserting data in mother/daughter tables on page 2452.
tPostgresqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresqlConnection opens a connection to the database for a current transaction.

**tPostgresqlConnection Standard properties**

These properties are used to configure tPostgresqlConnection running in the Standard Job framework.

The Standard tPostgresqlConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong></td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of database versions.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
</tbody>
</table>
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not visible when the **Use or register a shared DB Connection** check box is selected.

**Data source alias**

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

**Advanced settings**

**Auto Commit**

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

**Usage**

**Usage rule**

This component is more commonly used with other **tPostgresql** components, especially with the **tPostgresqlCommit** and **tPostgresqlRollback** components.

**Related scenario**

For **tPostgresqlConnection** related scenario, see **tMysqlConnection** on page 2451
tPostgresqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

The tPostgresqlInput reads a database and extracts fields based on a query.

**tPostgresqlInput Standard properties**

These properties are used to configure tPostgresqlInput running in the Standard Job framework.

The Standard tPostgresqlInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.
### Table name
Name of the table to be read.

### Query type and Query
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Specify a data source alias
Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

This check box is not available when the Use an existing connection check box is selected.

### Data source alias
Enter the alias of the data source created on the Talend Runtime side.

This field is available only when the Specify a data source alias check box is selected.

### Advanced settings

- **Additional JDBC Parameters**
  Specify additional JDBC parameters for the database connection being created.
  
  This property is not available when the Use an existing connection check box in the Basic settings view is selected.

- **Use cursor**
  When selected, helps to decide the row set to work with at a time and thus optimize performance.

- **Trim all the String/Char columns**
  Select this check box to remove leading and trailing whitespace from all the String/Char columns.

- **Trim column**
  Remove leading and trailing whitespace from defined columns.

- **tStat Catcher Statistics**
  Select this check box to collect log data at the component level.

### Global Variables

- **Global Variables**
  - **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
  - **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
  - **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
  - A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
  - To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see *Talend Studio User Guide*.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Postgresql databases.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For related scenarios, see:

- Reading data from different MySQL databases using dynamically loaded connection parameters on page 495.
tPostgresqlOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

The tPostgresqlOutput writes, updates, makes changes or suppresses entries in a database.

**tPostgresqlOutput Standard properties**

These properties are used to configure tPostgresqlOutput running in the Standard Job framework.

The Standard tPostgresqlOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>

<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

<table>
<thead>
<tr>
<th>Table</th>
<th>Name of the table to be written. Note that only one table can be written at a time</th>
</tr>
</thead>
</table>

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if already exists and created again.
- **Clear table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You don not have the possibility to rollback the operation.

**Action on data**

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
### Update or insert
Update the record with the given reference. If the record does not exist, a new record would be inserted.

### Delete
Remove entries corresponding to the input flow.

**Warning:** It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation.

### Schema and Edit Schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Built-In
You create and store the schema locally for this component only. Related topic: see [Talend Studio User Guide](https://help.talend.com).

### Repository
You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see [Talend Studio User Guide](https://help.talend.com).

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Use spatial options
**Note:** This check box is available when you selected the table creation related option from the **Action on table list**.

Select this check box to use the PostgreSQL database as a spatial database for geographic information system (GIS).
When this check box is selected, two other check boxes are displayed:

- **Create Spatial index**: select this check box to create spatial index.
- **Create geometry columns reference**: select this check box to create geometry columns reference.

For more information about the PostgreSQL database, see http://www.postgresql.org/about/.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

This check box is not available when the Use an existing connection check box is selected.

### Data source alias

Enter the alias of the data source created on the Talend Runtime side.

This field is available only when the Specify a data source alias check box is selected.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Additional JDBC Parameters

Specify additional JDBC parameters for the database connection being created.

This property is not available when the Use an existing connection check box in the Basic settings view is selected.

#### Commit every

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

#### Additional Columns

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

**Name**: Type in the name of the schema column to be altered or inserted as new column

**SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position**: Select Before, Replace or After following the action to be performed on the reference column.

**Reference column**: Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.
| **Use save point** | Select this check box to use savepoints in the transaction. This check box will not be available if you select:  
  • the **Die on error** check box in the **Basic settings** view, or  
  • the **Use Batch Size** check box in the **Advanced settings** view.  
This check box will not work if you:  
  • type in 0 in the **Commit every** field, or  
  • select the **Use an existing connection** check box in the **Basic settings** view while the **Auto Commit** mode is activated in the database connection component. |
| **Use field options** | Select this check box to customize a request, especially when there is double action on data. |
| **Enable debug mode** | Select this check box to display each step during processing entries in a database. |
| **Support null in "SQL WHERE" statement** | Select this check box if you want to deal with the Null values contained in a DB table.  
**Note:** Ensure that the Nullable check box is selected for the corresponding columns in the schema. |
| **Use Batch** | Select this check box to activate the batch mode for data processing.  
**Note:** This check box is available only when you have selected the **Insert**, the **Update** or the **Delete** option in the **Action on data** field. |
| **Batch Size** | Specify the number of records to be processed in each batch.  
This field appears only when the **Use batch mode** check box is selected. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

| Global Variables |  
|------------------|---|
| **NB_LINE** | the number of rows processed. This is an After variable and it returns an integer. |
| **NB_LINE_UPDATED** | the number of rows updated. This is an After variable and it returns an integer. |
| **NB_LINE_INSERTED** | the number of rows inserted. This is an After variable and it returns an integer. |
| **NB_LINE_DELETED** | the number of rows deleted. This is an After variable and it returns an integer. |
| **NB_LINE_REJECTED** | the number of rows rejected. This is an After variable and it returns an integer. |
| **QUERY** | the query statement processed. This is an After variable and it returns a string. |
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Postgresql database. It also allows you to create a reject flow using a <strong>Row &gt; Rejects</strong> link to filter data in error. For an example of <strong>tMySqlOutput</strong> in use, see Retrieving data in error with a Reject link on page 2500.</th>
</tr>
</thead>
</table>

### Dynamic settings

Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <strong>Install</strong> button on the <strong>Component</strong> tab view. You can also find out and add all missing JARs easily on the <strong>Modules</strong> tab in the <strong>Integration</strong> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</th>
</tr>
</thead>
</table>
Related scenarios

For `tPostgresqlOutput` related topics, see:

- Inserting a column and altering data using `tMysqlOutput` on page 2492.
Prepares the file to be used as parameters in the INSERT query to feed the Postgresql database.

The tPostgresqlOutputBulk writes a file with columns based on the defined delimiter and the Postgresql standards.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component, detailed in a separate section. The advantage of having two separate steps is that it makes it possible to transform data before it is loaded in the database.

**tPostgresqlOutputBulk Standard properties**

These properties are used to configure tPostgresqlOutputBulk running in the Standard Job framework.

The Standard tPostgresqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>

</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is to be used along with tPostgresqlBulkExec component. Used together they offer gains in performance while feeding a Postgresql database. |

Related scenarios

For use cases in relation with tPostgresqlOutputBulk, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tPostgresqlOutputBulkExec

Improves performance during Insert operations to a Postgresql database.

The tPostgresqlOutputBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component.

**tPostgresqlOutputBulkExec Standard properties**

These properties are used to configure tPostgresqlOutputBulkExec running in the Standard Job framework.

The Standard tPostgresqlOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of database versions.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td></td>
<td>Currently, only localhost, 127.0.0.1 or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using tPostgresqlOutputBulkExec is deployed.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

**Table**

Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

**Action on table**

On the table defined, you can perform one of the following operations:
- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if already exists and created again.
- **Clear a table**: The table content is deleted.

**File Name**

Name of the file to be generated and loaded.

**Warning:**
This file is generated on the machine specified by the URI in the **Host** field and it should be on the same machine as the database server.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection being created.</td>
</tr>
</tbody>
</table>
| **Action on data** | On the data of the table defined, you can perform:  
- **Bulk Insert**: Add multiple entries to the table. If duplicates are found, job stops.  
- **Bulk Update**: Make simultaneous changes to multiple entries. |
| **Copy the OID for each row** | Retrieve the ID item for each row. |
| **Contains a header line with the names of each column in the file** | Specify that the table contains header. |
| **Use local file for copy (for DB server 8.2 or newer)** | Select this check box to copy files from the PostgreSQL client machine. |
| **Encoding** | Select the encoding from the list or select CUSTOM and define it manually. This field is compulsory for DB data handling. |
| **File type** | Select the type of file being handled. |
| **Null string** | String displayed to indicate that the value is null. |
| **Row separator** | String (ex: “\n” on Unix) to distinguish rows. |
| **Fields terminated by** | Character, string or regular expression to separate fields. |
| **Escape char** | Character of the row to be escaped. |
| **Text enclosure** | Character used to enclose text. |
| **Activate standard_conforming_string** | Activate the variable. |
| **Force not null for columns** | Define the columns nullability.  
- **Force not null**: Select the check box next to the column you want to define as not null. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Usage

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</td>
</tr>
<tr>
<td><strong>Limitation</strong></td>
<td>The database server must be installed on the same machine where the Studio is installed or where the Job is run.</td>
</tr>
</tbody>
</table>
using `tPostgresqlOutputBulkExec` is deployed, so that the component functions properly.

## Related scenarios

For use cases in relation with `tPostgresqlOutputBulkExec`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2508.
- Inserting data in bulk in MySQL database on page 2515.
- Truncating and inserting file data into an Oracle database on page 2716.
tPostgresqlRollback

Avoids to commit part of a transaction involuntarily.
The tPostgresqlRollback cancels the transaction commit in the connected DB.

**tPostgresqlRollback Standard properties**

These properties are used to configure tPostgresqlRollback running in the Standard Job framework.
The Standard tPostgresqlRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresql* components, especially with the tPostgresqlConnection and tPostgresqlCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection. |
Related scenario

For `tPostgresqlRollback` related scenario, see `tMysqlRollback` on page 2517.
tPostgresqlRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresqlRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output.

**tPostgresqlRow Standard properties**

These properties are used to configure tPostgresqlRow running in the Standard Job framework.

The Standard tPostgresqlRow component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **DB Version** | List of database versions. |
| **Host** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database. |
| **Schema** | Name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-In**: | You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository**: | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*. |
| **Query type** | Either **Built-in** or **Repository**. |
| **Built-in**: | Fill in manually the query statement or build it graphically using SQLBuilder |
| **Repository**: | Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
| **Specify a data source alias** | Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. |
This option works only when you deploy and run your Job in *Talend Runtime*. This check box is not available when the **Use an existing connection** check box is selected.

<table>
<thead>
<tr>
<th>Data source alias</th>
<th>Enter the alias of the data source created on the <em>Talend Runtime</em> side. This field is available only when the <strong>Specify a data source alias</strong> check box is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a <strong>Row &gt; Rejects</strong> link.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Specify additional JDBC parameters for the database connection being created. This property is not available when the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong> view is selected.</th>
</tr>
</thead>
</table>
| **Propagate QUERY's recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.  
  
  **Note:**  
  This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY's recordset should be set to the type of Object and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by '?' in the SQL instruction of the **Query** field in the **Basic Settings** tab.  
  
  **Parameter Index:** Enter the parameter position in the SQL instruction.  
  
  **Parameter Type:** Enter the parameter type.  
  
  **Parameter Value:** Enter the parameter value.  
  
  **Note:** This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

---

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

---

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-in**          | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**        | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **SCD Editor**        | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see SCD management methodology on page 2537. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. |

**Warning:**

Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.
### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**Additional JDBC Parameters**

Specify additional JDBC parameters for the database connection being created.

This property is not available when the Use an existing connection check box in the Basic settings view is selected.

**End date time details**

Specify the time value of the SCD end date time setting in the format of `HH:mm:ss`. The default value for this field is `12:00:00`.

This field appears only when SCD Type 2 is used and **Fixed year value** is selected for creating the SCD end date.

**Debug mode**

Select this check box to display each step during processing entries in a database.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.
- **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.
- **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**

This component is used as Output component. It requires an Input component and Row main link as input.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces...
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation                      | This component does not support using SCD type 0 together with other SCD types. |

**Related scenario**

For related topics, see **tMysqlSCD** on page 2534.
**tPostgresqlSCDELT**

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated DB2 SCD table.

The tPostgresqlSCDELT reflects and tracks changes in a dedicated Postgresql SCD table.

**tPostgresqlSCDELT Standard properties**

These properties are used to configure tPostgresqlSCDELT running in the Standard Job framework.

The Standard tPostgresqlSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</thead>
</table>
| **Creation**      | Select the method to be used for the surrogate key generation.  
For more information regarding the creation methods, see SCD management methodology on page 2537. |
| **Source Keys**   | Select one or more columns to be used as keys, to ensure the unicity of incoming data. |
| **Use SCD Type 1 fields** | Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes. |
| **Use SCD Type 2 fields** | Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes. |
| **SCD type 2 fields** | Click the [+] button to add as many rows as needed, each row for a column. Click the arrow on the right side of the cell and select the column whose value changes will be tracked using Type 2 SCD from the drop-down list displayed.  
This table is available only when the **Use SCD type 2 fields** option is selected. |
| **Start date**    | Specify the column that holds the start date for type 2 SCD.  
This list is available only when the **Use SCD type 2 fields** option is selected. |
| **End date**      | Specify the column that holds the end date for type 2 SCD.  
This list is available only when the **Use SCD type 2 fields** option is selected. |
| **Log active status** | Select this check box and from the Active field drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD.  
This option is available only when the **Use SCD type 2 fields** option is selected. |
| **Log versions**  | Select this check box and from the Version field drop-down list displayed, select the column that holds the version number of the record for type 2 SCD.  
This option is available only when the **Use SCD type 2 fields** option is selected. |

**Advanced settings**

| **Additional JDBC Parameters** | Specify additional JDBC parameters for the database connection being created. |

**Note:** To avoid duplicated change records, it is recommended to select a column that can identify each change for this field.
| **Debug mode** | Select this check box to display each step during processing entries in a database. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

## Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

## Usage

**Usage rule**

This component is used as an output component. It requires an input component and Row main link as input.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2472 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 495. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).
Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component

This scenario describes a Job that captures the employee data changes in a PostgreSQL table using SCD (Slowly Changing Dimensions) Type 1 and Type 2 methods implemented by the tPostgreSQLSCDELT component, and writes both the current and historical data in a SCD dimension table.

The input data contains various employee details including name, role, salary, and another id column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new Snowflake table.

<table>
<thead>
<tr>
<th>#id; name; role; salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1; Mark Smith; tester; 11000.00</td>
</tr>
<tr>
<td>2; Thomas Johnson; developer; 12000.00</td>
</tr>
<tr>
<td>3; Teddy Brown; tester; 13000.00</td>
</tr>
</tbody>
</table>

Later, the table is updated with the following renewed employee data.

<table>
<thead>
<tr>
<th>#id; name; role; salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1; Mark Smith; tester; 15000.00</td>
</tr>
<tr>
<td>2; Thomas Johnson; tester; 18000.00</td>
</tr>
<tr>
<td>3; Teddy Brown; writer; 17000.00</td>
</tr>
<tr>
<td>4; John Clinton; developer; 19000.00</td>
</tr>
</tbody>
</table>

You can see the role of Thomas Johnson is changed from developer to tester, the role of Teddy Brown is changed from tester to writer, and his salary is raised from 13000.00 to 17000.00. Besides, a new employee record with id 4 is inserted. In this scenario,

- the existing name and role data will be overwritten by the new data, so SCD Type 1 method will be performed on them, and
- the full history of the salary data will be retained, and a new record with the changed data will be always created and the previous record will be closed, so SCD Type 2 method will be performed on it.

For more information about SCD types, see SCD management methodology on page 2537.

Creating a Job for tracking data changes in a PostgreSQL table using tPostgresqlSCDELT

Procedure

1. Create a new Job and add a tPostgreSQLConnection component, a tCreateTable component, two tFixedFlowInput components, two tPostgreSQL Input components, two tPostgreSQLOutput components, two tPostgreSQLSCDELT components, and two tLogRow components to the Job.
2. Link the first tFixedFlowInput component to the first tPostgreSQLOutput component using a Row > Main connection.

3. Do the same to link the first tPostgreSQLInput component to the first tLogRow component, the second tFixedFlowInput component to the second tPostgreSQLOutput component, and the second tPostgreSQLInput component to the second tLogRow component.

4. Link the tPostgreSQLConnection component to the tCreateTable component using a Trigger > On Subjob Ok connection.

5. Do the same to link the first tFixedFlowInput component to the first tPostgreSQLSCDELT component, the first tPostgreSQLSCDELT component to the first tPostgreSQLInput component, the first tPostgreSQLInput component to the second tFixedFlowInput component, the second tFixedFlowInput component to the second tPostgreSQLSCDELT component, the second tPostgreSQLSCDELT component to the second tPostgreSQLInput component, and the second tPostgreSQLInput component to the second tPostgreSQLSCDELT component.

Opening a connection to a PostgreSQL database
Procedure

1. Double-click the **tPostgreSQLConnection** component to open its **Basic settings** view.

![Basic settings view of tPostgreSQLConnection](image1.png)

2. In the **Host**, **Port**, **Database**, **Schema**, **Username**, and **Password** fields, enter the information required for the connection to the PostgreSQL database.

Creating a PostgreSQL table

Procedure

1. Double-click the **tCreateTable** component to open its **Basic settings** view.

![Basic settings view of tCreateTable](image2.png)

2. In the **Basic settings** view, and from the **Database Type** list, select Postgresql for this scenario.

3. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, **tPostgreSQLConnection_1** in this example.

4. In the **Table Name** field, fill in a name for the table to be created, **employee** in this example.

5. From the **Table Action** list, select **Create table if not exist**.

6. Click the [...] button next to **Edit schema** and in the pop-up dialog box, define the schema by adding four columns: **id** of Integer type as the primary key, **name** and **role** of String type, and **salary** of Double type.

   In the end, a new table **employee** is created to store the employee data.
Inserting data into the new PostgreSQL table

Procedure

1. Double-click the first `tFixedFlowInput` component to open its Basic settings view.
2. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding four columns: id of Integer type as the primary key, name and role of String type, and salary of Double type.
3. Click OK to save the schema changes. In the pop-up dialog box, click Yes to propagate the schema to the next component.
4. Select Use Inline Content in the Mode area. Then in the Content field displayed, enter the following employee data to be inserted.

```
1;Mark Smith;tester;11000.00
2;Thomas Johnson;developer;12000.00
3;Teddy Brown;tester;13000.00
```

5. Double-click the first tPostgreSQLOutput component to open its Basic settings view.

6. Select the Use an existing connection check box and from the Component List drop-down list displayed, and then select the connection component to reuse the connection created by it, tPostgreSQLConnection_1 in this example.

7. In the Table field, enter the name of the table into which the employee data will be written, employee in this example.

8. In the Action on table drop-down list, select Default.

9. In the Action on data drop-down list, select Insert to insert the employee data transferred from the first tFixedFlowInput component.

10. Click the [...] button next to Edit schema to check whether the schema of tPostgreSQLOutput is the same as the schema of tFixedFlowInput.

---

**Tracking inserted data changes and writing the changes into a SCD dimension table**

**Procedure**

1. Double-click the first tPostgreSQLSCDELT component to open its Basic settings view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

3. In the **Source table** field, enter the name of the table whose data changes will be captured, `employee` in this example.

4. In the **Table** field, enter the name of the SCD dimension table that will store both the current and historical employee data, `employee_scd` in this example.

5. Select **Create table** from the **Action on table** drop-down list to create the SCD dimension table.

6. Click the [...] button next to **Edit schema** and in the pop-up dialog box, define the schema by adding nine columns: `sk` (as the primary key) and `id` of Integer type, `name` and `role` of String type, `salary` of Double type, `start_date` and `end_date` of Date type with the Date Pattern `dd-MM-yyyy`, and `active_status` and `version` of Integer type. When done, click **OK** to save the changes and close the dialog box.
7. From the **Surrogate key** drop-down list, select the name of the column that will be used as the primary key of the SCD dimension table, `sk` in this example.

8. Select `DB sequence` from the **Creation** drop-down list and in the **Sequence** field displayed, enter the name of the PostgreSQL sequence used to generate the surrogate key for the SCD Type 2 method, `employee_sequence` in this example.

9. Click the `[+]` button below the **Source keys** table to add a new line, and click the **Name** cell and select the key column of the source table from the drop-down list, `id` in this example.

10. Select the **Use SCD type 1 fields** check box, click the `[+]` button below the **SCD type 1 fields** table twice to add two lines. Then click each cell and from the drop-down list, select the column on which the SCD Type 1 method will be performed. In this example, they are `name` and `role`.

11. Select the **Use SCD type 2 fields** check box, click the `[+]` button below the **SCD type 2 fields** table to add a line. Then click the cell and select the column on which the SCD Type 2 method will be performed. In this example, it is `salary`.

12. From the **Start date** and **End date** drop-down lists, select the columns used to hold the start date and end date values for the SCD Type 2 method respectively, `start_date` and `end_date` in this example.

13. Select the **Log active status** check box and from the **Active field** drop-down list displayed, select the column used to hold the active status value for the SCD Type 2 method, which helps identify the active records, `active_status` in this example.

14. Select the **Log versions** check box and from the **Version field** drop-down list, select the column used to hold the version number of the records for the SCD Type 2 method, `version` in this example.

**Retrieving the data updates from the SCD dimension table**

**Procedure**

1. Double-click the first `tPostgreSQLInput` component to open its **Basic settings** view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

3. Click the `[...]` button next to **Edit schema** and in the pop-up dialog box, define the schema by adding nine columns: `sk` and `id` of Integer type as the primary key, `name` and `role` of String type, `salary` of Double type, `start_date` and `end_date` of Date type with the Date Pattern `yyyy-MM-dd`, and `active_status` and `version` of Integer type. When done, click **OK** to save the changes and close the dialog box.

   The schema of the first `tPostgreSQLInput` component is the same as the schema of the `tPostgreSQLSCDELT1` component, you can just copy and paste it.

4. In the **Query** field, enter the SQL command used to retrieve data from the SCD dimension table, `select * from employee_scd` in this example.

5. In the **Table Name** field, enter the name of the SCD dimension table where you will retrieve the data updates, `employee_scd` in this example.

6. Double-click the first `tLogRow` component and in the **Mode** area on its **Basic settings** view, select **Table** to display the retrieved data in a table.

**Updating data in the Postgresql table**

**Procedure**

1. Double-click the second `tFixedFlowInput` component to open its **Basic settings** view.

2. Click the `[...]` button next to **Edit schema** and in the pop-up dialog box, define the schema by adding four columns: `id` of Integer type as the primary key, `name` and `role` of String type, and `salary` of Double type.

   This schema is the same as the schema of the first `tFixedFlowInput` component, you can just copy and paste it.

3. Click **OK** to save the schema changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

4. Select **Use Inline Content** in the **Mode** area. Then in the **Content** field displayed, enter the following employee data to update the existing data.

   ```
   1;Mark Smith;tester;15000.00
   2;Thomas Johnson;tester;18000.00
   3;Teddy Brown;writer;17000.00
   4;John Clinton;developer;19000.00
   ```

5. Double-click the second `tPostgreSQLOutput` component to open its **Basic settings** view.

6. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

7. In the **Table** field, enter the name of the table, in which the data will be updated, `employee` in this example.

8. Select **Default** from the **Action on table** drop-down list.

9. Select **Insert or update** from the **Action on data** drop-down list.

**Tracking data update changes and writing the changes into the SCD dimension table**
Procedure
1. Double-click the second tPostgreSQLSCDELT component to open its Basic settings view.
2. Repeat 2 on page 3065 through 14 on page 3066 in the procedure Tracking inserted data changes and writing the changes into a SCD dimension table on page 3064 to configure the second tPostgreSQLSCDELT component.

Retrieve the data update changes from the SCD dimension table

Procedure
1. Double-click the second tPostgreSQLInput component to open its Basic settings view.
2. Repeat 2 on page 3067 through 5 on page 3067 in the procedure Retrieving the data updates from the SCD dimension table on page 3066 to configure the second tPostgreSQLInput component.
3. Double-click the second tLogRow component and in the Mode area on its Basic settings view, select Table to display the retrieved data in a table.

Executing the Job to track data changes in a PostgreSQL table using tPostgreSQLSCDELT

Procedure
1. Press Ctrl + S to save the Job.
2. Press F6 to execute the Job.

As shown above, the old role developer for Thomas Johnson is overwritten directly by the new role tester because SCD Type 1 is performed on the role column, and a new record with the surrogate key value set to 26 is created for Teddy Brown’s salary update from 13000.00 to 17000.00 because SCD Type 2 is performed on the salary column.
Related Scenario

For related topics, see tMysqlSCD on page 2534 and Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1874.
**tPostjob**

Triggers a task required after the execution of a Job
tPostjob starts the execution of a postjob.

**tPostjob Standard properties**

These properties are used to configure tPostjob running in the Standard Job framework.
The Standard tPostjob component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

**Global Variables**

**Handling files before and after the execution of a data Job**

In this scenario, a pre-job and a post-job are added to the Job describes in Finding duplicate files between two folders on page 1108 to handle files before and after the execution of the main data Job.
As described in the above-mentioned scenario, when the main data Job is started, it creates a temporary text file to store the fetched filenames. If the specified temporary file already exists, it will be overwritten.

To prevent possible loss of data, the pre-job saves a backup copy of the specified file by renaming it, if it exists, before the main Job is executed.

After the execution of the main data Job, the post-job deletes the temporary file created by the data Job and restores the backup file, if any.

---

### Adding and linking components

**Procedure**

1. With the main Job open on the design workspace, add a `tPrejob`, a `tPostjob`, a `tFileDelete`, and two `tFileCopy` components to the Job.
2. Link the `tPrejob` component to the first `tFileCopy` component using a `Trigger > On Component Ok` connection to build the pre-job.
3. Link the `tPostjob` component the `tFileDelete` component using a `Trigger > On Component Ok` connection, and link the `tFileDelete` component to the other `tFileCopy` component to build the post-job.
4. Label the relevant components to better identify their roles.

### Configuring the components

**Configuring the pre-job**

**About this task**

In the pre-job, the `tPrejob` component does not have any parameter or property to configure; it just triggers the `tFileCopy` component before the execution of the main data Job to rename the specified file, so all the required configurations are made in the `tFileCopy` component.

**Procedure**

1. Double-click the `tFileCopy` component to show its Basic settings view.
2. Fill the **File Name** field with the path and filename of the temporary text file to be renamed, *D:/temp/tempdata.csv* in this example.

3. In the **Destination directory** field, specify or browse to destination directory. In this example, we will save the backup copy in the same directory, *D:/temp/*

4. Select the **Rename** check box, and specify the new filename in the **Destination filename** field, *backup-tempdata.csv*. Leave the other parameters as they are.

**Configuring the post-job**

**About this task**

In the post-job, the **tPostjob** component does not have any parameter or property to configure; it just triggers the **tFileDelete** component after the execution of the main data Job to delete the temporary file used to store the fetched filenames, which then triggers the **tFileCopy** component to name the backup file back to its original name.

**Procedure**

1. In the **Basic settings** view of the **tFileDelete** component, fill the **File Name** field with the path and filename of the temporary file to be deleted, *D:/temp/tempdata.csv* in this example, and leave the other parameters as they are.

2. Double-click the **tFileCopy** component to open its **Basic settings** view.
3. Fill the **File Name** field with the path and filename of the backup file, *D:/temp/backup-tempdata.csv* in this example.

4. In the **Destination directory** field, specify or browse to destination directory, *D:/temp/* in this example.

5. Select the **Rename** check box, and specify the original name of the temporary file in the **Destination filename** field, *tempdata.csv*.

6. Select the **Remove source file** check box to remove the backup file after the renaming action. Leave the other parameters as they are.

**Expected execution result**

If the specified temporary file exists, its data will be saved in a backup copy before the main data Job is executed and restored thereafter.

If the temporary file does not exist, the two **tFileCopy** components will generate an error, but this does not prevent the main data Job from being executed.

For the execution result of the main data Job, see *Finding duplicate files between two folders* on page 1108.

**Related scenario**

For another scenario that uses the **tPrejob** component, see *Creating a bar chart from the input data* on page 345.
tPubSubOutput

Receives messages serialized into byte arrays by its preceding component and issues these messages into a given PubSub service.
tRedshiftBulkExec

Loads data into Amazon Redshift from Amazon S3, Amazon EMR cluster, Amazon DynamoDB, or remote hosts.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

tRedshiftBulkExec loads data into an Amazon Redshift table from an Amazon DynamoDB table or from data files located in an Amazon S3 bucket, an Amazon EMR cluster, or a remote host that is accessed using an SSH connection.

**tRedshiftBulkExec Standard properties**

These properties are used to configure tRedshiftBulkExec running in the Standard Job framework.

The Standard tRedshiftBulkExec component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property Type</strong></td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: Select the repository file where the properties are stored.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Type in the name of the database.</td>
</tr>
<tr>

<td>Type in the name of the schema.</td>
</tr>
<tr>
<td><strong>Username</strong> and <strong>Password</strong></td>
<td>Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

### Additional JDBC Parameters
Specify additional JDBC properties for the connection you are creating. The properties are separated by `ampersand &` and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL.

### Table Name
Specify the name of the table to be written. Note that only one table can be written at a time.

### Action on table
On the table defined, you can perform one of the following operations:
- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.
- **Built-In**: You create and store the schema locally for this component only. Related topic: see _Talend Studio User Guide_.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see _Talend Studio User Guide_.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Data source type
Select the location of the source data to be loaded.
- **S3**: load data from a file in an Amazon S3 bucket.
- **EMR**: load data from an Amazon EMR cluster.
- **DynamoDB**: load data from an existing DynamoDB table.
<table>
<thead>
<tr>
<th>Section</th>
<th>Description</th>

<tr>
<td><strong>Assume Role</strong></td>
<td>Select this check box and specify the values for the following parameters used to create a new assumed role session. - <strong>IAM Role ARNs chains</strong>: a series of chained roles, which may belong to other accounts, that your cluster can assume to access resources. You can chain a maximum of 10 roles. - <strong>Role ARN</strong>: the Amazon Resource Name (ARN) of the role to assume. For more information on IAM Role ARNs chains, see Authorizing Redshift service.</td>
</tr>
<tr>
<td><strong>Bucket</strong></td>
<td>Specify the name of the Amazon S3 bucket in which the file is located. This field is available only when S3 or Remote host is selected from the Data source type drop-down list. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.</td>
</tr>
<tr>
<td><strong>Key</strong></td>
<td>Specify the object key for the file that contains the data to be loaded. This field is available only when S3 is selected from the Data source type drop-down list.</td>
</tr>
<tr>
<td><strong>Cluster id</strong></td>
<td>Specify the ID of the cluster that stores the data to be loaded. This field is available only when EMR is selected from the Data source type drop-down list.</td>
</tr>
<tr>
<td><strong>HDFS path</strong></td>
<td>Specify the HDFS file path that references the data file. This field is available only when EMR is selected from the Data source type drop-down list.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Specify the name of the DynamoDB table that contains the data to be loaded. This field is available only when DynamoDB is selected from the Data source type drop-down list.</td>
</tr>
</tbody>
</table>
| **Read ratio** | Specify the percentage of the DynamoDB table’s provisioned throughput to use for the data load.  
This field is available only when **DynamoDB** is selected from the **Data source type** drop-down list. |
| **SSH manifest file** | Specify the object key for the SSH manifest file that provides the information used to open SSH connections and execute remote commands.  
This field is available only when **Remote host** is selected from the **Data source type** drop-down list. |

**Advanced settings**

| **File type** | Select the type of the file that contains the data to be loaded.  
- **Delimited file or CSV**: a delimited/CSV file.  
- **JSON**: a JSON file.  
- **AVRO**: an Avro file.  
- **Fixed width**: a fixed-width file.  
This list is available when **S3**, **EMR**, or **Remote host** is selected from the **Data source type** drop-down list. |
| **Fields terminated by** | Enter the character used to separate fields.  
This field is available only when **Delimited file or CSV** is selected from the **File type** list. |
| **Enclosed by** | Select the character in which the fields are enclosed.  
This list is available only when **Delimited file or CSV** is selected from the **File type** list. |
| **JSON mapping** | Specify how to map the data elements in the source file to the columns in the target table on Amazon Redshift. The valid values are:  
- **auto**: Map the data by matching object keys or names in the source name/value pairs for a JSON file or field names in the Avro schema for an Avro file to the names of columns in the target table. The argument is case-sensitive and must be enclosed in double quotation marks.  
- **s3://jsonpaths_file**: Map the data using the named JSONPaths file. The parameter must be an Amazon S3 object key that is enclosed in double quotation marks and explicitly references a single file, for example, **s3://mybucket/jsonpaths.txt**. For more information, see Data Format Parameters.  
This field is available only when **JSON** or **AVRO** is selected from the **File type** list. |
| **Fixed width mapping** | Enter a string that specifies a user-defined column label and column width between double quotation marks. The format of the string is:  
**ColumnLabel1:ColumnWidth1,ColumnLabel2:ColumnWidth2,**...  
Note that the column label in the string has no relation to the table column name and it can be either a text string or

</tr>
<tr>
<td></td>
<td>• <strong>Value</strong>: Set the value for the corresponding parameter. Note that you cannot set the value for a parameter (such as IGNOREBLANKLINES) that does not need a value.</td>
</tr>
</tbody>
</table>
For more information about the parameters, see http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html.

### JDBC url

Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.
- **Standard**: Use the standard way to access the Redshift database.
- **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This property is available only when Use an existing connection check box is not selected from the Basic settings. Once enabled, the Username and Password properties in Basic settings will be hidden, and then you should go to Additional JDBC Parameters to specify parameters for access.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

**Usage rule**

The tRedshiftBulkExec component supports loading data to Amazon Redshift from a delimited/CSV, JSON, or fixed-width file on Amazon S3, but the tRedshiftOutputBulk component now only supports generating and uploading a delimited/CSV file to Amazon S3. When you need to load data from a JSON or fixed-width file, you can use the tFileOutputJSON or tFileOutputPositional component together with the tS3Put component instead of using the tRedshiftOutputBulk component to generate and upload the file to Amazon S3.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for
example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Loading/unloading data from/to Amazon S3

This scenario describes a Job that generates a delimited file and uploads the file to S3, loads data from the file on S3 to Redshift and displays the data on the console, then unloads the data from Redshift to files on S3 per slice of the Redshift cluster, and finally lists and gets the unloaded files on S3.
Prerequisites:
The following context variables have been created and saved in the Repository tree view. For more information about context variables, see Talend Studio User Guide.

- **redshift_host**: the connection endpoint URL of the Redshift cluster.
- **redshift_port**: the listening port number of the database server.
- **redshift_database**: the name of the database.
- **redshift_username**: the username for the database authentication.
- **redshift_password**: the password for the database authentication.
- **redshift_schema**: the name of the schema.
- **s3_accesskey**: the access key for accessing Amazon S3.
- **s3_secretkey**: the secret key for accessing Amazon S3.
- **s3_bucket**: the name of the Amazon S3 bucket.
Adding and linking components

Procedure

1. Create a new Job and apply all context variables listed above to the new Job.
2. Add the following components by typing their names in the design workspace or dropping them from the Palette: a tRowGenerator component, a tRedshiftOutputBulk component, a tRedshiftBulkExec component, a tRedshiftInput component, a tLogRow component, a tRedshiftUnload component, a tS3List component, and a tS3Get component.
3. Link tRowGenerator to tRedshiftOutputBulk using a Row > Main connection.
4. Do the same to link tRedshiftInput to tLogRow.
5. Link tS3List to tS3Get using a Row > Iterate connection.
6. Link tRowGenerator to tRedshiftBulkExec using a Trigger > On Subjob Ok connection.
7. Do the same to link tRedshiftBulkExec to tRedshiftInput, link tRedshiftInput to tRedshiftUnload, link tRedshiftUnload to tS3List.

Configuring the components

Preparing a file and uploading the file to S3

Procedure

1. Double-click tRowGenerator to open its RowGenerator Editor.
2. Click the [+] button to add two columns: ID of Integer type and Name of String type.

3. Click the cell in the Functions column and select a function from the list for each column. In this example, select Numeric.sequence to generate sequence numbers for the ID column and select TalendDataGenerator.getFirstName to generate random first names for the Name column.

4. In the Number of Rows for RowGenerator field, enter the number of data rows to generate. In this example, it is 20.

5. Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

6. Double-click tRedshiftOutputBulk to open its Basic settings view on the Component tab.

7. In the Data file path at local field, specify the local path for the file to be generated. In this example, it is E:/Redshift/redshift_bulk.txt.

8. In the Access Key field, press Ctrl + Space and from the list select context.s3_accesskey to fill in this field.

   Do the same to fill the Secret Key field with context.s3_accesskey and the Bucket field with context.s3_bucket.

9. In the Key field, enter a new name for the file to be generated after being uploaded on Amazon S3. In this example, it is person_load.
Loading data from the file on S3 to Redshift

Procedure

1. Double-click tRedshiftBulkExec to open its Basic settings view on the Component tab.

   ![tRedshiftBulkExec](image.png)

   - **Basic settings**
     - **Host**: context.redshift_host
     - **Port**: context.redshift_port
     - **Database**: context.redshift_database
     - **Username**: context.redshift_username
     - **Password**: context.redshift_password
     - **Access Key**: context.s3_accesskey
     - **Secret Key**: context.s3_secretkey
     - **Bucket**: context.s3_bucket
     - **Table Name**: "person"

2. In the Host field, press **Ctrl + Space** and from the list select context.redshift_host to fill in this field. Do the same to fill:
   - the Port field with context.redshift_port,
   - the Database field with context.redshift_database,
   - the Schema field with context.redshift_schema,
   - the Username field with context.redshift_username,
   - the Password field with context.redshift_password,
   - the Access Key field with context.s3_accesskey,
   - the Secret Key field with context.s3_secretkey, and
   - the Bucket field with context.s3_bucket.

3. In the Table Name field, enter the name of the table to be written. In this example, it is *person*.

4. From the Action on table list, select **Drop table if exists and create**.

5. In the Key field, enter the name of the file on Amazon S3 to be loaded. In this example, it is *person_load*.

6. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: **ID** of Integer type and **Name** of String type.
Retrieving data from the table on Redshift

Procedure

1. Double-click tRedshiftInput to open its Basic settings view on the Component tab.

   ![tRedshiftInput_1](image)

   2. Fill the Host, Port, Database, Schema, Username, and Password fields with their corresponding context variables.

   3. In the Table Name field, enter the name of the table to be read. In this example, it is `person`.

   4. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: `ID` of Integer type and `Name` of String type.

   5. In the Query field, enter the following SQL statement based on which the data are retrieved.

   ```sql
   "SELECT * FROM" + context.redshift_schema + "person ORDER BY \"ID\"
   ```

   6. Double-click tLogRow to open its Basic settings view on the Component tab.
In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the result.

### Unloading data from Redshift to file(s) on S3

#### Procedure

1. Double-click **tRedshiftUnload** to open its **Basic settings** view on the **Component** tab.

![tRedshiftUnload_1](image)

2. Fill the **Host**, **Port**, **Database**, **Schema**, **Username**, and **Password** fields with their corresponding context variables.

   Fill the **Access Key**, **Secret Key**, and **Bucket** fields also with their corresponding context variables.

3. In the **Table Name** field, enter the name of the table from which the data will be read. In this example, it is `person`.

4. Click the [...] button next to **Edit schema** and in the pop-up window define the schema by adding two columns: **ID** of Integer type and **Name** of String type.

5. In the **Query** field, enter the following SQL statement based on which the result will be unloaded.

   ```sql
   "SELECT * FROM person"
   ```

6. In the **Key prefix** field, enter the name prefix for the unload files. In this example, it is `person_unload_`.

Retrieving files unloaded to Amazon S3

Procedure

1. Double-click tS3List to open its Basic settings view on the Component tab.

2. Fill the Access Key and Secret Key fields with their corresponding context variables.

3. From the Region list, select the AWS region where the unload files are created. In this example, it is US Standard.

4. Clear the List all buckets objects check box, and click the [+ ] button under the table displayed to add one row.

   Fill in the Bucket name column with the name of the bucket in which the unload files are created. In this example, it is the context variable context.s3_bucket.

   Fill in the Key prefix column with the name prefix for the unload files. In this example, it is person_unload_.

5. Double-click tS3Get to open its Basic settings view on the Component tab.

6. Fill the Access Key field and Secret Key field with their corresponding context variables.

7. From the Region list, select the AWS region where the unload files are created. In this example, it is US Standard.
8. In the **Bucket** field, enter the name of the bucket in which the unload files are created. In this example, it is the context variable `context.s3_bucket`.

   In the **Key** field, enter the name of the unload files by pressing **Ctrl + Space** and from the list selecting the global variable `((String)globalMap.get("tS3List_1_CURRENT_KEY"))`.

9. In the **File** field, enter the local path where the unload files are saved. In this example, it is `"E:/Redshift/ + ((String)globalMap.get("tS3List_1_CURRENT_KEY"))`.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

   ```
   [statistics] connecting to socket on port 3726
   [statistics] connected
   LogRow_1
   ID|Name
   1|Abraham
   2|Herbert
   3|Chester
   4|John
   5|Gerald
   6|Lyndon
   7|Warren
   8|Calvin
   9|Chester
   10|Herbert
   11|Ronald
   12|Herbert
   13|Martin
   14|James
   15|Franklin
   16|Herbert
   17|Richard
   18|Warren
   19|Jimmy
   20|George
   [statistics] disconnected
   ```

![Image of AWS S3 bucket with uploaded files]
As shown above, the generated data is written into the local file `redshift_bulk.txt`, the file is uploaded on S3 with the new name `person_load`, and then the data is loaded from the file on S3 to the table `person` in Redshift and displayed on the console. After that, the data is unloaded from the table `person` in Redshift to two files `person_unload_0000_part_00` and `person_unload_0001_part_00` on S3 per slice of the Redshift cluster, and finally the unloaded files on S3 are listed and retrieved in the local folder.
**tRedshiftClose**

Closes the transaction committed in the connected DB.

This component is used together with tRedShiftConnection and tRedshiftCommit to ensure the integrity of the transaction performed into the database.

**tRedshiftClose Standard properties**

These properties are used to configure tRedshiftClose running in the Standard Job framework.

The Standard tRedshiftClose component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>

<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Amazon Redshift components, especially with tRedshiftConnection and tRedshiftCommit.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic
Related scenario

For a related scenario, see Handling data with Redshift on page 3103.
tRedshiftCommit

Provides gain in performance.

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch.

tRedshiftCommit validates the data processed through the Job into the connected database.

**tRedshiftCommit Standard properties**

These properties are used to configure tRedshiftCommit running in the Standard Job framework.

The Standard tRedshiftCommit component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tRedshiftConnection</strong> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

If you want to use a Row > Main connection to link tRedshiftCommit to your Job, your data will be committed row by row. In this case, do not select the **Close Connection** check box or your connection will be closed before the end of your first row commit.

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the **tRedshiftConnection** and **tRedshiftRollback** components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database |
RedshiftCommit connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For a similar scenario, see Inserting data in mother/daughter tables on page 2452.
tRedshiftConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The Standard tRedshiftConnection component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

**tRedshiftConnection Standard properties**

These properties are used to configure tRedshiftConnection running in the Standard Job framework.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Host name or IP address of DB server.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; ssifactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
</tbody>
</table>
### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

### Advanced settings

#### Log file

Specify the path to the log file to be generated during the data retrieval process.

Note that if the logging information needs to be saved and this component reuses the connection created by a **tRedshiftConnection** component, you must specify the property `loglevel=1/2/3` in the **Additional JDBC Parameters** field of the **tRedshiftConnection** component.

There is no limitation on the size of the log file. If the specified log file already exists, it will be overwritten.

#### Logging level

Select a logging level from the drop-down list to specify which kind of events will be logged in the log file.

#### Auto Commit

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding **commit** component to commit changes to the database; likewise, when using the corresponding **commit** component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding **commit** component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### JDBC url

Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.

- **Standard**: Use the standard way to access the Redshift database.
- **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.
This property is available only when **Use an existing connection** check box is not selected from the **Basic settings**. Once enabled, the **Username** and **Password** properties in **Basic settings** will be hidden, and then you should go to **Additional JDBC Parameters** to specify parameters for access.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the **tRedshiftCommit** and **tRedshiftRollback** components. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

**Related scenario**

For a related scenario, see **Handling data with Redshift** on page 3103.
tRedshiftInput

Reads data from a database and extracts fields based on a query so that you may apply changes to the extracted data.

tRedshiftInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component through a Main row link.

**tRedshiftInput Standard properties**

These properties are used to configure tRedshiftInput running in the Standard Job framework.

The Standard tRedshiftInput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](#).

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Hostname or IP address of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Name of the table from which the data will be read.</th>

<td>Click the <strong>Guess Query</strong> button to generate the query which corresponds to your table schema in the <strong>Query</strong> field.</td>
</tr>
<tr>
<td><strong>Guess schema</strong></td>
<td>Click the <strong>Guess schema</strong> button to retrieve the table schema.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **Log file** | Specify the path to the log file to be generated during the data retrieval process. Note that if the logging information needs to be saved and this component reuses the connection created by a **tRedshiftConnection** component, you must specify the property `loglevel=1/2/3` in the **Additional JDBC Parameters** field of the **tRedshiftConnection** component. There is no limitation on the size of the log file. If the specified log file already exists, it will be overwritten. |
| **Logging level** | Select a logging level from the drop-down list to specify which kind of events will be logged in the log file. |
| **Use cursor** | Select this check box to help to decide the row set to work with at a time and thus optimize performance. |
| **Trim all the String/Char columns** | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| **Trim column** | Remove leading and trailing whitespace from defined columns. |
| **JDBC url** | Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.  
  - **Standard**: Use the standard way to access the Redshift database.  
  - **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.  
This property is available only when **Use an existing connection** check box is not selected from the **Basic settings**. Once enabled, the **Username** and **Password** properties in **Basic settings** will be hidden, and then you should go to **Additional JDBC Parameters** to specify parameters for access. |
### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Amazon Redshift databases.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
<tr>
<td></td>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.</td>
</tr>
<tr>
<td></td>
<td>For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. |

---

3102
Handling data with Redshift

This scenario describes a Job that writes the personal information into Redshift, then retrieves the information in Redshift and displays it on the console.

The scenario requires the following six components:

- **tRedshiftConnection**: opens a connection to Redshift.
- **tFixedFlowInput**: defines the personal information data structure, and sends the data to the next component.
- **tRedshiftOutput**: writes the data it receives from the preceding component into Redshift.
- **tRedshiftInput**: reads the data from Redshift.
- **tLogRow**: displays the data it receives from the preceding component on the console.
- **tRedshiftClose**: closes the connection to Redshift.

Dropping and linking the components

Procedure

1. Drop the six components listed previously from the Palette onto the design workspace.
2. Connect tFixedFlowInput to tRedshiftOutput using a Row > Main connection.
3. Connect tRedshiftInput to tLogRow also using a Row > Main connection.
4. Connect tRedshiftConnection to tFixedFlowInput using a Trigger > OnSubjobOk connection.
5. Connect tFixedFlowInput to tRedshiftInput and tRedshiftInput to tRedshiftClose also using a Trigger > OnSubjobOk connection.
Configuring the components

Opening a connection to Redshift

Procedure

1. Double-click tRedshiftConnection to open its Basic settings view.

   ![tRedshiftConnection_1](image)

   2. Select Built-In from the Property Type drop-down list.

   In the Host, Port, Database, Schema, Username, and Password fields, enter the information required for the connection to Redshift.

   3. In Advanced settings view, select Auto Commit check box to commit any changes to Redshift upon each transaction.

Defining the input data

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.

   ![tFixedFlowInput_1](image)

   2. Click the [...] button next to Edit schema to open the schema editor.
3. In the schema editor, click the [+ ] button to add three columns: id of the integer type, name of the string type, and age of the integer type.

4. Click OK to validate the changes and accept the propagation prompted by the pop-up [Propagate] dialog box.

5. In the Mode area, select Use Inline Content (delimited file) and enter the following personal information in the Content field.

   1; Arthur; 16
   2; Ford; 18
   3; Jackson; 17

**Writing the data into Redshift**

**Procedure**

1. Double-click tRedshiftOutput to open its Basic settings view.

2. Select the Use an existing connection check box, and then select the connection you have already configured for tRedshiftConnection from the Component List drop-down list.

3. In the Table field, enter or browse to the table into which you want to write the data, redshiftexample in this scenario.

4. Select Drop table if exists and create from the Action on table drop-down list, and select Insert from the Action on data drop-down list.

5. Click Sync columns to retrieve the schema from the preceding component tFixedFlowInput.
Retrieving the data from Redshift

Procedure

1. Double-click **tRedshiftInput** to open its **Basic settings** view.

![Image of tRedshiftInput with settings](tRedshiftInput_1.png)

2. Select the **Use an existing connection** check box, and then select the connection you have already configured for **tRedshiftConnection** from the **Component List** drop-down list.

3. Click the [...] button next to **Edit schema** to open the schema editor.

4. In the schema editor, click the [+] button to add three columns: *id* of the integer type, *name* of the string type, and *age* of the integer type. The data structure is same as the structure you have defined for **tFixedFlowInput**.

5. Click **OK** to validate the changes and accept the propagation prompted by the pop-up [Propagate] dialog box.

6. In the **Table Name** field, enter or browse to the table into which you write the data, *redshiftexample* in this scenario.

7. Click the **Guess Query** button to generate the query. The **Query** field will be filled with the automatically generated query.

Displaying the defined information

Procedure

1. Double-click **tLogRow** to open its **Basic settings** view.

![Image of tLogRow with settings](tLogRow_1.png)

2. In the **Mode** area, select **Table (print values in cells of a table)** for a better view of the results.
Closing the connection to Redshift

Procedure

1. Double-click `tRedshiftClose` to open its Basic settings view.

2. From Component List, select the connection you have already configured for `tRedshiftConnection`.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to execute the Job.

```
Starting job DOCT3191_tRedshift_501 at 17:16 19/03/2014
[statistics] connecting to socket on port 3000
[statistics] connected
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
</tr>
<tr>
<td>---</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>
[statistics] disconnected
Job DOCT3191_tRedshift_501 ended at 17:16 19/03/2014. [exit code=0]
```

The personal information is written to the specified target Redshift database, and then the data is retrieved from the database and displayed on the console.
tRedshiftOutput

Writes, updates, modifies or deletes the data in a database.

tRedshiftOutput executes the action defined on the table and/or on the data of a table, according to the input flow from the previous component.

**tRedshiftOutput Standard properties**

These properties are used to configure tRedshiftOutput running in the Standard Job framework.

The Standard tRedshiftOutput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Database Connection Icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.</td>
</tr>
<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Database name. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to which the data will be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  **None**: No operation is carried out.  
  **Drop and create a table**: The table is removed and created again.  
  **Create a table**: The table does not exist and gets created.  
  **Create a table if not exists**: The table is created if it does not exist.  
  **Drop a table if exists and create**: The table is removed if already exists and created again.  
  **Clear a table**: The table content is deleted. |
Action on data

On the data of the table defined, you can perform:

**Insert**: Add new entries to the table. If duplicates are found, the operation will stop.

**Update**: Make changes to existing entries.

**Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.

**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning:** It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the **Update** operation. Do the same in the **Key in delete column** for the **Delete operation**.

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

**Built-In**: You create and store the schema locally for this component only. Related topic: see **Talend Studio User Guide**.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see **Talend Studio User Guide**.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon...
RedshiftOutput

Completion and choose this schema metadata again in the Repository Content window.

| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error through a Row > Rejects link. |

---

**Advanced settings**

| **Extend Insert** | Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable.  

**Number of rows per insert**: enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands.  

Amazon Redshift requires the number of rows per insert to be less than 32767. For this reason, if the number you enter exceeds this maximum limit, the Studio automatically resets this number below this limit.  

**Note**: This option is not compatible with the Reject link. You should therefore clear the check box if you are using a Row > Rejects link with this component. |

| **Use Batch** | Select this check box to activate the batch mode for data processing.  

**Note**: This check box is available only when you have selected the Update or the Delete option in the Action on data field. |

| **Batch Size** | Specify the number of records to be processed in each batch.  

This field appears only when the Use batch mode check box is selected. |

| **Commit every** | Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. |

| **Additional Columns** | This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.  

**Name**: Type in the name of the schema column to be altered or inserted as new column.  

**SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data. |
### tRedshiftOutput

<table>
<thead>
<tr>
<th>Position:</th>
<th>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Reference column:</td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td>Use field options:</td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
</tbody>
</table>
| **JDBC url** | Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.  
- **Standard**: Use the standard way to access the Redshift database.  
- **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.  
  This property is available only when **Use an existing connection** check box is not selected from the **Basic settings**. Once enabled, the **Username** and **Password** properties in **Basic settings** will be hidden, and then you should go to **Additional JDBC Parameters** to specify parameters for access. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
<td></td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in an Amazon Redshift database. It enables you to create a reject flow, with a Row &gt; Rejects link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2500.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

Related scenarios

For a related scenario, see Handling data with Redshift on page 3103.
tRedshiftOutputBulk

Prepares a delimited/CSV file that can be used by tRedshiftBulkExec to feed Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and then uploads the file to Amazon S3.

tRedshiftOutputBulk Standard properties

These properties are used to configure tRedshiftOutputBulk running in the Standard Job framework.

The Standard tRedshiftOutputBulk component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data file path at local</td>
<td>Specify the local path to the file to be generated. Note that the file is generated on the same machine where the Studio is installed or where the Job using this component is deployed.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
</tbody>
</table>
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Compress the data file</th>
<th>Select this check box and select a compression type from the list displayed to compress the data file. This check box disappears when the <strong>Append the local file</strong> check box is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Encrypt</td>
<td>Select this check box to generate and upload the data file to Amazon S3 using client-side encryption. In the <strong>Encryption key</strong> field displayed, enter the encryption key used to encrypt the file. By default, this check box is cleared and the data file will be uploaded to Amazon S3 using server-side encryption. For more information about the client-side and server-side encryption, see <strong>Protecting Data Using Encryption</strong>.</td>
</tr>
<tr>
<td>Access Key</td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit <strong>Getting Your AWS Access Keys</strong>.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the access key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see <strong>Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances</strong>.</td>
</tr>
</tbody>
</table>
| Assume role | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  - **Role session name**: an identifier for the assumed role session.  
  - **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see **AssumeRole**. |
| Region | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see **Regions and Endpoints**. |
| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, |
**Bucket**
Type in the name of the Amazon S3 bucket, namely the top level folder, to which the file is uploaded. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.

**Key**
Type in an object key to assign to the file uploaded to Amazon S3.

**Advanced settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Field Separator</td>
<td>Enter the character used to separate fields.</td>
</tr>
<tr>
<td>Text enclosure</td>
<td>Select the character in a pair of which the fields are enclosed.</td>
</tr>
<tr>
<td>Delete local file after putting it to s3</td>
<td>Select this check box to delete the local file after being uploaded to Amazon S3. By default, this check box is selected.</td>
</tr>
<tr>
<td>Create directory if not exists</td>
<td>Select this check box to create the directory specified in the Data file path at local field if it does not exist. By default, this check box is selected.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select an encoding type for the data in the file to be generated.</td>
</tr>
</tbody>
</table>
| Config client | Select this check box to configure client parameters for Amazon S3. Click the + button below the table displayed to add as many rows as needed, each row for a client parameter, and set the following attributes for each parameter:  
  - Client Parameter: Click the cell and select a parameter from the drop-down list.  
  - Value: Enter the value for the corresponding client parameter. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| NB_LINE | the number of rows processed. This is an After variable and it returns an integer.  
ERROR_MESSAGE | the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component is more commonly used with the tRedshiftBulkExec component to feed Amazon Redshift with a delimited/CSV file. Used together they offer gains in performance while feeding Amazon Redshift. |

### Related scenario

For a related scenario, see Loading/unloading data from/to Amazon S3 on page 3082.
tRedshiftOutputBulkExec

Executes the Insert action on the data provided.

As a dedicated component, it allows gains in performance during Insert operations to Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and uploads the file to Amazon S3, finally it loads the data from Amazon S3 to Redshift.

tRedshiftOutputBulkExec Standard properties

These properties are used to configure tRedshiftOutputBulkExec running in the Standard Job framework.

The Standard tRedshiftOutputBulkExec component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property Type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Type in the name of the schema.</td>
</tr>
</tbody>
</table>
### Username and Password
Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Additional JDBC Parameters
Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL.

### Table Name
Specify the name of the table to be written. Note that only one table can be written at a time.

### Action on table
On the table defined, you can perform one of the following operations:
- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Data file path at local
Specify the local path to the file to be generated.
<table>
<thead>
<tr>
<th><strong>tRedshiftOutputBulkExec</strong></th>
<th>Note that the file is generated on the same machine where the Studio is installed or where the Job using this component is deployed.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Append the local file</strong></td>
<td>Select this check box to append data to the specified local file if it already exists, instead of overwriting it.</td>
</tr>
<tr>
<td><strong>Create directory if not exists</strong></td>
<td>Select this check box to create the directory specified in the <strong>Data file path at local</strong> field if it does not exist. By default, this check box is selected.</td>
</tr>
<tr>
<td><strong>Access Key</strong></td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit <a href="#">Getting Your AWS Access Keys</a>.</td>
</tr>
<tr>
<td><strong>Secret Key</strong></td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see <a href="#">Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances</a>.</td>
</tr>
</tbody>
</table>
| **S3 Assume Role**          | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  - **Role session name**: an identifier for the assumed role session.  
  - **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see [AssumeRole](#). |
| **STS Endpoint**            | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.  
  This check box is available only when the **Assume role** check box is selected. |
| **Region**                  | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see [Regions and Endpoints](#). |
| **Bucket**                  | Type in the name of the Amazon S3 bucket, namely the top level folder, to which the file is uploaded.  
  The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further |
Information about these errors, see `S3ServiceException Errors`.

<table>
<thead>
<tr>
<th>Key</th>
<th>Type in an object key to assign to the file uploaded to Amazon S3.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Redshift Assume Role</strong></td>
<td>Select this check box and specify the values for the following parameters used to create a new assumed role session.</td>
</tr>
<tr>
<td>- <strong>IAM Role ARNs chains</strong>: A series of chained roles, which may belong to other accounts, that your cluster can assume to access resources. You can chain a maximum of 10 roles.</td>
<td></td>
</tr>
</tbody>
</table>
| - **Role ARN**: The Amazon Resource Name (ARN) of the role to assume. For more information on IAM Role ARNs chains, see `Authorizing Redshift service`.

### Advanced settings

<p>| Fields terminated by | Enter the character used to separate fields. |
| Enclosed by | Select the character in a pair of which the fields are enclosed. |
| Compressed by | Select this check box and select a compression type from the list displayed to compress the data file. This field disappears when the <strong>Append the local file</strong> check box is selected. |
| <strong>Encrypt</strong> | Select this check box to generate and upload the data file to Amazon S3 using client-side encryption. In the <strong>Encryption key</strong> field displayed, specify the encryption key used to encrypt the file. Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see <code>Loading Encrypted Data Files from Amazon S3</code>. By default, this check box is cleared and the data file will be uploaded to Amazon S3 using server-side encryption. For more information about the client-side and server-side encryption, see <code>Protecting Data Using Encryption</code>. |
| <strong>Encoding</strong> | Select an encoding type for the data in the file to be generated. |
| <strong>Delete local file after putting it to s3</strong> | Select this check box to delete the local file after being uploaded to Amazon S3. By default, this check box is selected. |
| <strong>Date format</strong> | Select one of the following items from the list to specify the date format in the source data: |
| - <strong>NONE</strong>: No date format is specified. |
| - <strong>PATTERN</strong>: Select this item and specify the date format in the field displayed. The default date format is <code>YYYY-MM-DD</code>. |
| - <strong>AUTO</strong>: Select this item if you want Amazon Redshift to recognize and convert automatically the date format. |</p>
<table>
<thead>
<tr>
<th><strong>Time format</strong></th>
<th>Select one of the following items from the list to specify the time format in the source data:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>NONE</strong>: No time format is specified.</td>
</tr>
<tr>
<td></td>
<td>• <strong>PATTERN</strong>: Select this item and specify the time format in the field displayed. The default time format is YYYY-MM-DD HH:MI:SS.</td>
</tr>
<tr>
<td></td>
<td>• <strong>AUTO</strong>: Select this item if you want Amazon Redshift to recognize and convert automatically the time format.</td>
</tr>
<tr>
<td></td>
<td>• <strong>EPOCHSECS</strong>: Select this item if the source data is represented as epoch time, the number of seconds since Jan 1, 1970 00:00:00 UTC.</td>
</tr>
<tr>
<td></td>
<td>• <strong>EPOCHMILLISECS</strong>: Select this item if the source data is represented as epoch time, the number of milliseconds since Jan 1, 1970 00:00:00 UTC.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Settings</strong></th>
<th>Click the [+] button below the table to specify more parameters for loading the data.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Parameter</strong>: Click the cell and select a parameter from the drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Value</strong>: Set the value for the corresponding parameter. Note that you cannot set the value for a parameter (such as <code>IGNOREBLANKLINES</code>) that does not need a value.</td>
</tr>
</tbody>
</table>

For more information about the parameters, see [http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html](http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html).

<table>
<thead>
<tr>
<th><strong>Config client</strong></th>
<th>Select this check box to configure client parameters for Amazon S3. Click the [+] button below the table displayed to add as many rows as needed, each row for a client parameter, and set the following attributes for each parameter:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Client Parameter</strong>: Click the cell and select a parameter from the drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Value</strong>: Enter the value for the corresponding client parameter.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>JDBC url</strong></th>
<th>Select a way to access to an Amazon Redshift database from the <strong>JDBC url</strong> drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Standard</strong>: Use the standard way to access the Redshift database.</td>
</tr>
<tr>
<td></td>
<td>• <strong>SSO</strong>: Use the IAM Single Sign-On (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.</td>
</tr>
</tbody>
</table>

This property is available only when **Use an existing connection** check box is not selected from the **Basic settings**. Once enabled, the **Username** and **Password** properties in **Basic settings** will be hidden, and then you should go to **Additional JDBC Parameters** to specify parameters for access.

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.                                                                                       |
Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

This component is mainly used when no particular transformation is required on the data to be loaded to Amazon Redshift.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2472 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 495. For more information on **Dynamic settings** and context variables, see *Talend Studio User Guide*.

Related scenario

For a related scenario, see *Loading/unloading data from/to Amazon S3* on page 3082.
tRedshiftRollback

Cancels the transaction commit in the Redshift database to avoid committing part of a transaction involuntarily.

tRedshiftRollback Standard properties

These properties are used to configure tRedshiftRollback running in the Standard Job framework. The Standard tRedshiftRollback component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the tRedshiftConnection and tRedshiftCommit components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection |
**Related scenario**

For a similar scenario, see *Rollback from inserting data in mother/daughter tables* on page 2455.
tRedshiftRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database.

The SQLBuilder tool helps you write easily your SQL statements.

tRedshiftRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it does not provide output.

**tRedshiftRow Standard properties**

These properties are used to configure tRedshiftRow running in the Standard Job framework.

The Standard tRedshiftRow component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 608.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| **Host** | Hostname or IP address of the database server. |
| **Port** | Listening port number of the database server. |
| **Database** | Name of the database. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors. |
| **Schema** | Exact name of the schema. |
| **Username and Password** | Database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Additional JDBC Parameters** | Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
<p>| <strong>Table Name</strong> | Name of the table from which the data will be read. |
| <strong>Query type</strong> | Either <strong>Built-in</strong> or <strong>Repository</strong>. <strong>Built-in</strong>: Fill in manually the query statement or build it graphically using SQLBuilder. <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |</p>
<table>
<thead>
<tr>
<th>Repository</th>
<th>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Guess Query</strong></td>
<td>Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td><strong>Query</strong></td>
<td>Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td><strong>Die on error</strong></td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error through a Row &gt; Rejects link.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>Propagate QUERY’s recordset</th>
<th>Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Use PreparedStatement</th>
<th>Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Parameter Index:</strong></td>
<td>Enter the parameter position in the SQL instruction.</td>
</tr>
<tr>
<td><strong>Parameter Type:</strong></td>
<td>Enter the parameter type.</td>
</tr>
<tr>
<td><strong>Parameter Value:</strong></td>
<td>Enter the parameter value.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This option is very useful if you need to execute the same query several times. Performance levels are increased.</td>
</tr>
</tbody>
</table>

| Commit every | Number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions. |

<table>
<thead>
<tr>
<th>JDBC url</th>
<th>Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Standard</strong></td>
<td>Use the standard way to access the Redshift database.</td>
</tr>
<tr>
<td><strong>SSO</strong></td>
<td>Use the IAM Single Sign-On (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate permissions.</td>
</tr>
</tbody>
</table>
access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This property is available only when Use an existing connection check box is not selected from the Basic settings. Once enabled, the Username and Password properties in Basic settings will be hidden, and then you should go to Additional JDBC Parameters to specify parameters for access.

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string. |
| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| Global Variables | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| Global Variables | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| Global Variables | For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component offers the flexibility benefit of the database query and covers all possible SQL queries. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
| Dynamic settings | The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
| Dynamic settings | For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic |
### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Related scenarios

For similar scenarios, see:

- **Combining two flows for selective output** on page 2529
- **Procedure** on page 635
- **Removing and regenerating a MySQL table index** on page 2523
tRedshiftUnload

Unloads data on Amazon Redshift to files on Amazon S3.
This component runs a specified query in Amazon Redshift and then unloads the result of the query to one or more files on Amazon S3.

**tRedshiftUnload Standard properties**

These properties are used to configure tRedshiftUnload running in the Standard Job framework.
The Standard tRedshiftUnload component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

**Basic settings**

<table>

<tr>
<td>Table Name</td>
<td>Type in the name of the table from which the data will be read.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see <em>Talend Studio User Guide</em>.</td>
<td></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query Type** and **Query**

Enter the database query paying particularly attention to the proper sequence of the fields in order to match the schema definition.

Double-escape each simple quotation marks in the query. For example,

```
SELECT name, birth,"Add" FROM my_table WHERE birth between \\
'2018-01-01 00:00:00\'
and \\
'2019-01-01 00:00:00\'
```

**Guess Query**

Click the button to generate the query which corresponds to the table schema in the **Query** field.

**Access Key**

Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit *Getting Your AWS Access Keys*.

**Secret Key**

Specify the Secret Access Key, constituting the security credentials in combination with the access Key.

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Assume Role**

Select this check box and specify the values for the following parameters used to create a new assumed role session.

- **IAM Role ARNs chains**: a series of chained roles, which may belong to other accounts, that your cluster can assume to access resources.
  
  You can chain a maximum of 10 roles.
- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.
## Advanced settings

**File type**
- Select the type of the unload files on Amazon S3 from the list:
  - Delimited file or CSV: a delimited/CSV file.
  - Fixed width: a fixed-width file.

**Fields terminated by**
- Enter the character used to separate fields.
  - This field appears only when Delimited file or CSV is selected from the File type list.

**Enclosed by**
- Select the character in a pair of which the fields are enclosed.
  - This list appears only when Delimited file or CSV is selected from the File type list.

**Fixed width mapping**
- Enter a string that specifies a user-defined column label and column width between double quotation marks. The format of the string is:
  ```plaintext
  ColumnLabel1:ColumnWidth1,ColumnLabel2:ColumnWidth2,...
  ```
  - Note that the column label in the string has no relation to the table column name and it can be either a text string or an integer. The order of the label/width pairs must match the order of the table columns exactly.
  - This field appears only when Fixed width is selected from the File type list.

**Compressed by**
- Select this check box and from the list displayed select the compression type of the files.

**Encrypt**
- Select this check box to encrypt unload file(s) using Amazon S3 client-side encryption. In the Encryption key field displayed, enter the encryption key used to encrypt the unload file(s). Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Unloading Encrypted Data Files.

**Specify null string**
- Select this check box and from the list displayed select a string that represents a null value in unload files.

**Escape**
- Select this check box to place an escape character (\) before every occurrence of the following characters for CHAR and VARCHAR columns in the delimited unload files: linefeed (\n), carriage return (\r), the delimiter character specified.
for the unloaded data, the escape character (\), a quote character (" or ").

<table>
<thead>
<tr>
<th>Overwrite s3 object if exist</th>
<th>Select this check box to overwrite the existing Amazon S3 object files.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parallel</td>
<td>Select this check box to write data in parallel to multiple unload files on Amazon S3 according to the number of slices in the Redshift cluster.</td>
</tr>
</tbody>
</table>
| JDBC url                              | Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.  
  - **Standard**: Use the standard way to access the Redshift database.  
  - **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.  
  This property is available only when Use an existing connection check box is not selected from the Basic settings. Once enabled, the Username and Password properties in Basic settings will be hidden, and then you should go to Additional JDBC Parameters to specify parameters for access. |
| tStatCatcher Statistics               | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
  For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component covers all possible SQL queries for the Amazon Redshift database. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an |
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related Scenario

For a related scenario, see Loading/unloading data from/to Amazon S3 on page 3082.
tReplace

 Cleanses all files before further processing.
Carries out a Search & Replace operation in the input columns defined.

**tReplace Standard properties**

These properties are used to configure tReplace running in the Standard Job framework.
The Standard tReplace component belongs to the Processing family.
The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| | • View schema: choose this option to view the schema only.
| | • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| | • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
| | Two read-only columns, Value and Match are added to the output schema automatically.
| Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide. |
| Simple Mode Search / Replace | Click the button to add as many conditions as needed. The conditions are performed one after the other for each row.
| Input column: Select the column of the schema the search & replace is to be operated on
| Search: Type in the value to search in the input column
| Replace with: Type in the substitution value.
<p>| Whole word: Select this check box if the searched value is to be considered as whole. |</p>
<table>
<thead>
<tr>
<th><strong>tReplace</strong></th>
<th><strong>Case sensitive</strong>: Select this check box to care about the case. Note that you cannot use regular expression in these columns.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use advanced mode</strong></td>
<td>Select this check box when the operation you want to perform cannot be carried out through the simple mode. In the text field, type in the regular expression as required.</td>
</tr>
</tbody>
</table>

### Advanced settings

- **tStatCatcher Statistics**: Select this check box to gather the job processing metadata at a job level as well as at each component level.

### Global Variables

- **Global Variables**
  - **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
  - **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

  For further information about variables, see [Talend Studio User Guide](#).

### Usage

- **Usage rule**: This component is not startable as it requires an input flow. And it requires an output component.

### Cleaning up and filtering a CSV file

This Job searches and replaces various typos and defects in a csv file then operates a column filtering before producing a new csv file with the final output.
- Drop the following components from the Palette onto the design workspace: `tFileInputDelimited`, `tReplace`, `tFilterColumn` and `tFileOutputDelimited`.
- Connect the components using Main Row connections via a right-click each component.
- Select the `tFileInputDelimited` component and set the input flow parameters.

- **File** is a simple CSV file stored locally. The **Row Separator** is a carriage return and the **Field Separator** is a semi-colon. In the **Header** is the name of the column, and no **Footer** nor **Limit** are to be set.
- The file contains characters such as: *t*, . or Nikson which we want to turn into Nixon, and streat, which we want to turn into Street.

<table>
<thead>
<tr>
<th>Street</th>
<th>FirstName</th>
<th>Name</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>streat</td>
<td>John</td>
<td>Kennedy</td>
<td>98.30$</td>
</tr>
<tr>
<td>streat</td>
<td>Richard</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>streat</td>
<td>Richard</td>
<td>Nikson</td>
<td>78.2$</td>
</tr>
<tr>
<td>streat</td>
<td>toto</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>streat</td>
<td>Richard</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>streat</td>
<td>Georges</td>
<td>t bush</td>
<td>99.99$</td>
</tr>
</tbody>
</table>

- **The schema for this file is built in also and made of four columns of various types (string or int).**
- **Now select the tReplace component to set the search & replace parameters.**

- The schema can be synchronized with the incoming flow.
- Select the **Simple mode** check box as the search parameters can be easily set without requiring the use of regexp.
- Click the plus sign to add some lines to the parameters table.
- On the first parameter line, select **Amount** as **InputColumn**. Type "," in the **Search** field, and "," in the **Replace** field.
• On the second parameter line, select Street as InputColumn. Type “street” in the Search field, and “Street” in the Replace field.

• On the third parameter line, select again Amount as InputColumn. Type “$“ in the Search field, and “£” in the Replace field.

• On the fourth parameter line, select Name as InputColumn. Type “Nikson” in the Search field, and “Nixon” in the Replace field.

• On the fifth parameter line, select Firstname as InputColumn. Type “t” in the Search field, and replace them with nothing between double quotes.

• The advanced mode isn’t used in this scenario.

• Select the next component in the Job, tFilterColumn.

The tFilterColumn component holds a schema editor allowing to build the output schema based on the column names of the input schema. In this use case, add one new column named empty_field and change the order of the input schema columns to obtain a schema as follows: empty_field, Firstname, Name, Street, Amount.

• Click OK to validate.

• Set the tFileOutputDelimited properties manually.

• The schema is built-in for this scenario, and comes from the preceding component in the Job.

• Save the Job and press F6 to execute it.
The first column is empty, the rest of the columns have been cleaned up from the parasitical characters, and Nikson was replaced with Nixon. The street column was moved and the decimal delimiter has been changed from a dot to a comma, along with the currency sign.
tReplaceList

Cleanses all files before further processing.
Carries out a Search and Replace operation in the input columns defined based on an external lookup.

tReplaceList Standard properties

These properties are used to configure tReplaceList running in the Standard Job framework.
The Standard tReplaceList component belongs to the Data Quality family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.
Two read-only columns, Value and Match are added to the output schema automatically.

| Warning: |
| The data Type defined in the schemas must be consistent, i.e., an integer can only be replaced by another integer using an integer as a look up field. Values of one type cannot be replaced by values of another type. |

| Built-in: The schema will be created and stored locally for this component only. Related topic: see Talend Studio User Guide. |

| Repository: The schema already exists and is stored in the Repository, hence can be reused in various projects and job designs. Related topic: see Talend Studio User Guide. |

| Lookup search column | Select the column to be searched in the lookup schema. |

| Lookup replacement column | Select the column where the replacement values are stored. |

| Column options | Select the columns of the main flow where the replacement is to be carried out. |

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |
Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tReplaceList is an intermediary component. It requires an input flow and an output component. |

Replacing state names with their two-letter codes

The following Job searches and replaces a list of states with their corresponding two-letter codes. The relevant codes are taken from a reference file placed as lookup flow in the Job.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: two tFileInputDelimited components, a tReplaceList and a tLogRow.
2. Connect the two tFileInputDelimited components to the tReplaceList component using Row > Main connections. Note that the link between the reference input component (the second tFileInputDelimited) and the tReplaceList component appears as a lookup row.
3. Connect the tReplaceList component to the tLogRow component using a Row > Main connection.
Configuring the components

Procedure

1. Double-click the first **tFileInputDelimited** component to open its **Basic settings** view and set the parameters of the main input flow, including the path and name of the file to read and the number of header rows to skip.

   ![tFileInputDelimited Component](image)

   In this example, the main input file provides a list of people names and US state names. The following shows an extract of the file content:

   name;state
   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
   Dwight Roosevelt;Mississippi
   Franklin Grant;Nebraska

2. Click the [...] button next to **Edit schema** to open the **Schema** dialog box and set the input schema. According to the structure of the main input file, the input schema should contain two columns: *name* and *state*. 
When done, click **OK** to close the dialog box and propagate the changes to the next component.

3. Define the properties of the second **tFileInputDelimited** component similarly.

   ![Image of tFileInputDelimited component](image)

   In this example, the reference input file provides a list of states and their two-letter codes. Accordingly, the reference input schema should have two columns: **state** and **code**.

4. Double-click the **tReplaceList** component to open its **Basic settings** view to set the operation to carry out.
5. From the **Lookup search column** list, select the column to be searched. In this use case, we want to carry out a search on the *state* column.

6. From the **Lookup replacement column** list, select the column containing the replacement values, *code* for the two-letter state codes in this example.

7. In the **Column options** table, select **Replace** check box for the *states* column, to replace the state names with their corresponding codes.

8. In the **tLogRow** component, select the **Table** check box for a better readability of the output.

**Executing the Job**

**Procedure**

Save the Job and press **F6** to execute it.

The state names have been replaced with their respective two-letter codes.
tReplicate

Duplicates the incoming schema into two identical output flows.
This component performs different operations on the same schema.

**tReplicate Standard properties**

These properties are used to configure tReplicate running in the Standard Job framework.
The Standard tReplicate component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

### Basic settings

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
Click **Sync columns** to retrieve the schema from the previous component in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. Related topic: see <strong>Talend Studio User Guide</strong>.</td>

</tr>
</tbody>
</table>

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|----------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is not startable (green background), it requires an Input component and an output component.</th>
</tr>
</thead>
</table>
| Connections | Outgoing links (from this component to another):
Row: Main.
Trigger: Run if; On Component Ok; On Component Error.
Incoming links (from one component to this one):
Row: Main; Reject;
For further information regarding connections, see Talend Studio User Guide. |

### Replicating a flow and sorting two identical flows respectively

The scenario describes a Job that reads an input flow which contains names and states from a CSV file, replicates the input flow, then sorts the two identical flows based on name and state respectively, and displays the sorted data on the console.

### Setting up the Job

#### Procedure

1. Drop the following components from the Palette to the design workspace: one tFileInputDelimited component, one tReplicate component, two tSortRow components, and two tLogRow components.
2. Connect tFileInputDelimited to tReplicate using a Row > Main link.
3. Repeat the step above to connect tReplicate to two tSortRow components respectively and connect tSortRow to tLogRow.
4. Label the components to better identify their functions.

**Configuring the components**

**Procedure**

1. Double-click the `tFileInputDelimited` component to open its **Basic settings** view in the **Component** tab.

   ![Source(tFileInputDelimited_1)](image)

   - **File name/Stream**: D:/Input/Names&States.csv
   - **Row Separator**: \n
2. Click the [...] button next to the **File name/Stream** field to browse to the file from which you want to read the input flow. In this example, the input file is `Names&States.csv`, which contains two columns: `name` and `state`.

   ```
   name;state
   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
   Dwight Roosevelt;Mississippi
   Franklin Grant;Nebraska
   ```

3. Fill in the **Header**, **Footer** and **Limit** fields according to your needs. In this example, type in 1 in the **Header** field to skip the first row of the input file.
4. Click **Edit schema** to define the data structure of the input flow.

![Schema of Source](image)

5. Double-click the first **tSortRow** component to open its **Basic settings** view.

![Sort by name(tSortRow_1)](image)

6. In the **Criteria** panel, click the [+] button to add one row and set the sorting parameters for the schema column to be processed. To sort the input data by name, select **name** under **Schema column**. Select **alpha** as the sorting type and **asc** as the sorting order.

For more information about those parameters, see **tSortRow Standard properties** on page 3572.

7. Double-click the second **tSortRow** component and repeat the step above to define the sorting parameters for the state column.
8. In the Basic settings view of each tLogRow component, select Table in the Mode area for a better view of the Job execution result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the Run tab.

![Execution](image)

The data sorted by name and state are both displayed on the console.
tREST

Serves as a REST Web service client.

The tREST component sends HTTP requests to a REpresentational State Transfer (REST) Web service provider and gets responses correspondingly.

**tREST Standard properties**

The Standard tREST component belongs to the Internet family.

**Note:**

To build Jobs that need to be deployed into the Talend Runtime, it is recommended to use the tRESTClient component which is best suited for the Talend Runtime.

For more information about the tRESTClient component, see tRESTClient on page 3155.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. This component always uses a built-in, read-only schema that contains two columns: - <strong>Body</strong>: stores the result from the server end. - <strong>ERROR_CODE</strong>: stores the HTTP status code from the server end when an error occurs during the invocation process. The specific meanings of the error codes are subject to definitions of your Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_status_codes. Click <strong>Edit Schema</strong> to view the schema structure.</th>
</tr>
</thead>
<tbody>
<tr>
<td>URL</td>
<td>Type in the URL address of the REST Web server to be invoked.</td>
</tr>
<tr>
<td>HTTP Method</td>
<td>From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions: - <strong>GET</strong>: retrieves data from the server end based on the given parameters. - <strong>POST</strong>: creates and uploads data based on the given parameters.</td>
</tr>
</tbody>
</table>
### tREST

- **GET**: retrieves the data based on the given parameters.
- **POST**: updates data based on the given parameters, or if the data does not exist, creates it.
- **PUT**: updates data based on the given parameters, or if the data does not exist, creates it.
- **DELETE**: removes data based on the given parameters.

### HTTP Headers

Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation.

For the specific definitions of HTTP headers, consult your REST Web service provider. For reference information, visit [en.wikipedia.org/wiki/List_of_HTTP_headers](http://en.wikipedia.org/wiki/List_of_HTTP_headers).

### HTTP Body

Type in the payload to be uploaded to the server end when the **POST** or **PUT** action is selected.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](http://www.talend.com).
Connect the first tREST to the second tREST using a Trigger > OnSubjobOK connection.

Double click the first tREST component to open its Basic settings view.

- Fill the URL field with the URL of the Web service you are going to invoke. Note that the URL provided in this use case is for demonstration purposes only and is not a live address.
- From the HTTP Method list, select POST to send an HTTP request for creating a new record.
- Click the plus button to add a line in the HTTP Headers table, and type in the appropriate name-value key pair, which is subject to definition of your service provider, to indicate the media type of the payload to send to the server end. In this use case, type in Content-Type and application/xml. For reference information about Internet media types, visit www.w3.org/Protocols/rfc2616/rfc2616-sec3.html#sec3.7.
- Fill the HTTP Body field with the payload to be uploaded to the server end. In this use case, type in <Customer><name>Steven</name></Customer> to create a record for a new customer named Steven.

Note:

If you want to include double quotation marks in your payload, be sure to use a backslash escape character before each of the quotation marks. In this use case, for example, type in <Customer><name>\"Steven\"</name></Customer> if you want to enclose the name Steven in a pair of double quotation marks.

Double click the second tREST component to open its Basic settings view.
• Fill the **URL** field with the same URL.
• From the **HTTP Method** list, select **GET** to send an HTTP request for retrieving the existing records.
• In the **Basic settings** view of each **tLogRow**, select the **Print component unique name in front of each output row** and **Print schema column name in front of each value** check boxes for better identification of the output flows.

• Save your Job and press **F6** to launch it.

The console shows that the first **tREST** component sends an HTTP request to the server end to create a new customer named **Steven**, and the second **tREST** component successfully reads data from the server end, which includes the information of the new customer you just created.
tRESTClient

Interacts with RESTful Web service providers by sending HTTP and HTTPS requests using CXF (JAX-RS) getting the corresponding responses.

This component integrates well with Talend Runtime to get HTTPS support, with more QoS features to be supported in time.

### tRESTClient Standard properties

These properties are used to configure tRESTClient running in the Standard Job framework.

The Standard tRESTClient component belongs to the ESB family.

The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th><strong>URL</strong></th>
<th>Type in the URL address of the REST server to be invoked. When the Use Service Locator check box is selected, this field will not show and the URL of the REST server will be obtained from the Service Locator server automatically.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Relative Path</strong></td>
<td>Enter the relative path of the REST server to be invoked. For example, if you want to access <a href="http://localhost:8888/services/Customers/list">http://localhost:8888/services/Customers/list</a>: If Use Service Locator is disabled: You can enter any of the first part of the address in the URL field, and the second part in the Relative Path field. For example, you can enter <a href="http://localhost:8888">http://localhost:8888</a> in URL and /services/Customers/list in Relative Path. You can also enter the full path of the REST server in URL and leave Relative Path blank. If Use Service Locator is enabled: The URL part will be given by the Service Locator. In this case, you need to know the URL part, and specify the rest part in Relative Path. This depends on the service you request. For example, on tRESTRequest, you specify REST Endpoint as <a href="http://localhost:8888/services">http://localhost:8888/services</a> and enable Use Service Locator. Then, if you want to use this service, on tRESTClient side, you should specify /customers/list in Relative Path.</td>
</tr>
<tr>
<td><strong>HTTP Method</strong></td>
<td>From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions: - GET: retrieves data from the server end based on the given parameters. - POST: uploads data to the server end based on the given parameters. - PUT: updates data based on the given parameters, or if the data does not exist, creates it.</td>
</tr>
</tbody>
</table>
| Content Type | - PATCH: modifies data partially based on the given parameters.  
- DELETE: removes data based on the given parameters. |
|-------------|------------------------------------------------------------------|
| **Content Type** | Select XML, JSON, or FORM according to the media type of the content to be uploaded to the server end.  
This list appears only when you select the POST, PUT, or PATCH HTTP method. |
| **Accept Type** | Select the media type the client end is prepared to accept for the response from the server end.  
Available options are XML, JSON, and ANY. When ANY is selected, the response message can be of any type and will be transformed into a string. |
| **Query parameters** | Specify the URI query parameters in the form of name-value pairs.  
This option is mostly used with the GET method. |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component.  
This component uses three built-in, read-only schemas.  
Click Edit Schema to view the schema structure. |
| **Input Schema** | Schema for the input data. This schema contains two columns:  
- **body**: stores the content of structured input data  
- **string**: stores the input content when it is, or is handled as, a string. |
| **Response Schema** | Schema for server response. This schema is passed onto the next component via a **Row > Response** link, and it contains three columns:  
- **statusCode**: stores the HTTP status code from the server end.  
- **body**: stores the content of a structured response from the server end.  
- **string**: stores the response content from the server end when it is, or is handled as, a string. |
| **Error Schema** | Schema for error information. This schema is passed onto the next component via a **Row > Error** link, and it contains two columns:  
- **errorCode**: stores the HTTP status code from the server end when an error occurs during the invocation process. The specific meanings of the errors codes are subject to definitions of your Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_status_codes. |
- **errorMessage**: stores the error message corresponding the error code.

### Use Service Locator

Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.

### Use Service Activity Monitor

Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.

### Use Authentication

Select this check box if authentication is required on the REST server end. Select the authentication type from:

- **Basic HTTP**: Fill the **Username** and **Password** fields with your credentials.
- **HTTP Digest**: Fill the **Username** and **Password** fields with your credentials.
- **SAML Token (ESB runtime only)**: Fill the **Username** and **Password** fields with your credentials.
- **OAuth2 Bearer**: Fill the **Bearer Token** field with a base64-encoded credential string.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Use Business Correlation

Select this check box to create a correlation ID in this component.

You can specify a correlation ID in the **Correlation Value** field. In this case the correlation ID will be passed on to the service it calls so that chained service calls will be grouped under this correlation ID. If you leave this field empty, this value will be generated automatically at runtime.

When this option is enabled, tRESTClient will also extract the correlation ID from the response header and store it in the component variable for further use in the flow.

### Die on error

This check box is selected to kill the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows.

### Advanced settings

#### Log messages

Select this check box to log the message exchange between the service provider and the consumer.

#### Enable WebClient Operation Reporting

If this check box is selected, a CXF endpoint property will be set on the client side which may be used by some outgoing CXF metrics interceptors, to track requests to services using their URL's.

The property set is `org.apache.cxf.resource.operation.name` and it contains service URL together with
the HTTP method name, for example GET:http://example.com:8080/service/.

If this check box is not selected, the property will not be set and some metrics will not be counted, which may increase the performance.

<table>
<thead>
<tr>
<th>Convert Response To DOM Document</th>
<th>Select this check box to convert the response from the server to document type. Clear this check box if you want the response to be handled as a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Convert Types To Strings</td>
<td>This option appears when Content Type is JSON, or Accept Type is JSON or any. Select this check box to convert all values in JSON to string between quotation marks. For example, with this option enabled, the JSON data:</td>
</tr>
<tr>
<td></td>
<td>&quot;root&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;test&quot;: 111</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td></td>
<td>will be changed to:</td>
</tr>
<tr>
<td></td>
<td>&quot;root&quot;: {</td>
</tr>
<tr>
<td></td>
<td>&quot;test&quot;: &quot;111&quot;</td>
</tr>
<tr>
<td></td>
<td>}</td>
</tr>
<tr>
<td>Drop JSON Request Root</td>
<td>This option appears when HTTP Method is POST, PUT or PATCH and Content Type is JSON. Select this check box to drop root JSON elements.</td>
</tr>
<tr>
<td>Wrap JSON Response</td>
<td>This option appears and is enabled by default when JSON is selected from the Accept Type list in the Basic settings view. With this check box selected, the response is wrapped with a root element. Clear this check box to remove the root element from the response.</td>
</tr>
<tr>
<td>HTTP Headers</td>
<td>Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation. For the specific definitions of HTTP headers, consult your REST Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_headers.</td>
</tr>
<tr>
<td>Disable chunked encoding</td>
<td>This option appears when HTTP Method is POST, PUT or PATCH. Select this check box to disable encoding the payload as chunks.</td>
</tr>
<tr>
<td>Service Locator Customer Properties</td>
<td>This option appears when Use Service Locator is enabled in the Basic settings tab. Click [+ ] to add as many properties as needed to the table. Enter the name and the value of each property in the Property Name field and the Property Value field respectively to identify the service.</td>
</tr>
<tr>
<td>Service Activity Customer Properties</td>
<td>This option appears when Use Service Activity Monitor is enabled in the Basic settings tab. Click [+ ] to add as many properties as needed to the table. Enter the name and the value of each property in the Property Name field and the Property Value field respectively to identify the service.</td>
</tr>
<tr>
<td>Connection timeout</td>
<td>Set the amount of time, in seconds, that the client will attempt to establish a connection before it times out. If set to</td>
</tr>
</tbody>
</table>
0, the client will continue to attempt to open a connection indefinitely. (default: 30)

This option only works in the Studio and for DI Job use cases. For ESB Deployments to Talend Runtime, this parameter will have no effect when the component is deployed in runtime. In the configuration file 
<TalendRuntimePath>/container/etc/org.apache.cxf.http.conduits-common.cfg, you need a URL which covers your service, for example, url = http://.* to handle both HTTP and HTTPS requests, and specify the client.ConnectionTimeout parameter in milliseconds in this HTTP Conduit file. If you need to use the **Receive timeout** option, specify the client.ReceiveTimeout in milliseconds too.

<table>
<thead>
<tr>
<th>Receive timeout</th>
<th>Set the amount of time, in seconds, that the client will wait for a response before it times out. If set to 0, the client will wait indefinitely. (default: 60) This option works similar to the <strong>Connection timeout</strong> for Studio, DI Use cases and ESB Runtime (OSGi / Microservice Deployments). For how to use it after the component is deployed in runtime or in Talend Administration Center, see the <strong>Connection timeout</strong> option.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Use HTTP proxy</th>
<th>Select this check box if you are using a proxy server. Once selected, you need to provide the connection details: host, port, username and password.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>HEADERS: the HTTP response headers. This is a Flow variable and it returns a list of HTTP response header values.</td>
</tr>
<tr>
<td></td>
<td>CORRELATION_ID: the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as a RESTful Web service client to communicate with a RESTful service provider, with the ability to input a request to a service into a Job and return the Job result as a service response. Depending on the actions to perform, it usually works as a start or middle component in a Job or subJob.</th>
</tr>
</thead>
</table>

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to turn on or off the Use Authentication or Use HTTP proxy option dynamically at runtime. You can add two rows in the table to set both options. Once a dynamic parameter is defined, the corresponding option becomes highlighted and unusable in the Basic settings view or Advanced settings view. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

| Connections | Outgoing links: Row: Response; Error. Trigger: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error. 

Incoming links: Row: Main; Reject. Trigger: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error. For further information regarding connections, see Talend Studio User Guide. |

| Limitation | Using context variables for dynamic endpoint or Service Locator namespace works in the Studio only. It is not supported in Runtime. |

### Getting user information by interacting with a RESTful service

This scenario describes a three-component Job that retrieves user information based on the user ID from a REST service via HTTP GET and displays the retrieved user information, as well as the message exchange between the client and the server, on the Run console.

**Prerequisites:**

If you are a Talend Open Studio for ESB user, create a Job as described in Using URI Query parameters to explore the data of a database on page 3182, run the Job to expose a REST service, and enter the REST service URL in your Web browser, http://localhost:8088/users in this example. You should see information like the following:
If you are not a Talend Open Studio for ESB user, then you need to get from your REST service provider the URL, the data structure, and the required parameters of the REST service you are going to call and make necessary modifications in the scenario configurations accordingly.

### Setting up the Job

**Procedure**

1. Drop the following components from the Palette onto the design workspace:
   - tRESTClient, used to call the REST service and retrieve user information from the server end,
   - tXMLMap, used to adapt the tree structure of the REST service, and
   - tLogRow, to display the retrieved user information on the Run console.
2. Connect the tRESTClient to the tXMLMap using a Row > Response connection.
3. Connect the tXMLMap to the tLogRow using a Row > Main connection, and give it a name, out in this example.
4. Label the components to best describe the actions to perform.

### Configuring the components

**Configuring the service call**

**Procedure**

1. Double-click the tRESTClient component to open its Basic settings view.
2. Fill the **URL** field with the URL of the REST service you are going to invoke, “http://localhost:8088/users” in this example. Note that the URL provided in this use case is for demonstration purposes only and not a live address.

3. From the **HTTP Method** list, select **GET** to send an HTTP request for retrieving the existing records.

   From the **Accept Type** list, select the type the client end is prepared to accept for the response from the server end, **XML**. Leave the rest of the settings as they are.

4. Click the [+] button beneath the **Query parameters** table to add two parameters, *from* and *to*, and set both parameters to 2, to get the information of the user with the ID of 2.

   Alternatively, you can query the information of the user with the ID of 2 by adding ?from=2&to=2 to the service URL.

5. In the **Advanced settings** view of the tRESTClient component, select the **Log messages** and the **Convert Response To DOM Document** check boxes to log the message exchange to the server and convert the response from the server to document type.

**Mapping the service structure and displaying the retrieved user information**

**Procedure**

1. Double-click the **tXMLMap** component to open the Map Editor.

2. If you selected **XML** in the **Accept Type** list of the tRESTClient component, define the input XML tree structure according to the service structure.

   a) In the input table, right-click the default *root* node of the *body* column, select **Rename** from the contextual menu, and rename it to **users**.
b) Right-click the users node, select **Create Sub-Element** from the contextual menu, and create sub-element named user. Set user as the loop element because the XML structure of the Web service to be invoked is looped on this element.

c) Right-click the user node, select **Create Attribute** from the contextual menu, and enter id in the **Create New Attribute** dialog box to create an attribute named id for the user node.

d) Right-click the user node again, select **Create Sub-Element** from the contextual menu, and enter first_name in the **Create New Element** dialog box to create an sub-element named first_name for the user node. Repeat this operation to create another sub-element under the user node, last_name.

e) Drop the id, first_name and last_name columns from the input table to the output table, and then click **OK** to validate the mapping and close the Map Editor.

If you selected **JSON** in the **Accept Type** list of the tRESTClient component, the response from the server end will be sent back in JSON format and converted to document type. In this example, the converted response structure looks like the following:

```xml
<root>
  <users>
    <user>
      <id>2</id>
      <first_name>Theodore</first_name>
      <last_name>Harding</last_name>
    </user>
  </users>
</root>
```
Note that the <root> element is removed if the Wrap JSON Response check box is cleared in the Advanced settings of the tRESTClient component.

Define the input XML tree structure accordingly and map it with the output data flow in a similar manner as described above.

3. Double-click the tLogRow component to open its Basic settings view.

4. Click the Sync columns button to make sure the component schema is synchronized with the output schema of the tXMLMap component.

5. In the Mode field, select the Table option to display the GET result in table cells.
Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run console to launch the Job.

   The console shows that the tRESTClient component successfully reads the user information from the server end corresponding to the specified user ID.

   If you selected XML in the Accept Type list of the tRESTClient component, the execution result will be:

   ![Execution Output]

   If you selected JSON in the Accept Type list of the tRESTClient component, the execution result will be:

   ![Execution Output]
Updating user information by interacting with a RESTful service

This scenario describes a three-component Job that updates the information of a list of users to a remote database through a REST service using the HTTP POST method. When executed, the Job displays the client-server message exchange information on the Run console.
The user information to be updated to the server is stored in a CSV file, which looks like the following:

| id;first_name;last_name |
|---|---|---|
| 1;John;Smith |
| 2;Martin;Reagan |
| 3;James;White |
| 4;Jenny;Jackson |
| 5;Robert;Thomson |

**Prerequisites:**

If you are a *Talend Open Studio for ESB* user, create a Job as described in *Using a REST service to accept HTTP POST requests* on page 3190 and run the Job as a REST server to expose a REST service that accepts HTTP POST requests. Upon execution of the Job, the console displays the service implementation information, including the service endpoint URL, which is http://localhost:8045/users in this example. If you enter http://localhost:8045/users?_wadl in your Web browser, you should see the service definition information like the following:

```xml
<application>
  <grammars/>
  <resources base="http://localhost:8045/users">
    <resource path="/"/>
    <resource path="post/(id)/(first_name)/(last_name)">
      <param name="last_name" style="template" type="xs:string"/>
      <param name="id" style="template" type="xs:int"/>
      <param name="first_name" style="template" type="xs:string"/>
      <method name="POST">
        <request/>
        <response>
          <representation mediaType="application/xml"/>
          <representation mediaType="text/xml"/>
          <representation mediaType="application/json"/>
        </response>
      </method>
    </resource>
    <resource/>
  </resources>
</application>
```

If you are not a *Talend Open Studio for ESB* user, then you need to get the service-related information from your REST service provider including the URL, the resource path, and the data structure, and make necessary modifications in the scenario configurations accordingly.
Setting up the Job

Procedure

1. Create a Job and add the following components by typing their names in the design workspace or drop them from the Palette:
   - tFileInputDelimited, to read user information of a local file,
   - tXMLMap, to adapt the input structure to the REST service structure, and
   - tRESTClient, used to call the REST service to send data to the remote database.

2. Connect the tFileInputDelimited to the tXMLMap using a Row > Main connection.

3. Connect the tXMLMap to the tRESTClient using a Row > Main connection, and give the output flow a name, request in this example.

4. Label the components to best describe the actions to perform.

Configuring the components

Configuring the input data and the structure mappings

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view.

2. Specify the input file in the File name field, fill the Header field with 1 to skip the header row, and keep the rest parameters as they are.

3. Click the [...] button next to Edit schema to open the Schema dialog box, and edit the input schema as follows:
   - id, type Integer, 2 characters long, set as the key column
   - first_name, type String
   - last_name, type String
4. Double-click the tXMLMap component to open the Map Editor.

5. Rename the root node in the output table: right-click the node, select Rename from the contextual menu, and specify a new name in the pop-up dialog box, user in this example.

6. Select all the three columns in the input table and drop them onto the user node, and select the Create as sub-element of target node option from the pop-up dialog box to set these columns as sub-elements of the user node. When done, click OK to validate the mappings and close the Map Editor.
Configuring the service call

Procedure

1. Double-click the tRESTClient component to open its Basic settings view.

![Image of tRESTClient component settings]

2. Fill the URL field with the URI location where the REST service is accessible, "http://localhost:8088/users" in this example.

3. In the Relative Path field, enter the resource path, "/post/" + row1.id + "/" + row1.first_name + "/" + row1.last_name in this example. This will send the data from the input row to the server end via the resource path.

4. From the HTTP Method list, select GET to send an HTTP request for retrieving the existing records.

5. From the Accept Type list, select the type the client end is prepared to accept for the response from the server end, XML.

5. In the Advanced settings view of the tRESTClient component, select the Log messages check box to log the message exchange information with the server.

   Leave the rest of the settings as they are.

Running the Job and checking the result

Press Ctrl+S to save your Job, and press F6 to execute it.

The console displays the client-server exchange information:
The console of the server Job displays the exchange information and the database update result.

tRESTRequest

Receives GET/POST/PUT/PATCH/DELETE requests from the clients on the server end.

tRESTRequest accepts the HTTP and/or HTTPS requests from the clients and supports GET, POST, PUT, PATCH and DELETE HTTP methods.

**Note:**
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the `org.ops4j.pax.web.cfg` file of your Runtime container before deploying the service on it. For more information, see the *Talend ESB Container Administration Guide*.

### tRESTRequest Standard properties

These properties are used to configure tRESTRequest running in the Standard Job framework.

The Standard tRESTRequest component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

#### Basic settings

| REST Endpoint                                      | Fill this field with the URI location where REST-ful web service will be accessible for requests. You can either specify an explicit port number, for example, "http://localhost:8088/services/customers", or use the default port of Talend and specify the relative path only, for example, "/services/customers". The default port is different depending on the build type or where you run the service:  
• To run the service inside Talend Studio: 8090  
• To run the service in a Talend Runtime Container: for HTTP 8040 is used for all services, and if HTTPS is enabled on Talend Runtime the service is also exposed on 9001.  
• To run the service as a Microservice: 8065 |
|-------------------------------------------------|--------------------------------------------------------------------------------------------------|
| REST API Mapping                                 | Click the [+] button beneath the mapping table to add lines to specify HTTP request:  
**Output Flow:** Click the [...] button to specify the name of an output flow and set the schema for that output flow in the dialog box afterwards.  
The schema is not mandatory, so if you do not need to pass additional parameters to the tRESTRequest component, you can leave the schema empty. However, you will have to populate the schema if you have URI Path parameters set in the URI Pattern field or if you need to add optional request parameters such as URI Query, HTTP Header or Form parameters, to the URI specified in the REST Endpoint field.  
Add a schema with the name body to get the request body of POST and PUT methods. It supports Document, String, and Byte types. |

3173
If you specify URI parameters in the output flow schema, you might need to define what type of parameter it is in the Comment field of the schema. By default, if you leave the Comment field empty, the parameter is considered as a Path parameter. Below is a list of supported Comment values:

- empty or path corresponds to the default `@PathParam`,
- `query` corresponds to `@QueryParam`,
- `form` corresponds to `@FormParam`,
- `header` corresponds to `@HeaderParam`.
- `matrix` corresponds to the CXF specific `@MatrixParam`.
- `multipart` corresponds to the CXF specific `@Multipart`, representing the request body. It can be used only with POST and PUT HTTP methods.

**Note:**

We recommend you to set the default values of your optional parameters (Header, Query, Form). To do so, fill in the Default columns of the schema.

| HTTP Verb | Select a HTTP method (GET/POST/PUT/PATCH/OPTIONS/DELETE/HEAD) from the list. |
| URI pattern | Fill this field with REST-ful URIs that describe the resource. |
| **Consumes** | Select the format type of the consume content that the component will use from XML or JSON, XML, JSON, Form, Multipart and Any in the list when the HTTP method is POST, PUT or PATCH. |
| **Produces** | When the HTTP method is GET, POST, PUT, PATCH, or DELETE, select the format type of the produce content that the component will use from XML or JSON, XML, JSON, HTML and Any, or select `<oneway>` in the list to accept one way requests. |
| **Streaming** | Select this check box to stream the response data by chunks so that the large volumes of data can be processed efficiently. |

**Use Service Locator**

Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.

**Use Service Activity Monitor**

Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.

**Use Authentication (ESB runtime only)**

Select this check box to enable the authentication option for the current service. This option works in runtime only. Select the authentication type from:

- **Basic HTTP**: The simplest technique for enforcing access controls to web resources using standard fields in the HTTP header.
- **SAML Token**: An XML-based, open-standard data format for exchanging authentication and au
| Use Business Correlation | Select this check box to enable the correlation option so that chained service calls will be grouped under the same correlation ID. tRESTRequest will extract the correlation ID from the request header and store it in the component variable for further use in the flow. If this option is not enabled on the client side, a correlation ID will be generated automatically in tRESTRequest. |

Advanced settings

| Log messages | Select this check box to log the message exchange between the service provider and the consumer. |
| Wrap JSON Request | Select this check box to wrap the JSON request with a root element. |
| Convert JSON values to String in response | Select this check box to convert the JSON values to string format in the response. |
| Service Locator Customer Properties | This option appears when Use Service Locator is enabled in the Basic settings tab. Click [+] to add as many properties as needed to the table. Enter the name and the value of each property in the Property Name field and the Property Value field respectively to identify the service. |
| Service Activity Customer Properties | This option appears when Use Service Activity Monitor is enabled in the Basic settings tab. Click [+] to add as many properties as needed to the table. Enter the name and the value of each property in the Property Name field and the Property Value field respectively to identify the service. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. URI: the URI of the REST request. This is a Flow variable and it returns a string. URI_BASE: the base URI of the REST request. This is a Flow variable and it returns a string. URI_ABSOLUTE: the absolute URI of the REST request. This is a Flow variable and it returns a string. HTTP_METHOD: the http method. This is a Flow variable and it returns a string. ATTACHMENT_HEADERS: the attachment headers from the REST request. This is a Flow variable and it returns a list of attachment header values. ATTACHMENT_FILENAMES: the attachment filenames from the REST request. This is a Flow variable and it returns all attachment filenames. |
Usage rule

This component covers the possibility that a Talend Job can be wrapped as a service, with the ability to input a request to a service into a Job and return the Job result as a service response.

The tRESTRequest component should be used with the tRESTResponse component to provide a Job result as a response, in case of a request-response communication style.

Limitation

Using context variables for dynamic endpoint or Service Locator namespace works in the Studio only. It is not supported in Runtime.

Using a REST service to accept HTTP GET requests and send responses

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes the process of accepting an HTTP request from the client, processing it and sending the response back.
Configuring the tRESTRequest component

Procedure

1. Drop the following components from the Palette onto the design workspace: a tRESTRequest, two tXMLMap and two tRESTResponse.

2. Double-click tRESTRequest in the design workspace to display its Basic settings view.

3. Fill the REST Endpoint field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://192.168.0.235:8088/user".

   **Note:** If you want your service to be available on both HTTP and HTTPS, fill the field with a relative path. For example, if you type in "/test", your service will be available on both http://<DefaultHTTPEndpointAddress>/test and https://<DefaultHTTPSEnpointAddress>/test, provided that you have configured your Runtime container to support HTTPS. For more information, see the Talend ESB Container Administration Guide.

4. Click the [+] button to add one line in the REST API Mapping table.
5. Select the newly-added line and click the [...] button in the **Output Flow** column to add a schema for the output flow. In this scenario, the output flow will be named as *GetOneUser*.

![Output Flow Table]

Then click the [+] button to add a new line *id* to the schema in the dialog box.

6. Click **OK** to save the schema.

7. Select **GET** from the list in the **HTTP Verb** column.

8. Fill the field in the **URI Pattern** column with "/{id}".

9. In the same way, add another line in the **REST API Mapping** table and name this schema *GetUserNumber*. Add a line *string* of **String** type to the schema. Enter *query* in the **Comment** field to get the number parameter in the request.

![REST API Mapping Table]

Select **GET** from the list in the **HTTP Verb** column. Fill the field in the **URI Pattern** column with " /number".

### Configuring the first **tXMLMap** component

**Procedure**

1. Connect **tRESTRequest** to a **tXMLMap** using the **Row > GetOneUser** connection.
2. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
3. Click the [+] button on the top right to add an output and name it as `ResponseUsers`.
4. Click the [+] button on the bottom right to add two columns for the output.
   Name the first column as `body` and set the Type to `Document`.
   Name the second column as `string` and set the Type to `String`.
5. Right-click on the node `root` and select `Create Sub-Element` to create a sub-element. Name the sub-element as `foo` in the popup dialog box.
6. Right-click on the `foo` node created in the previous step and select `As loop element`.
7. Select the `id` column of the `GetOneUser` table to the left and drop it onto the Expression field of the `foo` node of the `ResponseUsers` table to the right.
8. Click OK to save the settings.

**Configuring the second tXMLMap component**

**Procedure**

1. Connect `tRESTRequest` to the other `tXMLMap` using the Row > GetUserNumber connection.
2. Double-click the first `tXMLMap` in the design workspace to open the Map Editor.
3. Click the [+ ] button on the top right to add an output and name it as ResponseUserNumber.
4. Click the [+ ] button on the bottom right to add one column for the output.
   Name the first column as body and set the Type to Document.
5. Right-click on the node root and select Create Sub-Element to create a sub-element. Name the sub-element as number in the popup dialog box.
6. Right-click on the number node created in the previous step and select As loop element.
7. Select the string column of the GetUserNumber table to the left and drop it onto the Expression field of the number node of the ResponseUserNumber table to the right.
8. Click OK to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect tXMLMap to a tRESTResponse using Row > ResponseUsers connection. The schema defined in tXMLMap is retrieved in tRESTResponse automatically.

2. Select OK(200) from the Return status code list.
3. Leave the rest of the settings as they are.
4. Connect tRESTRequest to the other tRESTResponse using the Row > GetUserNumber connection.

**Saving and executing the Job**

**Procedure**

1. Save the Job and press F6 to execute it.

   ```
   [statistics] connecting to socket on port 8888
   [statistics] connected
   INFO : org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8088/user
   SelectChannelConnector@localhost:8088
   ```

2. Go to your browser if you want to test the service.

   ![Browser screenshot](image1)
   ![Browser screenshot](image2)

   The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

   You can see that 123 is returned in the response.

   ![Browser screenshot](image3)
Using URI Query parameters to explore the data of a database

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to use URI query parameters in tRESTRequest to explore data of a database, and send the response via the tRESTResponse.

To do so, you can create two subjobs linked together by an OnSubjobOk connection; this way the two subjobs will be executed sequentially. For more information on Trigger connection, see the Talend Studio User Guide. The first subjob will create and populate the database and the second one will allow to explore the database through the REST service.

Creating the first subJob

About this task

To do this, proceed as follows:

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput from the Misc family and tMysqlOutput from the Databases > Mysql family.
2. Link tFixedFlowInput to tMysqlOutput using a Row > Main connection.
3. Double-click **tFixedFlowInput** to display its **Basic settings** view:

4. Click the [...] button next to **Edit schema** to open the schema editor.

5. In the schema editor, click the [+ ] button three times to add three lines and set them as displayed in the above screenshot.

6. Click **Ok**.

7. Back to **tFixedFlowInput Basic settings** view, in the **Mode** area, select the **Use inline table** option.

8. Under the inline table, click the [+ ] button three times to add three rows in the table.

9. In the inline table, click the **id** field of the first row and type in **1**.

10. Click the **firstname** field of the first row, press **Ctrl+Space** to display the autocompletion list and select the **TalendDataGenerator.getFirstName()** variable in the list.

11. Click the **lastname** field of the first row, press **Ctrl+Space** to display the autocompletion list and select the **TalendDataGenerator.getLastName()** variable in the list.

12. Do the same for the two following rows to obtain the settings displayed in the screenshot.
13. Double-click tMysqlOutput to display its Basic settings view:

14. From the Property Type list, leave Built-in and fill in the Host, Port, Database, Username and Password fields manually. If you centralized your connection information to the database in the Metadata > DB Connections node of the Repository, you can select Repository from the list and the fields will be automatically filled in.

   For more information about storing metadata, see Talend Studio User Guide.

15. In the Table field, type in the name of the table in which the data will be loaded, for example: users.

16. From the Action on table list, select Drop table if exists and create, select Insert from the Action on data list.

17. Click Sync columns to retrieve the schema coming from the previous component.

Creating the second subJob

The following components are used as displayed in the first screenshot:

- tRESTRequest and tRESTResponse from the ESB > REST family,
- tFlowToIterate from the Orchestration family,
- tMysqlInput from the Databases > Mysql family,
- tXMLMap from the Processing family.

Configuring the tRESTRequest component

About this task

To do this, proceed as follows:
Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view:

   ![tRESTRequest settings](image)

   - REST Endpoint field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://localhost:8088/users".

2. Fill the REST Endpoint field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://localhost:8088/users".

3. Click the [+] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow.

5. In the dialog box, name the output flow getUsers. A schema editor dialog box appears.

   ![Schema editor](image)

   - In the schema editor, click the [+] button twice to add two lines and set them as displayed in the above screenshot.

6. Click OK.

7. Back to tRESTRequest Basic settings view, select GET from the list in the HTTP Verb column.

8. Leave the URI Pattern column as is.

9. Use the corresponding link to connect to the following component: connect tRESTRequest to tFlowToIterate using Row > getUsers connection.
11. Leave the **tFlowToIterate** settings as is.
12. Connect **tFlowToIterate** to **tMysqlInput** using **Row > Iterate** connection.

**Configuring the tMysqlInput component**

**About this task**

To do this, proceed as follows:

**Procedure**

1. Double-click **tMysqlInput** to display its **Basic settings** view:

   ![Basic settings view of tMysqlInput](image)

   2. From the **Property Type** list, leave **Built-in** and fill in the **Host**, **Port**, **Database**, **Username** and **Password** fields manually. If you centralized your connection information to the database in the **Metadata > DB Connections** node of the **Repository**, you can select **Repository** from the list and the fields will be automatically filled in.

   For more information about storing metadata, see [Talend Studio User Guide](#).

   3. Leave the **Schema** list as **Built-in** and click the [...] button next to the **Edit schema** field.

   4. In the schema editor, define the schema exactly like the one of the **tFixedFlowInput**.

   5. In the **Table Name** field, fill in the name of the table in which the data are stored: **users**.

   6. Leave the **Query Type** list as **Built-in** and fill in the **Query** field with the following SQL query allowing to explore the database data with the URI query set in the **tRESTRequest** component:

      ```sql
      "select * from users where id >= " + globalMap.get("getUsers.from") + " and id <= " + globalMap.get("getUsers.to")
      ```

   **Configuring the tXMLMap component**

   **Procedure**

   1. Right-click **tMysqlInput**, hold and drag to **tXMLMap** to connect the two components together.
2. Double-click `tXMLMap` in the design workspace to open the Map Editor.

3. Click the `+` button on the top right to add an output and name it as `ResponseUsers`.

4. Click the `+` button on the bottom right to add two columns for the output.
   Name the first column as `body` and set the Type to `Document`.
   Name the second column as `string` and set the Type to `String`.

5. Right-click on the root node, select Rename in the list and rename it `users`.

6. Right-click on the `users` node and select Create Sub-Element to create a sub-element. Name the sub-element `user` in the popup dialog box.

7. Right-click on the `user` node created in the previous step and select As loop element.

8. Select the `id` column of the `row2` table to the left and drop it onto the `user` node of the `ResponseUsers` table to the right.

9. In the Selection dialog box, select the Create as attribute of target node option and click OK.

10. Select the `firstname` and `lastname` columns of the `row2` table to the left and drop it onto the `user` node of the `ResponseUsers` table to the right.
11. In the Selection dialog box, select the **Create as sub-element of target node** option and click **OK**.

12. Click the wrench icon on the top of the **ResponseUsers** table to open the setting panel.

13. Set the **All in one** feature as **true**, this way all XML data is outputted in one single flow.

14. Click **OK** to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect **tXMLMap** to **tRESTResponse** using **Row > ResponseUsers** connection.

2. The schema defined in **tXMLMap** is retrieved in **tRESTResponse** automatically. Leave the other settings as they are.
Connecting the two subJobs

About this task

Now that the two subJobs are created, you can connect them together:

Procedure

1. Right-click the `tFixedFlowInput` component of the first subjob.
2. Select Trigger > OnSubjobOk on the list.
3. Click the `tRESTRequest` component of the second subJob.

Results

This way, when executing the job, the second subJob will be executed only if the first one’s execution succeeded.

Saving and executing the Job

Procedure

1. Save the Job and press F6 to execute it.

```
[statistics] connecting to socket on port 4020
[statistics] connected
[INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:9080/users
[INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
SelectChannelConnector@localhost:8088
```

2. Go to your browser if you want to test the service.
   For example, use the URI query `?to=2` to retrieve the data of the two first users.
The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

For a use case that calls this REST service using Talend Open Studio for ESB components, see Getting user information by interacting with a RESTful service on page 3160.

**Using a REST service to accept HTTP POST requests**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes a Job composed of two subjobs: the first subjob exposes a REST service that accepts HTTP POST requests from REST clients, writes data to a database upon receiving an HTTP request, and displays the server-client exchange information on the **Run** console; the second subjob displays the results of database updates.
### Setting up the Job

**Procedure**

1. Create a Job and add the following components to the Job by typing their names in the design workspace or dropping them from the Palette: a `tRESTRequest`, a `tMysqlOutput`, a `tXMLMap`, and a `tRESTResponse`.

2. Connect the `tRESTRequest` to the `tMysqlOutput` component using a Row > Main connection, and give the output flow a name, `request` in this example.

3. Connect the `tMysqlOutput` component to the `tXMLMap` component using a Row > Main connection.

4. Connect the `tXMLMap` component to the `tRESTResponse` component using a Row > Main connection, and give it a name, `response` in this example. Click OK in the pop-up dialog box to accept the schema propagation from the `tRESTResponse` component.

5. Add a `tMysqlInput` component and a `tLogRow` component to the Job by typing their names in the design workspace or dropping them from the Palette, and connect the `tMysqlInput` to the `tLogRow` using a Row > Main connection.

6. Connect the `tMysqlOutput` to the `tMysqlInput` using a Trigger > OnComponentOk connection to link the two subjobs.

### Configuring the components

#### Configuring REST request parameters

**Procedure**

1. Double-click the `tRESTRequest` component to open its Basic settings view.

2. Fill the REST Endpoint field with the URI location where the REST service will be accessible for requests, "http://localhost:8045/users" in this example.

3. Click the output flow name, which is `request` in this example, in the Output Flow column of the REST API Mapping table to show the [...] button, and click the button to open the Schema dialog box. Then define the schema for the request flow as follows:
   - `id`, type Integer, 2 characters long, set as the key column
   - `first_name`, type String
   - `last_name`, type String
When done, click OK to validate the schema setting and close the dialog box.

4. Click the **HTTP Verb** column and select **POST** from the list.

5. In the **URI Pattern** column, enter the acceptable URI pattern of POST requests, "/{id}/first_name/{last_name}" in this example. Leave the rest parameters as they are.

6. Click the **Advanced settings** tab, and select the **Log messages** check box.

### Configuring the database and the response parameters

#### Procedure

1. Double-click the **tMysqlOutput** component to open its **Basic settings** view.

2. Leave the **Property Type** as **Built-in** and fill in the database connection details manually in the **Host**, **Port**, **Database**, **Username** and **Password** fields.

   If you have centralized your connection information to the database in the **Metadata > DB Connections** node of the **Repository**, you can select **Repository** from the **Property Type** list and browse to the centralized connection to have the fields automatically filled in. For more information about storing metadata, see **Talend Studio User Guide**.
3. Fill in the **Table** field with the target database table name, *users* in this example.

4. Select the actions to be carried out on the database table and data according to your needs from the corresponding lists. In this example, the target table will be created if it does not exist in the specified database, and data from client requests will be inserted, or updated if it already exists, to the database table.

5. Click the **Sync columns** button to synchronize the table schema with the input schema.

6. Double-click the **tXMLMap** component to open the Map Editor.

7. Rename the **root** node in the output table: right-click the node, select **Rename** from the contextual menu, and specify a new name in the pop-up dialog box, *user* in this example.

8. Select all the three columns in the input table and drop them onto the *user* node, and select the **Create as sub-element of target node** option from the pop-up dialog box to set these columns as sub-elements of the *user* node. When done, click **OK** to validate the mappings and close the Map Editor.

9. Double-click the **tRESTResponse** component and set the response parameters according to your needs. In this example, we keep the default settings for all the parameters.

**Configuring result display**

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Specify the database connection details, table name and table schema, which are the same as in the tMysqlOutput component.

3. Click the Guess Query button to fill the Query field with the query statement.

4. Double-click the tLogRow component and select the Table option to display the content of the database in table cells.

**Saving the executing the Job**

**Procedure**

1. Press Ctrl+S to save your Job.

2. Click the Run button on the Run tab or press F6 to run it.

   The console displays the service implementation information, including the service URL.

   ```
   [statistics] connecting to socket on port 3306
   [statistics] connected
   [INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to http://localhost:8045/users
   [INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
   SelectChannelConnector=localhost:8045
   ```

   When an HTTP POST request is received from a client, the console displays the relevant exchange information and the database update result.
Using a REST service to accept HTTP POST requests and send responses

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to build a REST service that accepts HTTP POST requests of Document type from the client, processes it and sends the response back. To do this, two Jobs are built: one to create the REST service and the other to call it.

Creating the REST service Job

Drag and drop the following components from the Palette onto the design workspace: a tRESTRequest, a tXMLMap and a tRESTResponse.
Configuring the tRESTRequest component

Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view.

2. In the REST Endpoint field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow. Give the name for the schema UserInfo in this scenario.

The schema editor opens. Click the [+] button to add a new line body of Document type and click OK to save the schema.
5. Back to **tRESTRequest Basic settings** view, select **POST** from the list in the **HTTP Verb** column.
6. Fill the field in the **URI Pattern** column with ‘/UserInfo’. Keep the default settings of the other options.

**Configuring the body of the response**

**Procedure**

1. Connect **tRESTRequest** to **tXMLMap** using the **Row > UserInfo** connection.
2. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
3. Right-click on the root node of the input table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

4. Right-click on the person node created in the previous step and select As loop element.

5. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id and name in this use case.

6. Click the [+ ] button on the top right to add an output and name it as Response.

7. Click the [+ ] button on the bottom right to add a column body of Document type for the output.

8. Right-click the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

9. Right-click the person node created in the previous step and select As loop element.

10. Create three sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, name and company in this use case.

11. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

12. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.

   Click the Expression field of the name node in the output table, and click [...] in this field to show the Expression Builder wizard.

   In the Expression area, enter StringHandling.UPCASE([UserInfo.body:/root/person/name]) to convert the name of the user to upper case. Click OK to close the wizard.

13. In the Expression field of the company node, enter “Talend”.

14. Click OK to save the settings.

Configuring the tRESTResponse component

Procedure

1. Connect tXMLMap to a tRESTResponse using Row > Response connection.

   The schema defined in tXMLMap is retrieved in tRESTResponse automatically.

For further information about using the Expression Builder, see Talend Studio User Guide.
2. Select **OK(200)** from the **Return status code** list.
3. Leave the rest of the settings as they are.

**Launching the service**

Save the Job and press **F6** to execute it. The service is started.

**Creating the consumer Job**

Drag and drop the following components from the **Palette** onto the design workspace: a **tFixedFlowInput**, a **tXMLMap**, a **tRESTClient** and a **tLogRow**.

**Configuring the tFixedFlowInput component**

**Procedure**

1. Double-click **tFixedFlowInput** in the design workspace to display its **Basic settings** view.
2. Click **Edit schema** to show the schema editor. In the schema editor, click the [+] button to add two columns of **String** type, **id** and **name**. Click **Ok** to close the schema editor.

3. Back to **tFixedFlowInput** Basic settings view, in the **Mode** area, select the **Use Inline Content** option.

4. In the **Content** box, enter the **id** and **name** of three users, for example:

   ```
   1;ford
   2;smith
   3;thomson
   ```

**Configuring the tXMLMap component**

**Procedure**

1. Connect **tFixedFlowInput** to **tXMLMap** using the **Row > Main** connection.

2. Connect **tXMLMap** to **tRESTClient** using the **Row > Main** connection, and name the output flow **request** in this example.

3. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
4. Right-click on the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

5. Right-click on the person node created in the previous step and select As loop element.

6. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, and name in this use case.

7. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

8. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.

9. Click OK to save the settings.

Configuring the tRESTClient component

Procedure

1. Double-click the tRESTClient component to open its Basic settings view.
2. Fill the URL field with the URL of the REST service built in the service Job, "http://localhost:8088/".

3. Fill the Relative Path with the "UserInfo".

4. From the HTTP Method list, select POST.

5. Leave the rest of the settings as they are.

6. Connect tRESTClient to tLogRow using the Row > Response connection. Keep the default settings of the tLogRow to monitor the message exchanges.

**Saving and executing the Job**

Save the Job and press F6 to execute it. The user information is shown in the console, including id, name, and company. The name of the user has been converted to upper case.
Using a REST service to accept HTTP POST requests in an HTML form

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to upload data to a REST service using HTTP POST in a HTML form file. To do so, a Job is created to accept HTTP POST requests using the `tRESTRequest` component.

A predefined HTML form `UploadFile.html` is used to upload data to the REST service:

```
<form action="http://localhost:8088/UserInfo" method="post" enctype="multipart/form-data">
  <input type="file" name="id" />
  <button>upload</button>
</form>
```

The `customer.xml` that contains a user ID will be uploaded:

```
<customer>
  <id>100</id>
</customer>
```

**Setting up the Job**

Drop the following components from the Palette onto the design workspace: a `tRESTRequest`, a `tJavaRow`, a `tXMLMap` and a `tRESTResponse`. 

```java
[statistics] connecting to socket on port 3450
[statistics] connected
200 | <?xml version="1.0" encoding="UTF-8"?>
 <root><person><id>1</id><name>FORD</name><company>Talend</company></person></root>
200 | <?xml version="1.0" encoding="UTF-8"?>
 <root><person><id>2</id><name>SMITH</name><company>Talend</company></person></root>
200 | <?xml version="1.0" encoding="UTF-8"?>
 <root><person><id>3</id><name>THOMSON</name><company>Talend</company></person></root>
[statistics] disconnected
```
Configuring the tRESTRequest component

Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view.

2. In the REST Endpoint field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow. Give the name for the schema UserInfo in this scenario.

   The schema editor opens. Click the [+] button to add a new line id of byte[] type and enter multipart in the Comment field. Click OK to save the schema.

5. Back to tRESTRequest Basic settings view, select POST from the list in the HTTP Verb column.

6. Fill the field in the URI Pattern column with "/UserInfo".

7. Select Multipart in the Consumes list. Keep the default settings of the other options.
Configuring the tJavaRow component

Procedure

1. Connect tRESTRequest to tJavaRow using the Row > UserInfo connection.
2. Double-click tJavaRow in the design workspace to display its Basic settings view.

3. Enter the following code in the Code box to convert the message into Document type and print it in the console.

```java
String result = new String(input_row.id, 0, input_row.id.length);
routines.system.Document doc = new routines.system.Document();
doc.setDocument(org.dom4j.DocumentHelper.parseText(result));
output_row.id = doc;
System.out.println(result);
```

Configuring the tXMLMap component

Procedure

1. Connect tJavaRow to tXMLMap using the Row > Main connection.
2. Double-click tXMLMap in the design workspace to open the Map Editor.
3. Click the [+] button on the bottom left to add a column *id* of Document type for the input.

4. Right-click the root node of the input table and select Rename in the contextual menu and rename it *customer*.

5. Create a sub-element to the *customer* node by selecting Create Sub-Element in the contextual menu. Name the sub-element as *id* in the pop-up dialog box.

6. Click the [+] button on the top right to add an output and name it as *response*.

7. Click the [+] button on the bottom right to add a column *body* of Document type for the output.

8. Right-click the root node of the input table and select Rename in the contextual menu and rename it *customer*.

9. Create a sub-element to the *customer* node by selecting Create Sub-Element in the contextual menu. Name the sub-element as *id* in the pop-up dialog box.

10. Select the *id* column from the input table and drop it onto the Expression field of the *id* node of the output table.

11. Click OK to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect tXMLMap to a tRESTResponse using Row > response connection. The schema defined in tXMLMap is retrieved in tRESTResponse automatically.
2. Select **OK(200)** from the **Return status code** list.
3. Leave the rest of the settings as they are.

**Saving and executing the Job**

**Procedure**

1. Save the Job and press **F6** to execute it.

2. Run the **UploadFile.html** using a web browser.

3. Click the **Browse** button to navigate to the **customer.xml** that contains the user ID and click **upload**.
4. The HTTP POST request is accepted by the REST service and the user ID is sent back to the server.

You can also view the response in the page source.

5. The content of the input file is printed in the execution console.

   <id>100</id>
  </customer>
tRESTResponse

Returns a specific HTTP status code to the client end as a response to the HTTP and/or HTTP requests.

Note:
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the org.ops4j.pax.web.cfg file of your Runtime container. For more information, see the Talend ESB Container Administration Guide.

tRESTResponse Standard properties

These properties are used to configure tRESTResponse running in the Standard Job framework.

The Standard tRESTResponse component belongs to the ESB family.

This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).

Basic settings

<table>
<thead>
<tr>
<th>Return Body Type</th>
<th>Select a response body type from Document, String, and Byte in the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return status code</td>
<td>Select a status code from the list to indicate the request status.</td>
</tr>
<tr>
<td></td>
<td>- &lt;&lt;Custom&gt;&gt;: This option allows you to customize the status code. Enter the status code of your choice in the field.</td>
</tr>
<tr>
<td></td>
<td>- Bad Request (400): The request had bad syntax or was inherently impossible to be satisfied.</td>
</tr>
<tr>
<td></td>
<td>- Internal Server Error (500): The server encountered an unexpected condition which prevented it from fulfilling the request.</td>
</tr>
<tr>
<td></td>
<td>- OK (200): The request was fulfilled.</td>
</tr>
<tr>
<td></td>
<td>- Resource Not Found (404): The server has not found anything matching the URI given.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description, that is, it defines the number of fields to be processed and passed on to the next component.</td>
</tr>
<tr>
<td></td>
<td>The schema mode is Built-in: it is created and stored locally for this component.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema.</td>
</tr>
<tr>
<td></td>
<td>The input flow is retrieved from the previous component connected to tRESTResponse. Any change of the input flow in tRESTResponse will also be propagated to the previous component automatically.</td>
</tr>
<tr>
<td></td>
<td>The output flow of tRESTResponse is a hard-coded field named body, the type of which is defined in the Return Body Type list.</td>
</tr>
</tbody>
</table>

</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component covers the possibility that a Talend Job can be wrapped as a service, with the ability to input a request to a service into a Job and return the Job result as a service response.</td>
<td>The tRESTResponse component should only be used with the tRESTRequest component to provide a Job result as response for a web service provider, in case of a request-response communication style.</td>
</tr>
</tbody>
</table>

Related scenario

For a scenario in which tRESTResponse is used, see [Using a REST service to accept HTTP GET requests and send responses](http://www.talend.com) on page 3176.
tRiakBucketList

Retrieves a list of buckets from a Riak cluster and iterates on it.

**tRiakBucketList Standard properties**

These properties are used to configure tRiakBucketList running in the Standard Job framework.

The Standard tRiakBucketList component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</th>
</tr>
</thead>
</table>
| Nodes                      | Fill in the information required for a connection to a Riak cluster.  
  • **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.  
  • **Port**: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.  
  • **Riak path**: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.  
  One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak.  
  For more information about the concepts related to Riak, see https://docs.basho.com/riak/kv/2.2.0/learn/concepts/. |

|------------------|----------------------------------------------------------------------------------------------------------------|

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used with other Riak components, particularly tRiakConnection.</th>
</tr>
</thead>
</table>

**Related Scenario**

For a scenario in which tRiakClose is used, see Exporting data from a Riak bucket to a local file on page 3218.
tRiakConnection

Opens and reuses of the connection it creates to a Riak cluster.

**tRiakConnection Standard properties**

These properties are used to configure tRiakConnection running in the Standard Job framework.

The Standard tRiakConnection component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Nodes</th>
<th>Fill in the information required for a connection to a Riak cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>Host</strong>: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.</td>
</tr>
<tr>
<td></td>
<td><strong>Port</strong>: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.</td>
</tr>
<tr>
<td></td>
<td><strong>Riak path</strong>: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value <code>riak</code>.</td>
</tr>
<tr>
<td></td>
<td>One example of the URL for accessing a Riak node is <code>http://127.0.0.1:8098/riak</code>.</td>
</tr>
<tr>
<td></td>
<td>For more information about the concepts related to Riak, see <a href="https://docs.basho.com/riak/kv/2.2.0/learn/concepts/">https://docs.basho.com/riak/kv/2.2.0/learn/concepts/</a>.</td>
</tr>
</tbody>
</table>

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

*For further information about variables, see Talend Studio User Guide.*
Usage

| Usage rule | This component is generally used with other Riak components, particularly tRiakClose. |

Related scenario

For a scenario in which tRiakConnection is used, see Exporting data from a Riak bucket to a local file on page 3218.
tRiakInput

Extracts the desired data from a bucket in a Riak node so as to store or apply changes to the data. tRiakInput reads data from a Riak bucket and send data in the Talend flow.

**tRiakInput Standard properties**

These properties are used to configure tRiakInput running in the Standard Job framework.

The Standard tRiakInput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Description</th>
<th>Details</th>
</tr>
</thead>
</table>
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window. |
| **Use existing connection** | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

If you select the **Use an existing connection** check box, the Nodes table will not be available. |
| **Nodes** | Fill in the information required for a connection to a Riak cluster.

- **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.
- **Port**: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.
- **Riak path**: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value `riak`.

One example of the URL for accessing a Riak node is `http://127.0.0.1:8098/riak`. |
For more information about the concepts related to Riak, see [https://docs.basho.com/riak/kv/2.2.0/learn/concepts/](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).

### Bucket
Type in the name of the bucket from which you want to read data.

### Key
Type in the key which is associated with the data that you want to read.

### Output key to column
Select this check box and from the list select the desired column to which the keys will be output.

### Values column
Customize the columns to which the values will be output.

### Advanced settings

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

#### Global Variables

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).

### Usage

#### Usage rule
This component always needs an output link.

### Exporting data from a Riak bucket to a local file

This scenario applies only to [Talend products with Big Data](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).

The following scenario describes a Job which reads data from a Riak bucket and writes it into a local txt file.
**Prerequisites:** The Riak bucket from which you want to export data already exists. In this example, the data from the bucket *computer* will be exported and the bucket has already imported the following data:

<table>
<thead>
<tr>
<th>id</th>
<th>company</th>
<th>product</th>
<th>price</th>
<th>owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>001</td>
<td>Dell</td>
<td>Inspiron 15</td>
<td>299</td>
<td>Amanda</td>
</tr>
<tr>
<td>002</td>
<td>Dell</td>
<td>Inspiron 15R</td>
<td>549</td>
<td>Linda</td>
</tr>
<tr>
<td>003</td>
<td>HP</td>
<td>Pavilion 500-210qe</td>
<td>539</td>
<td>Marina</td>
</tr>
<tr>
<td>004</td>
<td>HP</td>
<td>Pavilion 500-075</td>
<td>599</td>
<td>Diana</td>
</tr>
</tbody>
</table>

**Dropping and linking components**

**Procedure**

1. Drop the following components from the Palette to the design workspace: `tRiakConnection`, `tRiakInput`, `tFileOutputDelimited`, and `tRiakClose`.
2. Connect `tRiakConnection` to `tRiakInput` using a Trigger > On Subjob Ok link.
3. Connect `tRiakInput` to `tFileOutputDelimited` using a Row > Main link.
4. Connect `tFileOutputDelimited` to `tRiakClose` using a Trigger > On Component Ok link.

**Configuring the components**

**Opening a connection to Riak**

**Procedure**

1. Double-click `tRiakConnection` to open its Basic settings view in the Component tab.
2. In the Nodes table, enter the information of a Riak cluster you want to connect to.
Exporting data from a Riak bucket to a local file

Procedure

1. Double-click tRiakInput to open its Basic settings view in the Component tab.

```
<table>
<thead>
<tr>
<th>Basic settings</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection</td>
</tr>
<tr>
<td>Use an existing connection</td>
</tr>
<tr>
<td>Bucket</td>
</tr>
<tr>
<td>Key</td>
</tr>
<tr>
<td>Key</td>
</tr>
<tr>
<td>Values</td>
</tr>
<tr>
<td>Value columns</td>
</tr>
<tr>
<td>Column</td>
</tr>
<tr>
<td>company</td>
</tr>
<tr>
<td>price</td>
</tr>
</tbody>
</table>
```

2. Click Edit schema to define the structure of exported data. In this example, three columns are defined: id, company, and price.

```
<table>
<thead>
<tr>
<th>Column</th>
<th>Db Column</th>
<th>Key</th>
<th>Type</th>
<th>N.</th>
<th>Date</th>
<th>L.</th>
<th>Pr.</th>
<th>D.</th>
<th>C.</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
<td>id</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>company</td>
<td>company</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>price</td>
<td>price</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>
```

3. Select the Use an existing connection check box and then select the connection you have configured earlier. In this example, it is tRiakConnection_1.

4. In the Bucket field, enter the name of the bucket from which the data will be exported, computer in this example.
Select the **Output key to column** check box, and select the desired column from the list. *id* is selected in this example.

In the **Value columns** table, click twice the **button and select company and price from the list respectively.**

### Writing data into a local file

**Procedure**

1. Double-click **tFileOutputDelimited** to open its **Basic settings** view in the **Component** tab.

![tFileOutputDelimited_1](image)

2. In the **File Name** field, enter the full path to the local file in which you want to store the exported data, *D:/Output/computer.txt* in this example.

3. Select the **Include Header** check box.

4. Leave other settings as they are.

### Closing the connection to Riak

**Procedure**

1. Double-click **tRiakClose** to open its **Basic settings** view in the **Component** tab.

2. Select the connection you want to close from the **Component List**, **tRiakConnection_1** in this example.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

3. Go to the local directory where the file is stored and check the exported data from the Riak bucket.
<table>
<thead>
<tr>
<th>id</th>
<th>company</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>003</td>
<td>HP</td>
<td>539</td>
</tr>
<tr>
<td>004</td>
<td>HP</td>
<td>599</td>
</tr>
<tr>
<td>001</td>
<td>Dell</td>
<td>299</td>
</tr>
<tr>
<td>002</td>
<td>Dell</td>
<td>549</td>
</tr>
</tbody>
</table>
tRiakKeyList

Retrieves a list of keys and iterates on it within a Riak bucket for analysis or development purposes.

**tRiakKeyList Standard properties**

These properties are used to configure tRiakKeyList running in the Standard Job framework.

The Standard tRiakKeyList component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes</td>
<td>Fill in the information required for a connection to a Riak cluster.</td>
</tr>
<tr>
<td>Host</td>
<td>enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.</td>
</tr>
<tr>
<td>Port</td>
<td>enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.</td>
</tr>
<tr>
<td>Riak path</td>
<td>enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.</td>
</tr>
<tr>
<td>One example of the URL for accessing a Riak node is <a href="http://127.0.0.1:8098/riak">http://127.0.0.1:8098/riak</a>. For more information about the concepts related to Riak, see <a href="https://docs.basho.com/riak/kv/2.2.0/learn/concepts/">https://docs.basho.com/riak/kv/2.2.0/learn/concepts/</a>.</td>
<td></td>
</tr>
<tr>
<td>Bucket</td>
<td>Type in the name of the bucket from which you want to retrieve all keys.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level.                                                                           |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>CURRENT_KEY: the current key. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable.</td>
</tr>
</tbody>
</table>
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

#### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as a standalone component.</th>
</tr>
</thead>
</table>

#### Related scenarios

No scenario is available for the Standard version of this component yet.
tRiakOutput

Receives data from the preceding component and writes data into or deletes data from a bucket in a Riak cluster.

**tRiakOutput Standard properties**

These properties are used to configure tRiakOutput running in the Standard Job framework.

The Standard tRiakOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
| | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
| | • **View schema**: choose this option to view the schema only.
| | • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
| | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
| **Built-In**: You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*.
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*.
| When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
| You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).
| **Use existing connection** | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.
| | If you select the **Use an existing connection** check box, the **Nodes** table will not be available. |
## Nodes

Fill in the information required for a connection to a Riak cluster.

- **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.
- **Port**: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.
- **Riak path**: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value `riak`.

One example of the URL for accessing a Riak node is `http://127.0.0.1:8098/riak`.

For more information about the concepts related to Riak, see [https://docs.basho.com/riak/kv/2.2.0/learn/concepts/](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).

## Bucket

Specify the name of the bucket to which you want to apply changes.

## Action on data

In the specified bucket, you can perform:

- **Upsert**: Insert data if they do not exist or update the existing data.
- **Delete**: Remove values associated with the specified key.

If you select `Delete` from the `Action on data` list, only the **Key column** list is available in the **Key area**.

## Auto generate the key

Select this check box to let the Riak system generate keys for the values automatically.

## Key column

Select one column from the list to write its data into the Riak bucket as keys. Note that the key must be unique across one bucket.

## Value columns

Customize the columns to write their data into the Riak bucket as values.

## Advanced settings

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

## Global Variables

### Global Variables

- **UPSERT_NB_LINE**: the number of rows inserted and updated. This is an After variable and it returns an integer.
- **DELETE_NB_LINE**: the number of rows deleted. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is used as an output component and it always needs an incoming link. |

Related scenarios

No scenario is available for the Standard version of this component yet.
## tRouteFault

Sends messages from a Data Integration Job to a Mediation Route and mark the message as fault.

### tRouteFault Standard properties

These properties are used to configure tRouteFault running in the Standard Job framework.

The Standard tRouteFault component belongs to the ESB family.

This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).

#### Basic settings

<table>
<thead>
<tr>
<th>Output Schema and Edit schema</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td>Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>

**Exchanging messages between a Job and a Route**

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to exchange messages between a Job and a Route using the tRouteInput and the tRouteFault component. To do this, a Job is created to receive the message from the Route and mark the message as fault. Then a Route is built to send the message to the Job and handle the fault message.

**Creating an Data Integration Job**

In this section, a Job named RouteCommunication_tRouteFault is built.
Arranging the flow of the message

About this task

Procedure

1. Drag and drop a tRouteInput and a tRouteFault from the Palette onto the design workspace.
2. Right-click the tRouteInput component, select Row > Main from the contextual menu and click the tRouteFault component.

Configuring how the message is processed

Procedure

1. Double-click the tRouteInput component to open its Basic settings view in the Component tab.
2. Click the three-dot button next to Edit Schema. In the schema dialog box, click the plus button to add a new line of String type and name it body. Click OK to close the dialog box.
3. In the **Simple Expression** field for the *body* element, enter "${in.body}" to get the body of the input message from the Route.

4. Double-click the **tRouteFault** component to display its **Basic settings** view in the **Component** tab.

5. Make sure that **tRouteFault** has one element *body*. Set its type to **Body**.

6. Press **Ctrl+S** to save your Job.

**Creating a Mediation Route**

In this section, we will create a Route to send a message to the Job and handle the fault message.

**Dropping and linking the components**

**About this task**

![Diagram of components](image)

**Procedure**

1. Drag and drop a **cTimer**, a **cSetBody**, a **cJavaDSLProcessor**, a **cTalendJob**, a **cOnException** and a **cProcessor** component from the **Palette** onto the design workspace.

2. Link the components with the **Row > Route** connection as shown above.

3. Label the components for better identification of their roles.

**Configuring the components**

**Procedure**

1. Double-click the **cTimer** component to open its **Basic settings** view in the **Component** tab.
2. Enter 1 in the **Repeat** field to trigger a message exchange one time.

3. Double-click the **cSetBody** component to display its **Basic settings** view in the **Component** tab.

4. Select **Simple** from the **Language** list and enter **Hello!** in the **Expression** field.

5. Double-click the **cJavaDSLProcessor** component to open its **Basic settings** view in the **Component** tab.

6. Enter `.handleFault()` in the **Code** box so that the fault message will be caught as an exception.

7. Double-click the **cTalendJob** component to display its **Basic settings** view in the **Component** tab.
8. Select Job `RouteCommunication_tRouteFault` from the repository to call the Job that is created in the previous section.

9. Double click the `cOnException` component to display its Basic settings view in the Component tab.

10. Click `[*]` to add a line to the Exceptions table, and enter `org.apache.camel.CamelException` in the Exception field to handle the exceptions.

11. Double-click the `cProcessor` component to display its Basic settings view in the Component tab.
12. Customize the code in the Code area to show the message body:

```java
System.out.println(exchange.getIn());
```

13. Press Ctrl+S to save your Route.

**Executing the Route**

Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

The message Hello! is sent from the Route to the Job and caught as exception:
[tRouteFault] connecting to socket on port 3783

Processed by failure processor: FallbackErrorProcessor[Channel[DelegateSync[local_project.troutefault_0_1.tRouteFault102511045b]]]

tRouteInput

Accepts messages in a Data Integration Job from a Mediation Route.

**tRouteInput Standard properties**

These properties are used to configure tRouteInput running in the Standard Job framework.

The Standard tRouteInput component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

| **Input Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the `Repository` type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to `Built-in` for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored.</td>
<td></td>
</tr>
</tbody>
</table>
| **Camel** | Enter the message parameters corresponding to the columns you defined in the schema dialog box via the **Edit schema** button using the Simple Expression Language.

For more information about the Simple Expression Language, see the site [http://camel.apache.org/simple.html](http://camel.apache.org/simple.html). |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable |

3236
and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component can be used as starter component and has an output. It is mandatory that a **tRouteInput** component is used in the Data Integration Job to be called by a Route using the **cTalendJob** component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.

For more information about how to use the **cTalendJob** component, see Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
| --- | --- |

<table>
<thead>
<tr>
<th>Limitation</th>
<th>The Job using a <strong>tRouteInput</strong> must be launched only within a Route using the <strong>cTalendJob</strong> component.</th>
</tr>
</thead>
</table>

### Exchanging messages between a Job and a Route

This scenario applies only to *Talend Open Studio for ESB*, *Talend Data Services Platform* and *Talend Data Fabric*.

This scenario describes how to accept messages from a Route using the **tRouteInput** component and send messages to a Route using the **tRouteOutput** component. To do this, we need to build a Job and a Route to call the Job using the **cTalendJob** component.

For more information about how to use the **cTalendJob** component, see Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Creating an Data Integration Job

In this section, we will build a Job named *RouteCommunication* to accept the message from a Route, change the message body and send the message back to the Route.

### Arranging the flow of the message

*About this task*
Procedure

1. Drag and drop a \texttt{tRouteInput}, a \texttt{tLogRow}, a \texttt{tReplace} and a \texttt{tRouteOutput} from the Palette onto the design workspace.
2. Link the components using the Row > Main connection as shown above.

Configuring how the message is processed

Procedure

1. Double-click the \texttt{tRouteInput} component to open its Basic settings view in the Component tab.

2. Click the three-dot button next to Edit Schema. In the schema dialog box, click the plus button to add a new line of String type and name it \textit{body}. Click OK to close the dialog box.

3. In the Simple Expression field for the \textit{body} element, enter "\texttt{$\{in.body\}}" to get the body of the input message from the Route.

4. The \texttt{tLogRow} component will monitor the message exchanges and does not need any configuration.

5. Double-click the \texttt{tReplace} component to open its Basic settings view in the Component tab.
6. Click **Sync columns** to retrieve the schema from the tLogRow. In the pop-up dialog box, click **Yes** to propagate the schema to the subsequent component.

Click [+] to add a row to the **Search/Replace** table. Enter **World** in the **Search** column and **Talend** in the **Replace with** column. Clear the **Whole word** check box.

7. Double-click the **tRouteOutput** component to display its **Basic settings** view in the **Component** tab.

8. Make sure that **tRouteOutput** has one element **body**. Set its type to **Body**.

9. Press **Ctrl+S** to save your Job.

**Creating a Mediation Route**

In this section, we will create a Route to send a message to the Job and receive the message sent back to the Route.
Dropping and linking the components

About this task

![Diagram of components]

Procedure

1. Drag and drop a **cTimer**, a **cSetBody**, a **cTalendJob**, and a **cLog** from the **Palette** onto the design workspace.
2. Link the components with the **Row > Route** connection as shown above.
3. Label the components for better identification of their roles.

Configuring the components

Procedure

1. Double-click the **cTimer** component to open its **Basic settings** view in the **Component** tab.

   ![cTimer settings]

   - In the **Repeat** field, enter **1** to generate the message exchange one time. Keep the default settings of the other options.

2. Double click the **cSetBody** component to display its **Basic settings** view in the **Component** tab.

   ![cSetBody settings]

   - Select **Simple** from the **Language** list and enter **Hello World!** in the **Expression** field.

3. Double-click the **cTalendJob** component to display its **Basic settings** view in the **Component** tab.
6. Select Job *RouteCommunication* from the repository.
7. The *cLog* component will monitor the message exchanges and does not need any configuration.
8. Press *Ctrl+S* to save your Route.

**Executing the Route**

Click the *Run* view to display it and click the *Run* button to launch the execution of your Route. You can also press *F6* to execute it. In the execution log you can see that the message *Hello World!* is sent to the Job. The message body is changed to *Hello Talend!* and sent back to the Route.
tRouteOutput

Sends messages from a Data Integration Job to a Mediation Route.

**tRouteOutput Standard properties**

These properties are used to configure tRouteOutput running in the Standard Job framework.

The Standard tRouteOutput component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s)*.

**Basic settings**

| Output Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the Repository file where Properties are stored.</td>
<td></td>
</tr>
<tr>

<td>Enter the message parameters corresponding to the columns you defined in the schema dialog box via the <strong>Edit schema</strong> button.</td>
</tr>
</tbody>
</table>
| Type | Select between:  
**Body**: Used to set the body of a Route, equals the code exchange.getOut().setBody(...).  
**Property**: Used to set the property of a Route, equals the code exchange.setProperty(name, value).  
**System**: Used to set the system property, equals the code System.setProperty(name, value).  
**Header**: Used the set the output header, equals the code exchange.getOut().setHeader(name, value). |
### Name

This column is used to set the name for the parameter when its type is either Property, System or Header. This column is ignored when the type is Body.

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

### Usage

| **Usage rule** | This component can be used as the end component and thus requires an input component. It is mandatory that a **tRouteInput** component is used in the Data Integration Job to be called by a Route using the **cTalendJob** component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in **Talend Runtime**. Instead it will only start when it gets called by the Route.  
For more information about how to use the **cTalendJob** component, see Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

| **Limitation** | The Job using a **tRouteOutput** must be launched only within a Route using the **cTalendJob** component. |

### Related scenario

For a scenario in which **tRouteOutput** is used, see Exchanging messages between a Job and a Route on page 3237.
tRowGenerator

Creates an input flow in a Job for testing purposes, in particular for boundary test sets.

tRowGenerator generates as many rows and fields as are required using random values taken from a list.

**tRowGenerator Standard properties**

These properties are used to configure tRowGenerator running in the Standard Job framework.

The Standard tRowGenerator component belongs to the Misc family.

The component in this framework is available in all Talend products.

**Basic settings**

| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.

**RowGenerator editor**

The editor allows you to define the columns and the nature of data to be generated. You can use predefined routines or type in the function to be used to generate the data specified.

Note that in a Storm Job, the value -1 in the **Number of rows for RowGenerator** field in the **RowGenerator editor** means to generate infinite rows of input data.
Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
| | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| | For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | The tRowGenerator Editor’s ease of use allows users without any Java knowledge to generate random data for test purposes. |

Defining the schema

First you need to define the structure of data to be generated.

- Add as many columns to your schema as needed, using the plus (+) button.
- Type in the names of the columns to be created in the Columns area and select the Key check box if required.
- Make sure you define then the nature of the data contained in the column, by selecting the Type in the list. According to the type you select, the list of Functions offered will differ. This information is therefore compulsory.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID_employees</td>
<td></td>
<td>int</td>
<td></td>
<td>sequence</td>
<td>2</td>
</tr>
<tr>
<td>First_Name</td>
<td></td>
<td>String</td>
<td></td>
<td>...</td>
<td>Phoebe H</td>
</tr>
<tr>
<td>Last_Name</td>
<td></td>
<td>String</td>
<td></td>
<td>lastName</td>
<td>Eisenhower</td>
</tr>
<tr>
<td>Hire_Date</td>
<td></td>
<td>Day</td>
<td></td>
<td>getRandomDate</td>
<td>2008-09-31</td>
</tr>
</tbody>
</table>

Number of Rows for RowGenerator: 10
• Some extra information, although not required, might be useful such as **Length**, **Precision** or **Comment**. You can also hide these columns, by clicking on the **Columns** drop-down button next to the toolbar, and unchecking the relevant entries on the list.

• In the **Function** area, you can select the predefined routine/function if one of them corresponds to your needs. You can also add to this list any routine you stored in the **Routine** area of the **Repository**. Or you can type in the function you want to use in the **Function** definition panel. Related topic: see *Talend Studio User Guide*.

• Click **Refresh** to have a preview of the data generated.

• Type in a number of rows to be generated. The more rows to be generated, the longer it’ll take to carry out the generation operation.

### Defining the function

Select the [...] under **Function** in the Schema definition panel in order to customize the function parameters.

• Select the **Function parameters** tab

• The **Parameter** area displays **Customized parameter** as function name (read-only)

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>customize par...</td>
<td>sub-(getRandomString(1, [&quot;Roger&quot;, &quot;Bill&quot;, &quot;Jimmy&quot;, &quot;Chris&quot;, &quot;George&quot;]))</td>
<td></td>
</tr>
</tbody>
</table>

• In the **Value** area, type in the Java function to be used to generate the data specified.

• Click on the **Preview** tab and click **Preview** to check out a sample of the data generated.

### Generating random java data

The following scenario creates a two-component Job, generating 50 rows structured as follows: a randomly picked-up ID in a 1-to-3 range, a random ascii First Name and Last Name generation and a random date taken in a defined range.

• Drop a **tRowGenerator** and a **tLogRow** component from the **Palette** to the design workspace.

• Right-click **tRowGenerator** and select **Row** > **Main**. Drag this main row link onto the **tLogRow** component and release when the plug symbol displays.

• Double click **tRowGenerator** to open the Editor.

• Define the fields to be generated.
The random ID column is of integer type, the First and Last names are of string type and the Date is of date type.

In the Function list, select the relevant function or set on the three dots for custom function.

On the Function parameters tab, define the Values to be randomly picked up.

First_Name and Last_Name columns are to be generated using the getAsciiRandomString function that is predefined in the system routines. By default the length defined is 6 characters long. You can change this if need be.

The Date column calls the predefined getRandomDate function. You can edit the parameter values in the Function parameters tab.

Set the Number of Rows to be generated to 50.

Click OK to validate the setting.

Double click tLogRow to view the Basic settings. The default setting is retained for this Job.

Press F6 to run the Job.

The 50 rows are generated following the setting defined in the tRowGenerator editor and the output is displayed in the Run console.
tRSSInput

Reads RSS-Feeds using URLs. tRSSInput makes it possible to keep track of blog entries on websites to gather and organize information for quick and easy access.

**tRSSInput Standard properties**

These properties are used to configure tRSSInput running in the Standard Job framework.

The Standard tRSSInput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The tRSSInput component has a read-only schema that is made of four columns: TITLE, DESCRIPTION, PUBDATE, and Link.</td>
</tr>
<tr>
<td>RSS URL</td>
<td>Enter the URL for the RSS_Feed to read.</td>
</tr>
<tr>
<td>Read articles from</td>
<td>If selected, tRSSInput reads articles on the RSS_Feed from the date set through the three-dot […] button next to the date time field.</td>
</tr>
<tr>
<td>Max number of articles</td>
<td>If selected, tRSSInput reads as many articles as the number entered in the max amount field.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE:</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td>NB_LINE:</td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is generally used as an input component. It requires an output component.</th>
</tr>
</thead>
</table>

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Fetching frequently updated blog entries.

This two-component scenario aims at retrieving frequently updated blog entries from a Talend local news RSS feed using the tRSSInput component.

Procedure

1. Drop the following components from the Palette onto the design workspace: tRSSInput and tLogRow.
2. Right-click to connect them using a Row > Main link.
3. In the design workspace, select tRSSInput, and click the Component tab to define the basic settings for tRSSInput.
4. Enter the URL for the RSS_Feed to access. In this scenario, tRSSInput links to the Talend RSS_Feed: http://feeds.feedburner.com/Talend.
5. Select/clear the other check boxes as required. In this scenario, we want to display the information about two articles dated from July 20, 2008.
6. In the design workspace, select tLogRow and click the Component tab to define its basic settings. For more information about tLogRow properties, see tLogRow Standard properties on page 1971.
7. Save the Job and press F6 to execute it.

```

#1. tLogRow_1
  key                     value
  TITLE     Welcoming Jean-Luc Solans
  DESCRIPTION Jean-Luc Solans joins Talend as VP of Strategy and Business
  PUBDATE   24 Jul 2008 19:40:11 GMT
  LINK      http://feeds.feedburner.com/~r/Talend/~3/344920575/

#2. tLogRow_1
  key                     value
  TITLE     Talend Open Profiler gets rave reviews
  DESCRIPTION An interview and a product review of Talend Open Profiler.
  PUBDATE   23 Jul 2008 21:12:53 GMT
  LINK      http://feeds.feedburner.com/~r/Talend/~3/343928056/

Job RSSInput ended at 15:17 07/08/2008. [exit code=0]
```

The `tRSSInput` component accessed the RSS feed of **Talend** website on your behalf and organized the information for you.

Two blog entries are displayed on the console. Each entry has its own title, description, publication date, and the corresponding RSS feed URL address. Blogs show the last entry first, and you can scroll down to read earlier entries.
tRSSOutput

Creates and writes XML files that hold RSS or Atom feeds.

**tRSSOutput Standard properties**

These properties are used to configure tRSSOutput running in the Standard Job framework.

The Standard tRSSOutput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>File name</strong></th>
<th>Name or path to the XML file to be processed and/or the variable to be used. For further information about how to define and use a variable in a Job, see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Encoding</strong></td>
<td>Select an encoding type from the list, or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows to the end of the file.</td>
</tr>
<tr>
<td><strong>Mode</strong></td>
<td>Select between <strong>RSS</strong> or <strong>ATOM</strong> according to the feed you want to generate.</td>
</tr>
</tbody>
</table>

**Channel (in RSS mode)**

- **Title**: Enter a meaningful title.
- **Description**: Enter a description that you think will describe your content.
- **Publication date**: Enter the relevant date.
- **Link**: Enter the relevant URL.

**Note:**
The information to be typed in here concerns your entire input data, site etc, rather than a particular item.

**Feed (in ATOM mode)**

- **Title**: Enter a meaningful title.
- **Link**: Enter the relevant URL.
- **Id**: Enter the valid URL corresponding to the **Link**.
- **Update date**: Enter the relevant date.
- **Author name**: Enter the relevant name.

**Optionnal Channel Elements**

Click the [+] button below the table to add new lines and enter the information relative to the RSS flow metadata:

- **Element Name**: name of the metadata.
- **Element Value**: content of the metadata.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next
component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

By default, the schema of **tRSSOutput** is made of five read-only columns: `id`, `title`, `link`, `updated`, and `summary`. You can add new columns or click **Syn columns** to retrieve the schema structure from the preceding component.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

**Usage**

| Usage rule | This component must be linked to an input or intermediary component. |

**Creating an RSS flow and storing files on an FTP server**

In this scenario we:
• create an RSS flow for files that you would like to share with other people, and
• store the complete files on an FTP server.

This scenario writes an RSS feed XML file about a MySQL table holding information about books. It adds links to the files stored on an FTP server in case users want to have access to the complete files.

**Dropping and linking components**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: tMysqlInput, tRSSOutput, and tFTPPut.
2. Right-click tMysqlInput and connect it to tRSSOutput using a Row > Main link.
3. Right-click tMysqlInput and connect it to tFTPPut using a Trigger > OnSubjobOk link.

![Diagram showing the flow of components](image)

**Defining the data source**

**Procedure**

1. In the design workspace, select tMysqlInput, and click the Component tab to define the basic settings for tMysqlInput.
### Creating an RSS flow

**Procedure**

1. In the design workspace, select **tRSSOutput**, and click the **Component** view to define the basic settings for **tRSSOutput**.

2. Set the **Property type** to **Repository** and click the three-dots button [...] to select the relevant DB entry from the list. The connection details along with the schema get filled in automatically.

3. In the **Table Name** field, either type your table name or click the three dots button [...] and select your table name from the list. In this scenario, the Mysql input table is called "rss_talend" and the schema is made up of four columns, **TITLE**, **Description**, **PUBDATE**, and **LINK**.

4. In the **Query** field, enter your DB query paying particular attention to properly sequence the fields in order to match the schema definition, or click **Guess Query**.

```sql
"SELECT rss_talend.TITLE, rss_talend.DESCRIPTION, rss_talend.PUBDATE, rss_talend.LINK FROM rss_talend"
```
2. In the **File name** field, use the by default file name and path, or browse to set your own for the output XML file.

3. Select the encoding type on the **Encoding Type** list.

4. In the **Mode** area, select **RSS**.

5. In the **Channel** panel, enter a title, a description, a publication date, and a link to define your input data as a whole.

6. Click **Edit Schema** to modify the schema if necessary.

   **Note:**
   
   You can click **Sync columns** to retrieve the generated schema from the preceding component.

7. Save your Job and press **F6** to execute this first part.
The tRSSOutput component created an output RSS flow in an XML format for the defined files.

Writing the complete files to an FTP server

About this task
To store the complete files on an FTP server:

Procedure
1. In the design workspace, select FTPPut, and click the Component tab to define the basic settings for tFTPPut.
2. Enter the host name and the port number in their corresponding fields.
3. Enter your connection details in the corresponding Username and Password fields.
4. Browse to the local directory, or enter it manually in the Local directory field.
5. Enter the details of the remote server directory.
6. Select the transfer mode from the Transfer mode list.
7. On the Files panel, click on the plus button to add new lines and fill in the filemasks of all files to be copied onto the remote directory. In this scenario, the files to be saved on the FTP server are all text files.
8. Save your Job and press F6 to execute it.

Files defined in the Filemask are copied on the remote server.

Creating an RSS flow that contains metadata

This scenario describes a two-component Job that creates an RSS flow that holds metadata and then redirects the obtained information in an XML file of the output RSS flow.

Dropping and linking components

Procedure
1. Drop tRSSInput and tRSSOutput from the Palette to the design workspace.
2. Connect the two components together using a Row > Main link.

Configuring the components

Procedure
1. Double-click tRSSInput to open its Basic settings view and define the component properties.
2. Enter the URL for the RSS_Feed to access. In this scenario, **tRSSInput** links to the **Talend RSS_Feed**: [http://feeds.feedburner.com/Talend](http://feeds.feedburner.com/Talend).

3. In the design workspace, double-click **tRSSOutput** to display its **Basic settings** view and define the component properties.

4. In the **File name** field, use the by default file name and path, or browse to set your own for the output XML file.

5. Select the encoding type on the **Encoding Type** list.

6. In the **Mode** area, select **RSS**.

7. In the **Channel** panel, enter a title, a description, a publication date and a link to define your input data as a whole.

8. In the **Optional Channel Element**, define the RSS flow metadata. In this example, the flow has two metadata: **copyright**, which value is **tos**, and **language** which value is **en_us**.

9. Click **Edit Schema** to modify the schema if necessary.
**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

   ![Image of XML code]

   The defined files are copied in the output XML file and the metadata display under the `<channel>` node above the information about the RSS flow.

**Creating an ATOM feed XML file**

This scenario describes a two component Job that generates data and writes them in an ATOM feed XML file.
Dropping and linking components

Procedure

1. Drop the following components from the **Palette** onto the design workspace: **tFixedFlowInput** of the **Misc** component group and **tRSSOutput** of the **Internet** component group.

2. Right-click **tFixedFlowInput** and connect it to **tRSSOutput** using a **Row Main** link.

3. When asked whether you want to pass on the schema of **tRSSOutput** to **tFixedFlowInput**, click **Yes**.

Configuring the components

Procedure

1. In the design workspace, double-click **tFixedFlowInput** to display its corresponding **Component** view and define its basic settings.

2. In the **Number of rows** field, leave the default setting to **1** to only generate one line of data.

3. In the **Mode** area, leave the **Use Single Table** option selected and fill in the **Values** table. Note that the **Column** field of the **Values** table is filled in by the columns of the schema defined in the component.

4. In the **Value** field of the **Values** table, type in the data you want to be sent to the following component.

5. In the design workspace, double-click **tRSSOutput** to display its corresponding **Component** view and define its basic settings.
6. Click the [...] button next to the **File Name** field to set the output XML file directory and name.

7. In the **Mode** area, select **ATOM** to generate an ATOM feed XML file.

**Warning:**

As the ATOM feed format is strict, some default information is required to create the XML file. So, the schema **tRSSOutput** contains default columns that will contain those information. Those default columns are greyed out to indicate that they must not be modified. If you choose to modify the schema of the component, the ATOM XML file created will not be valid.

8. In the **Feed** area, enter a title, link, id, update date, author name to define your input data as a whole.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.
The `tRSSOutput` component creates an output ATOM flow in an XML format.
**tRunJob**

Manages complex Job systems which need to execute one Job after another.

tRunJob executes the Job called in the component’s properties, in the frame of the context defined.

**tRunJob Standard properties**

These properties are used to configure tRunJob running in the Standard Job framework.

The Standard tRunJob component belongs to the System and the Orchestration families.

The component in this framework is available in all Talend products.

**Warning:**

The tRunJob component is supported with limitations, which means that only S4 (Minor) support cases are accepted and no patches are provided. If you use tRunJob within Data Services and Routes (with cTalendJob), support is provided on a "best effort" basis only. In most cases, there are class loading issues which can sometimes be resolved but not always.

This is because tRunJob is not designed to work in a Service/Route style (ESB) deployment, so regular support is not provided if you decide to use it, even though it may work in many cases. If you used tRunJob in the past, it is recommended to change your Job Design to use Joblets instead.

For DI and non-ESB use cases, it is still a valuable component and has support.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Copy Child Job Schema</td>
<td>Click to fetch the child Job schema.</td>
</tr>
<tr>
<td>-------------------------------</td>
<td>-------------------------------------</td>
</tr>
<tr>
<td><strong>Use dynamic job</strong></td>
<td>Select this check box to allow multiple Jobs to be called and processed. When this option is enabled, only the latest version of the Jobs can be called and processed. An independent process will be used to run the subJob. The <strong>Context</strong> and the <strong>Use an independent process to run subJob</strong> options disappear.</td>
</tr>
<tr>
<td><strong>Warning:</strong> The <strong>Use dynamic job</strong> option is not compatible with the Jobserver cache. Therefore, the execution may fail if you run a Job that contains <code>tRunjob</code> with this check box selected in Talend Administration Center.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is incompatible with the <strong>Use or register a shared DB Connection</strong> option of database connection components. When <code>tRunJob</code> works together with a database connection component, enabling both options will cause your Job to fail.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is not supported within ESB Routes or Data Services.</td>
<td></td>
</tr>
<tr>
<td><strong>Context job</strong></td>
<td>This field is visible only when the <strong>Use dynamic job</strong> option is selected. Enter the name of the Job that you want to call from the list of Jobs selected.</td>
</tr>
<tr>
<td><strong>Job</strong></td>
<td>Select the Job to be called in and processed. Make sure you already executed once the Job called, beforehand, in order to ensure a smooth run through <code>tRunJob</code>.</td>
</tr>
<tr>
<td><strong>Version</strong></td>
<td>Select the child Job version that you want to use.</td>
</tr>
<tr>
<td><strong>Context</strong></td>
<td>If you defined contexts and variables for the Job to be run by the <code>tRunJob</code>, select the applicable context entry on the list.</td>
</tr>
<tr>
<td><strong>Use an independent process to run subJob</strong></td>
<td>Select this check box to use an independent process to run the subJob. This helps in solving issues related to memory limits.</td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is not compatible with the Jobserver cache. Therefore, the execution may fail if you run a Job that contains <code>tRunjob</code> with this check box selected in Talend Administration Center.</td>
<td></td>
</tr>
<tr>
<td><strong>Warning:</strong> This option is incompatible with the <strong>Use or register a shared DB Connection</strong> option of database connection components. When <code>tRunJob</code> works together with a database connection component, enabling both options will cause your Job to fail.</td>
<td></td>
</tr>
<tr>
<td><strong>Die on child error</strong></td>
<td>Clear this check box to execute the parent Job even though there is an error when executing the child Job.</td>
</tr>
</tbody>
</table>
**Transmit whole context**

Select this check box to get all the context variables from the parent Job. Deselect it to get all the context variables from the child Job.

If this check box is selected when the parent and child Jobs have the same context variables defined:

- variable values for the parent Job will be used during the child Job execution if no relevant values are defined in the *Context Param* table.
- otherwise, values defined in the *Context Param* table will be used during the child Job execution.

**Context Param**

You can change the value of selected context parameters. Click the ![+] button to add the parameters defined in the *Context* tab of the child Job. For more information on context parameters, see *Talend Studio User Guide*.

The values defined here will be used during the child Job execution even if *Transmit whole context* is selected.

### Advanced settings

**Propagate the child result to the output schema**

Select this check box to propagate the output data stored in the buffer memory via the *tBufferOutput* component in the child Job to the output component in the parent Job.

This property takes effect only when there is data coming from an input component such as *tFixedFlowInput*.

This check box is cleared by default. It is invisible when the *Use dynamic job* or *Use an independent process to run subJob* check box is selected.

**Print Parameters**

Select this check box to display the internal and external parameters in the *Console*.

**tStatCatcher Statistics**

Select this check box to gather the processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box.

- **CHILD_RETURN_CODE**: the return code of a child Job. This is an After variable and it returns an integer.

- **CHILD_EXCEPTION_STACKTRACE**: the exception stack trace from a child Job. This is an After variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press *Ctrl + Space* to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as a standalone Job or can help clarifying complex Job by avoiding having too many subjobs all together in one Job.</th>
</tr>
</thead>
</table>

**Connections**

<table>
<thead>
<tr>
<th>Outgoing links (from this component to another):</th>
<th>Row: Main.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Trigger</strong>: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error</td>
<td></td>
</tr>
<tr>
<td>Incoming links (from one component to this one):</td>
<td>Row: Main; Reject; Iterate.</td>
</tr>
<tr>
<td><strong>Trigger</strong>: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.</td>
<td></td>
</tr>
</tbody>
</table>

For further information regarding connections, see Talend Studio User Guide.

**Calling a Job and passing the parameter needed to the called Job**

This scenario describes a two-component Job named ParentJob that calls another Job named ChildJob to display the content of files specified in the ParentJob on the Run console.
Setting up the child Job

Procedure

1. Create a new Job ChildJob and add a `tFileInputDelimited` component and a `tLogRow` component to it.
2. Connect the `tFileInputDelimited` component to the `tLogRow` component using a Row > Main link.
3. Double-click the `tFileInputDelimited` component to open its Basic settings view.
4. Click in the File Name field and then press F5 to open the New Context Parameter dialog box and configure the context variable.
5. In the Name field, enter a name for this new context variable, `FilePath` in this example.
6. In the Default value field, enter the full path to the default input file.
7. Click Finish to validate the context parameter setup and fill the File Name field with the context variable.
   You can also create or edit a context parameter in the Context tab view beneath the design workspace. For more information, see Talend Studio User Guide.
8. Click the [...] button next to Edit schema to open the Schema dialog box where you can configure the schema manually.
9. In the dialog box, click the [+] button to add columns and name them according to the input file structure.

   In this example, this component will actually read files defined in the parent Job, and these files contain up to five columns. Therefore, add five string type columns and name them Column1, Column2, Column3, Column4, and Column5 respectively, and then click OK to validate the schema configuration and close the Schema dialog box.

10. Double-click the **tLogRow** component and on its **Basic settings** view, select the **Table** option to view displayed content in table cells.

### Setting up the parent Job

**Procedure**

1. Create a new Job **ParentJob** and add a **tFileList** component and a **tRunJob** component to it.

2. Connect the **tFileList** component to the **tRunJob** component using a **Row > Iterate** link.

3. Double-click the **tFileList** component to open its **Basic settings** view.

4. In the **Directory** field, specify the path to the directory that holds the files to be processed, or click the [...] button next to the field to browse to the directory.

   In this example, the directory is D:/tRunJob_Input_Files that holds three delimited files with up to five columns.

5. In the **FileList Type** list, select **Files**.

6. Select the **Use Glob Expressions as Filemask** check box, and then click the [+] button to add a line in the **Files** area and define a filter to match files. In this example, enter "*.csv" to retrieve all delimited files.

7. Double-click the **tRunJob** component to display its **Basic settings** view.
8. Click the [...] button next to the Job field and in the pop-up dialog box, select the child Job you want to execute and click OK to close the dialog box. The name of the selected Job appears in the Job field.

9. In the Context Param area, click the [+] button to add a line and define the context parameter. The only context parameter defined in the child Job, named FilePath, appears in the Parameters cell.

10. Click in the Values cell, press Ctrl+Space on your keyboard to access the list of context variables, and select tFileList_1.CURRENT_FILEPATH.

   The corresponding context variable ((String)globalMap.get("tFileList_1_CURRENT_FILEPATH")) appears in the Values cell.

   For more information on context variables, see Talend Studio User Guide.

**Executing the parent Job**

**Procedure**

1. Press Ctrl+S to save your Jobs.
2. Press F6 to execute the parent Job.
The parent Job calls the child Job, which reads the files defined in the parent Job, and the content of the files is displayed on the Run console.

**Running a list of child Jobs dynamically**

This scenario describes a Job that calls two child Jobs dynamically. When called from the parent Job, each of these simple child Jobs displays a message on the console.

**Setting up the child Jobs**

**Procedure**

1. Create a new Job named ChildJob1, and add a `tFixedFlowInput` component and a `tLogRow` component to it.

2. Connect the `tFixedFlowInput` component to the `tLogRow` component using a Row > Main connection.

3. Double-click the `tFixedFlowInput` component to open its Basic settings view.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema of the input data by adding one column Message of String type. When done, click OK to close the dialog box and click Yes when prompted to propagate the schema to the next component.

5. In the Mode area, select Use Inline Content(delimited file) and enter the message you want to show on the console in the Content field, Hello World! in this example.

6. Double-click the tLogRow component and on its Basic settings view, select the Table mode to display the execution result in table cells.

7. Create copy of this Job and name it ChildJob2, and enter another message in the Content field of the tFixedFlowInput component, Hello Talend! in this example.

**Setting up the parent Job**

**Procedure**

1. Create a new Job named ParentJob and add a tFixedFlowInput component, a tFlowToIterate component, and a tRunJob component to it.

2. Connect the tFixedFlowInput component to the tFlowToIterate component using a Row > Main connection and the tFlowToIterate component to the tRunJob component using a Row > Iterate connection.

3. Double-click the tFixedFlowInput component to open its Basic settings view.

4. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema of the input data by adding one column JobName of String type. When done, click OK to close the dialog box.

5. In the Mode area, select the Use Inline Content(delimited file) option and specify the names of the child Jobs to call from the parent Job in the Content field.
6. Double-click the **tRunJob** component to open its **Basic settings** view.

7. Select the **Use dynamic job** check box and in the **Context job** field displayed, press **Ctrl+Space** and from the list of variables select the iterative global variable created by the **tFlowToIterate** component, `tFlowToIterate_1.JobName` in this example. The **Context job** field is then filled with `((String)globalMap.get("row1.JobName"))`. Upon each iteration, this variable will be resolved as the name of the Job to be called.

8. Click the [...] button next to the **Job** field and in the **Select Job** dialog box, select all the Jobs you want to run and click **OK** to close the dialog box. In this example, they are **ChildJob1** and **ChildJob2**.

### Executing the parent Job to run the child Jobs dynamically

**Procedure**

1. Save your child Jobs and parent Job.
2. Press **F6** or click the **Run** button on the Run console to execute the Job.
As shown above, the child Jobs are called one after another and messages specified in the child Jobs are displayed on the console.

Propagating the buffered output data from the child Job to the parent Job

In this scenario, a three-component Job calls a two-component child Job and displays the buffered output data of the child Job, instead of the data from the input flow of the parent Job, on the console.

Setting up the child Job

About this task

Procedure

1. Create a Job named child, and add two components by typing their names on the design workspace or dropping them from the Palette to the design workspace:
   - a tFixedFlowInput, to generate a message
   - a tBufferOutput, to store the generated message in the buffer memory
2. Connect the tFixedFlowInput component to the tBufferOutput component using a Row > Main connection.
3. Double-click the tFixedFlowInput component to open its Basic settings view.
4. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.

When done, click OK to validate the changes and then click Yes in the pop-up Propagate dialog box to propagate the schema to the next component.

5. In the Mode area, select Use Single Table option, and define the corresponding value for the message column in the Values table. In this example, the value is "message from the child job".

Setting up the parent Job

About this task

Procedure

1. Create a Job, and add three components by typing their names on the design workspace or dropping them from the Palette to the design workspace:
   - a tFixedFlowInput, to generate a message
   - a tRunJob, to call the Job named child

2. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.

When done, click OK to validate the changes and then click Yes in the pop-up Propagate dialog box to propagate the schema to the next component.

3. In the Mode area, select Use Single Table option, and define the corresponding value for the message column in the Values table. In this example, the value is "message from the child job".
- a RunJob, to display the execution result on the console

2. Connect the FixedFlowInput component to the RunJob component and the RunJob component to the LogRow component using the Row > Main connections.

3. Double-click the FixedFlowInput component to open its Basic settings view.

4. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.

When done, click OK to validate the changes.

5. In the Mode area, select the Use Single Table option, and define the corresponding value for the message column in the Values table. In this example, the value is "message from the parent job".

6. Click the RunJob component and then click the Component tab to open its Basic settings view.
7. Click the **Sync columns** button and then click **Yes** in the pop-up **Propagate** dialog box to retrieve the schema from the preceding component.

8. Click the [...] button next to the **Job** field to open the **Repository Content** dialog box.

In the **Repository Content** dialog box, select the Job named **child** and then click **OK** to close the dialog box.

9. In the **Advanced settings** view of the **tRunJob** component, select the **Propagate the child result to the output schema** check box. With this check box selected, the buffered output of the child Job will be propagated to the output component.

### Executing the parent Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click the **Run** button on the **Run** console to execute the Job.
The child Job is called and the message specified in the child Job, rather than the message defined in the parent Job, is displayed on the console.
tS3BucketCreate

Creates a bucket on Amazon S3.

"Bucket" is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketCreate Standard properties**

These properties are used to configure tS3BucketCreate running in the Standard Job framework. The Standard tS3BucketCreate component belongs to the Cloud family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| Assume role              | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  - Role ARN: the Amazon Resource Name (ARN) of the role to assume.  
  - Role session name: an identifier for the assumed role session.  
  - Session duration (minutes): the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see AssumeRole. |
<p>| Region                   | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints. |</p>
<table>
<thead>
<tr>
<th>Bucket</th>
<th>Name of the bucket, namely the top level folder, to create.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Config client</th>
<th>Select this check box to configure client parameters.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Client parameter</strong>: select client parameters from the list.</td>
<td></td>
</tr>
<tr>
<td><strong>Value</strong>: enter the parameter value.</td>
<td></td>
</tr>
<tr>
<td>Not available when Use existing connection is selected.</td>
<td></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>STS Endpoint</th>
<th>Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.</th>
</tr>
</thead>
<tbody>
<tr>
<td>This check box is available only when the Assume role check box is selected.</td>
<td></td>
</tr>
</tbody>
</table>

| tStatCatcher Statistics                      | Select this check box to collect log data at the component level. |

**Global Variables**

| ERROR_MESSAGE                               | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used alone or with other S3 components, e.g. tS3BucketExist.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenario

For `tS3BucketCreate` related scenarios, see *Verifying the absence of a bucket, creating it and listing all the S3 buckets* on page 3286.
tS3BucketDelete

Deletes an empty bucket from Amazon S3.

"Bucket" is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketDelete Standard properties**

These properties are used to configure tS3BucketDelete running in the Standard Job framework.

The Standard tS3BucketDelete component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| Assume role | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  • Role ARN: the Amazon Resource Name (ARN) of the role to assume.  
  • Role session name: an identifier for the assumed role session.  
  • Session duration (minutes): the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see AssumeRole. |
| Region | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see Regions and Endpoints. |
**Bucket**  
Name of the bucket, namely the top level folder, to delete.

**Die on error**  
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**Config client**  
Select this check box to configure client parameters.  
**Client parameter:** select client parameters from the list.  
**Value:** enter the parameter value.  
Not available when Use existing connection is selected.

**STS Endpoint**  
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.  
This check box is available only when the Assume role check box is selected.

**tStatCatcher Statistics**  
Select this check box to collect log data at the component level.

### Global Variables

**ERROR_MESSAGE**  
The error message generated by the component when an error occurs. This is an After variable and it returns a string.  
This variable functions only if the Die on error check box is selected.

### Usage

**Usage rule**  
This component can be used alone or with other S3 components, e.g. tS3BucketList.

**Dynamic settings**  
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
**Related scenario**

For **tS3BucketDelete** related scenarios, see *Verifying the absence of a bucket, creating it and listing all the S3 buckets* on page 3286.
tS3BucketExist

Verifies if the specified bucket exists on Amazon S3.

“Bucket” is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketExist Standard properties**

These properties are used to configure tS3BucketExist running in the Standard Job framework.

The Standard tS3BucketExist component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| Assume role             | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  • Role ARN: the Amazon Resource Name (ARN) of the role to assume.  
  • Role session name: an identifier for the assumed role session.  
  • Session duration (minutes): the duration (in minutes) for which we want to have the assumed role session to be active.  
For more information on assuming roles, see AssumeRole. |
| Region                  | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see Regions and Endpoints. |
**name**: tS3BucketExist

**Bucket**
Name of the bucket, namely the top level folder, on the S3 server.

**Die on error**
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**Config client**
Select this check box to configure client parameters.

- **Client parameter**: select client parameters from the list.
- **Value**: enter the parameter value.

Not available when **Use existing connection** is selected.

**STS Endpoint**
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

### Global Variables

- **BUCKET_EXIST**
The existence of a specified bucket. This is a Flow variable and it returns a boolean.

- **BUCKET_NAME**
The name of a specified bucket. This is an After variable and it returns a string.

- **ERROR_MESSAGE**
The error message generated by the component when an error occurs. This is an After variable and it returns a string.

This variable functions only if the **Die on error** check box is selected.

### Usage

**Usage rule**
This component is usually used with other S3 components, e.g. tS3BucketCreate.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic...
Verifying the absence of a bucket, creating it and listing all the S3 buckets

In this scenario, `tS3BucketExist` is used to verify the absence of a bucket, `tS3BucketCreate` to create that bucket upon confirmation, and `tS3BucketList` to list all the buckets on Amazon S3.

**Linking the components**

**Procedure**

1. Drop `tS3Connection`, `tS3BucketExist`, `tS3BucketCreate`, `tS3BucketList`, `tIterateToFlow` and `tLogRow` onto the workspace.
2. Link `tS3Connection` to `tS3BucketExist` using the `OnSubjobOk` trigger.
3. Link `tS3BucketExist` to `tS3BucketCreate` using the `Run if` trigger.
4. Link `tS3BucketCreate` to `tS3BucketList` using the `OnSubjobOk` trigger.
5. Link `tS3BucketList` to `tIterateToFlow` using the `Row > Iterate` connection.
6. Link `tIterateToFlow` to `tLogRow` using the `Row > Main` connection.

**Configuring the components**

**Procedure**

1. Double-click `tS3Connection` to open its `Basic settings` view.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials.

3. Double-click **tS3BucketExist** to open its **Basic settings** view.

4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** field, enter the bucket name to check if it exists.

6. Double-click the **If** link to define the condition.

7. In the **Condition** box, enter the expression:

   ```java
   !((Boolean)globalMap.get("tS3BucketExist_1_BUCKET_EXIST"))
   ```

   This way, the rest of the Job will be executed if the specified bucket does not exist.

8. Double-click **tS3BucketCreate** to open its **Basic settings** view.

   Select the **Use existing connection** check box to reuse the connection.

   In the **Bucket** field, enter the bucket name to create.

9. Double-click **tS3BucketList** to open its **Basic settings** view.
Select the **Use existing connection** check box to reuse the connection.

10. Double-click **tIterateToFlow** to open its **Basic settings** view.

11. Click **Edit schema** to open the schema editor.

![Schema of tIterateToFlow_1 dialog box](image)

Click the [+] button to add one column, namely **bucket_list** of the String type. Click **Ok** to validate the setup and close the schema editor.

12. In the Mapping area, press **Ctrl + Space** in the Value field to choose the variable **tS3BucketList_1_CURRENT_BUCKET_NAME**.

13. Double-click **tLogRow** to open its **Basic settings** view.

![Basic settings dialog box](image)

Select **Table (print values in cells of a table)** for a better display of the results.
Executing the Job

Procedure

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```
[statistics] connecting to socket on port 3661
[statistics] connected

__LogRow_1__
bucket_list
movies_andy
songs_andy

[statistics] disconnected
```

As shown above, the bucket is created and all the buckets are listed.

3. Go to the S3 web console:

```
[Create Bucket] [Actions]

All Buckets

<table>
<thead>
<tr>
<th>Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>movies_andy</td>
</tr>
<tr>
<td>songs_andy</td>
</tr>
</tbody>
</table>
```

As shown above, the bucket has been created on the S3 server.

4. Refresh the S3 Browser client:

```
[New bucket] [Path: /]

movies_andy
songs_andy

File
action_movie.json
```

This shows that the S3 Create action was performed successfully.
tS3BucketList

Lists all the buckets on Amazon S3.

“Bucket” is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketList Standard properties**

These properties are used to configure tS3BucketList running in the Standard Job framework.

The Standard tS3BucketList component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

Related scenario

For `tS3BucketList` related scenarios, see Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3286.
**tS3Close**

Shuts down a connection to Amazon S3, thus releasing the network resources.

**tS3Close Standard properties**

These properties are used to configure tS3Close running in the Standard Job framework.

The Standard tS3Close component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

| Component List | List of connection components. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | As an end component, this component is to be used along with other S3 components, e.g. tS3Connection. |

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenario

For **tS3Close** related scenarios, see [Listing files with the same prefix from a bucket](#) on page 3317.
tS3Connection

Establishes a connection to Amazon S3 to store and retrieve data.

**tS3Connection Standard properties**

These properties are used to configure tS3Connection running in the Standard Job framework.

The Standard tS3Connection component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>

</tbody>
</table>
| **Assume role**              | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  - **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.  
  - **Role session name**: an identifier for the assumed role session.  
  - **Session duration (minutes)**: the duration (in minutes) for which we want to have the assumed role session to be active. For more information on assuming roles, see AssumeRole. |
| **Region**                   | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. 'us-east-1') in the list. For more information about the AWS Region, see Regions and Endpoints. |
| **Encrypt**                  | Select this check box and from the Key type drop-down list displayed, select one of the following three options for encrypting the data on the client-side before sending to Amazon S3. For more information, see Protecting Data Using Client-Side Encryption.  
  - **KMS-managed customer master key**: use a KMS-managed customer master key (CMK) for the client-side encryption. |
data encryption. In the **Key** field, you need to specify the AWS KMS customer master key ID (CMK ID).

- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **AES**.
  - **Encoding**: select the encoding type associated with the key from the list, either **Base64** or **X509**.
  - **Key** or **Key file**: specify the key or the path to the file that stores the key.

- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named **RSA**.
  - **Public key file**: specify the path to the public key file.
  - **Private key file**: specify the path to the private key file.

**Dynamic settings**

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

---

**Creating an IAM role on AWS**

You need an IAM role to delegate permissions to the AWS service to be used by your Job. If this IAM role does not exist, define it on AWS.

**Before you begin**

- You have the appropriate rights and permissions to create a new role on AWS.

**Procedure**

1. Log in to your account on AWS and navigate to the AWS console.
2. Select IAM.
3. In the navigation pane of the IAM console, select Roles, and then select Create role.
4. Select AWS service and in the Choose the service that will use this role section, select the AWS service to be run with your Job. For example, select Redshift.
5. Select the use case to be used for this service. An use case in terms of AWS is defined by the service to include the trust policy that this service requires. Depending on the service and the use case that you selected, the available options vary. For example, with Redshift, you can choose an use case from:
   - Redshift (with a pre-defined Amazon Redshift Service Linked Role Policy);
   - Redshift - Customizable. In this use case, you are prompted to select either read-only policies or full-access policies.

6. In the Role name field, enter the name to be used for the role being created.

7. Select Create role.

Results
A custom role has been created to delegate permissions to an AWS service. For the full documentation about creating a role on AWS, see Role creation from the AWS documentation.

Setting up SSE KMS for your EMR cluster

If required by the security policy of your organization, you need to set up SSE KMS, the server-side encryption service of Amazon, for the EMR cluster to be used, before creating this cluster.

About this task
This procedure explains only the SSE KMS related operations for getting started with the security configuration for EMR. If you need the complete information about all the available EMR security configurations provided by AWS, see Create a Security Configuration from the Amazon documentation.

Procedure
1. If not yet done, create a customer managed CMK to be used by the SSE KMS service by following this tutorial from the AWS documentation.
2. On the IAM console, in the Encryption keys tab, select the region where the CMK to be used was created from the Region drop-down list, click the CMK mentioned in the previous step to open its configuration view and in this view, add users or roles to be the Key Users of this customer managed CMK. Among other users/roles to be added depending on your security policy, you must add the EMR_EC2_DefaultRole role.
   The EMR_EC2_DefaultRole role allows your Jobs for Apache Spark to read or write files encrypted with SSE-KMS on S3.
   This role is a default AWS role that is automatically created along with the creation of your first EMR cluster. If this role and its associated policies do not exist in your account, see Use Default IAM Roles and Managed Policies from the AWS documentation.
3. On the Amazon EMR page of AWS, select the **Security configurations** tab and click **Create** to open the **Create security configuration** view.

4. Select the **At-rest encryption** check box to enable SSE KMS.

5. Under **S3 data encryption**, select **SSE-KMS** for **Encryption mode** and select the CMK key mentioned at the beginning of this procedure for **AWS KMS Key**.

6. Under **Local disk encryption**, select **AWS KMS** for **Key provider type** and select the CMK key mentioned at the beginning of this procedure for **AWS KMS Key**.

   **Example**

   ![Create security configuration](example.png)

   - **Name**: your_security_config_name
   - **Encryption mode**: SSE-KMS
   - **AWS KMS Key**: cmk_123456
   - **Key provider type**: AWS KMS

7. Click **Create** to validate your security configuration.
In the real-world practice, you can also configure the other security options such as Kerberos and IAM roles for EMRFS before clicking this Create button.

8. Click Clusters and once the Create Cluster page is open, click Go to advanced options to start creating the EMR cluster step by step.

9. At the last step called Security, in the Authentication and encryption section, select the Security Configuration created in the previous steps.

**Related scenario**

For tS3Connection related scenarios, see Exchange files with Amazon S3 on page 3324.
tS3Copy

Copies an Amazon S3 object from a source bucket to a destination bucket.

**tS3Copy Standard properties**

These properties are used to configure tS3Copy running in the Standard Job framework.

The Standard tS3Copy component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Access Key</td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the access key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
</tbody>
</table>
| Assume role                                  | Select this check box and specify the values for the following parameters used to create a new assumed role session.  
  • Role ARN: the Amazon Resource Name (ARN) of the role to assume.  
  • Role session name: an identifier for the assumed role session.  
  • Session duration (minutes): the duration (in minutes) for which we want to have the assumed role session to be active.  
  For more information on assuming roles, see AssumeRole. | |
<p>| Region                                       | Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g., &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints. |
| Source Bucket                                | Specify the name of the source bucket that contains the object to be copied.                                                                                                                                  |</p>
<table>
<thead>
<tr>
<th><strong>Source Key</strong></th>
<th>Specify the key of the object to be copied.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Destination Bucket</strong></td>
<td>Specify the name of the destination bucket to which the object will be copied.</td>
</tr>
<tr>
<td><strong>Destination Key</strong></td>
<td>Specify the new key for the object after being copied to the destination bucket.</td>
</tr>
</tbody>
</table>
| **Server-Side Encryption** | Select this check box to enable server-side encryption with Amazon S3-Managed Encryption Keys (SSE-S3) and use the 256-bit Advanced Encryption Standard (AES-256) cipher to encrypt your data.  
For more information about the server-side encryption, see Protecting Data Using Server-Side Encryption. |
| **Use KMS** | Select this check box to enable server-side encryption with AWS KMS-Managed Keys (SSE-KMS) instead of Amazon S3-Managed Encryption Keys (SSE-S3).  
This property is available when the Server-Side Encryption check box is selected. |
| **Customer Master Key** | Specify your own customer master key (CMK) that is created in the IAM console using AWS Key Management Service for SSE-KMS encryption. If not specified, the default CMK, which is created the first time you add an SSE-KMS encrypted object to the defined bucket in your region, will be used for SSE-KMS encryption.  
This property is available when the Use KMS check box is selected. |
| **Die on error** | Select this check box to stop the execution of the Job when an error occurs.  
Clear the check box to skip any rows on error and complete the process for error-free rows. |

**Advanced settings**

| **Config client** | Select this check box and specify the client parameter(s) by clicking the [+] button to add as many rows as needed, each row for a client parameter, and then setting the value of the following fields for each parameter:  
- **Client Parameter**: click the cell and from the drop-down list displayed select the client parameter.  
- **Value**: enter the value for the selected parameter.  
This check box is available only when the Use an existing connection check box is cleared. |
| **Part size (Mb) for file larger than 5GB** | Specify the part size in MB. This parameter takes effect only when you copy an Amazon S3 object that is larger than 5 GB through multiple parts.  
Note that in the copy operation, the object’s metadata may drop during transition. |
| **STS Endpoint** | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from. |
This check box is available only when the **Assume role** check box is selected.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is selected. |

**Usage**

| Usage rule | This component can be used as a standalone component. |

### Copying an S3 object from one bucket to another

This scenario describes a Job that uploads a new object to an existing empty S3 bucket `bucket-src`, then copies the object from the bucket `bucket-src` to another existing empty S3 bucket `bucket-dst`, finally lists the object in the bucket `bucket-dst` to see whether the object is successfully copied.
Setting up the Job

Procedure

1. Create a new Job and add a **tS3Connection** component, a **tS3Put** component, a **tS3Copy** component, a **tS3List** component, a **tIterateToFlow** component, and a **tLogRow** component by typing their names on the design workspace or dropping them from the Palette.
2. Link the **tS3List** component to the **tIterateToFlow** component using a **Row > Iterate** connection.
3. Link the **tIterateToFlow** component to the **tLogRow** component using a **Row > Main** connection.
4. Link the **tS3Connection** component to the **tS3Put** component using a **Trigger > On Subjob Ok** connection.
5. Do the same to link the **tS3Put** component to the **tS3Copy** component and the **tS3Copy** component to the **tS3List** component.

Configuring the components

Creating a connection to Amazon S3

Procedure

1. Double-click the **tS3Connection** component to open its **Basic settings** view on the **Component** tab.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials required to access Amazon S3.
3. From the **Region** drop-down list, select an AWS region where the object will be uploaded and copied. In this example, we keep the default setting.

Uploading an object to an Amazon S3 bucket

Procedure

1. Double-click the **tS3Put** component to open its **Basic settings** view on the **Component** tab.
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field, enter the name of the S3 bucket where the object will be uploaded. In this example, it is *bucket-src* that already exists in Amazon S3.

4. In the **Key** field, enter the key for the object to be uploaded. In this example, it is *tS3Copy_icon32_src.png*.

5. In the **File** field, browse to or enter the path to the object to be uploaded. In this example, it is *D:/tS3Copy_icon32.png*.

**Copying the uploaded object to another Amazon S3 bucket**

**Procedure**

1. Double-click the **tS3Copy** component to open its **Basic settings** view on the **Component** tab.

   ![tS3Copy component settings](image)

   - **Connection**: Use an existing connection
   - **Source Configuration**
     - **Bucket**: bucket-src
     - **Key**: tS3Copy_icon32_src.png
   - **Destination Configuration**
     - **Bucket**: bucket-dst
     - **Key**: tS3Copy_icon32_dst.png

   - **Server-Side Encryption**
   - **Die on error**

2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field in the **Source Configuration** area, enter the name of the bucket which contains the object to be copied. In this example, it is *bucket-src*.

4. In the **Key** field in the **Source Configuration** area, enter the key of the object to be copied. In this example, it is *tS3Copy_icon32_src.png*.

5. In the **Bucket** field in the **Destination Configuration** area, enter the name of the bucket to which the object will be copied. In this example, it is the empty one *bucket-dst* that already exists in Amazon S3.

6. In the **Key** field in the **Destination Configuration** area, enter the new key for the object after being copied to the destination bucket. In this example, it is *tS3Copy_icon32_dst.png*.

**Listing the object in the destination bucket**

**Procedure**

1. Double-click the **tS3List** component to open its **Basic settings** view on the **Component** tab.
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. Clear the **List all buckets objects** check box, and then click the [+] button to add one row in the **Bucket** table displayed and set the value for each column. In this example, *bucket-dst* for the **Bucket name** column and empty value for the **Key prefix** column, this way only the objects in the *bucket-dst* bucket will be listed.

4. Double-click the **tIterateToFlow** component to open its **Basic settings** view on the **Component** tab.

5. Click the [...] button next to **Edit schema** and in the pop-up schema dialog box define the schema by adding one column **ObjectList** of **String** type.

6. Click **OK** to save the changes and in the pop-up dialog box click **Yes** to accept the propagation.

7. Double-click the **tLogRow** component to open its **Basic settings** view on the **Component** tab.
8. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```
[statistics] connecting to socket on port 3491
[statistics] connected
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>ObjectList</td>
</tr>
<tr>
<td>tS3Copy_icon32.png</td>
</tr>
</tbody>
</table>

[statistics] disconnected
```

As shown above, the uploaded object has been copied to the destination bucket successfully.
tS3Delete

Deletes a file from Amazon S3.

tS3Delete Standard properties

These properties are used to configure tS3Delete running in the Standard Job framework.
The Standard tS3Delete component belongs to the Cloud family.
The component in this framework is available in all Talend products.

Basic settings

<table>

</table>
### Key prefix
Enter the prefix of files to be listed. This way, only files with that prefix will be listed.

#### Bucket
Click the [+] button to add one or more lines for defining the buckets and file prefixes.

- **Bucket name**: name of the bucket, namely the top level folder, whose files will be listed.
- **Key prefix**: prefix of files to be listed.

Not available when **List all bucket objects** is selected.

#### Die on error
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Config client
Select this check box to configure client parameters.

- **Client parameter**: select client parameters from the list.
- **Value**: enter the parameter value.

Not available when **Use existing connection** is selected.

#### STS Endpoint
Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.

#### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>CURRENT_BUCKET_NAME</strong></td>
<td>The current bucket name. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>CURRENT_KEY</strong></td>
<td>The current key. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>NB_BUCKET</strong></td>
<td>The number of buckets. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_BUCKET_OBJECT</strong></td>
<td>The number of objects in all buckets. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is selected.</td>
</tr>
</tbody>
</table>

### Usage

| Usage rule | This component can be used alone or with other S3 components, e.g. **tS3Delete**. |
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2472 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 495. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Listing files with the same prefix from a bucket

In this scenario, tS3List is used to list all the files in a bucket which have the same prefix.

There are such files in this bucket:

![S3 Browser](image)

For how to create a bucket and put files into it, see Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3286 and Exchange files with Amazon S3 on page 3324.

Linking the components

**Procedure**

1. Drop tS3Connection, tS3List, tIterateToFlow, tLogRow and tS3Close onto the workspace.
2. Link tS3Connection to tS3List using the OnSubjobOk trigger.
3. Link tS3List to tIterateToFlow using the Row > Iterate connection.
4. Link tIterateToFlow to tLogRow using the Row > Main connection.
5. Link tS3List to tS3Close using the OnSubjobOk trigger.
Configuring the components

Procedure

1. Double-click tS3Connection to open its Basic settings view.

2. In the Access Key and Secret Key fields, enter the authentication credentials.

3. Double-click tS3List to open its Basic settings view.
4. Select the **Use existing connection** check box to reuse the connection.
5. In the **Bucket** area, click the [*] button to add one line.
6. In the **Bucket name** and **Key prefix** fields, enter the bucket name and file prefix. 
   This way, only files with the specified prefix will be listed.
7. Double-click **tIterateToFlow** to open its **Basic settings** view.

8. Click **Edit schema** to open the schema editor.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N..</th>
<th>Date Pat..</th>
<th>Len..</th>
<th>Pre..</th>
<th>D..</th>
<th>Co..</th>
</tr>
</thead>
<tbody>
<tr>
<td>file_list</td>
<td></td>
<td>String</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Click the [*] button to add one column, namely **file_list** of the String type.
Click **Ok** to validate the setup and close the schema editor.

9. In the **Mapping** area, press **Ctrl + Space** in the **Value** field to choose the variable **tS3List_1_CURR
tENT_KEY**.

10. Double-click **tLogRow** to open its **Basic settings** view.

<table>
<thead>
<tr>
<th>Mode</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Basic</td>
<td></td>
</tr>
<tr>
<td>Table (print values in cells of a table)</td>
<td>(String)globalMap.get(&quot;tS3List_1_CURRENT_KEY&quot;)</td>
</tr>
</tbody>
</table>

Select **Table (print values in cells of a table)** for a better display of the results.

11. Double-click **tS3Close** to open its **Basic settings** view.
There is no need to select a connection component as the only one is selected by default.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```
[statistics] connecting to socket on port 3704
[statistics] connected
```
```
tLogRow_1
| ---
| file_list
| ---
| in-01.xls
| in-02.xls
```

[statistics] disconnected

As shown above, only the files with the prefix "in" are listed.
**tS3Put**

Uploads data onto Amazon S3 from a local file or from cache memory via the streaming mode.

**tS3Put Standard properties**

These properties are used to configure tS3Put running in the Standard Job framework.

The Standard tS3Put component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>

</tbody>
</table>
to Amazon S3. For more information, see Protecting Data Using Client-Side Encryption.

- **KMS-managed customer master key**: use a KMS-managed customer master key (CMK) for the client-side data encryption. In the **Key** field, you need to specify the AWS KMS customer master key ID (CMK ID).
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named AES.
  - **Encoding**: select the encoding type associated with the key from the list, either Base64 or X509.
  - **Key or Key file**: specify the key or the path to the file that stores the key.

- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named AES.
  - **Encoding**: select the encoding type associated with the key from the list, either Base64 or X509.
  - **Key or Key file**: specify the key or the path to the file that stores the key.

- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named RSA.
  - **Public key file**: specify the path to the public key file.
  - **Private key file**: specify the path to the private key file.

<table>

</table>

### Config client

- **Client parameter**: select client parameters from the list.
- **Value**: enter the parameter value.
- Not available when **Use existing connection** is selected.

### Enable Accelerate Mode

- Select this check box to enable fast, easy and secure transfers of files over long distances between your client and an S3 bucket. To take it into account, you should enable this acceleration mode on the S3 bucket in advance.

### STS Endpoint

- Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.
- This check box is available only when the **Assume role** check box is selected.

### Part size (Mb)

- Specify the part size in MB when uploading a large file in parts. For more information about S3 multipart upload, see [Multipart Upload Overview](#).

### tStatCatcher Statistics

- Select this check box to collect log data at the component level.

Exchange files with Amazon S3

In this scenario, **tS3Put** is used to send a file to the Amazon S3 server while **tS3Get** is used to get that file.

**Linking the components**

**Procedure**

1. Drop **tS3Connection**, **tS3Put** and **tS3Get** onto the workspace.
2. Link **tS3Connection** to **tS3Put** using the **OnSubjobOk** trigger.
3. Link **tS3Put** to **tS3Get** using the **OnSubjobOk** trigger.

**Configuring the components**

**Procedure**

1. Double-click **tS3Connection** to open its **Basic settings** view.
2. In the **Access Key** and **Secret Key** fields, enter the authentication credentials.

3. Double-click **tS3Put** to open its **Basic settings** view.

4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** field, enter the bucket name.

6. In the **Key** field, enter the name of the file to be saved on the S3 server.

7. In the **File** field, enter the file to be uploaded to the S3 server.

8. Double-click **tS3Get** to open its **Basic settings** view.

9. Select the **Use existing connection** check box to reuse the connection.

10. In the **Bucket** field, enter the bucket name.

11. In the **Key** field, enter the name of the file to be retrieved from the S3 server.

12. In the **File** field, enter the local name of the retrieved file.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to run the Job.
Starting job s3_put_get at 14:22 08/10/2013.

[statistics] connecting to socket on port 3950
[statistics] connected
[statistics] disconnected

Job s3_put_get ended at 14:22 08/10/2013. [exit code=0]

3. Go to the S3 web console:

As shown above, the file has been put on to the S3 server.

4. Refresh the S3 Browser client:

This shows that the S3 Put action was performed successfully.

5. Go to the folder where the retrieved file is saved locally:

As shown above, the remote file is retrieved to the local disk, proof that the S3 Get action was performed successfully.
**tSageX3Input (deprecated)**

Extracts data from a given Sage X3 system.

This component leverages the Web service provided by a given Sage X3 Web server to extract data from the Sage X3 system (the X3 server).

**tSageX3Input Standard properties**

These properties are used to configure tSageX3Input running in the Standard Job framework.

The Standard tSageX3Input component belongs to the Business family.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
|---|---|
| • View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |  
| Built-in: No property data stored centrally. |  
| Repository: Select the repository file where properties are stored. The fields that come after are pre-filled in using the fetched data. |  
| Endpoint address | Type in the address of the Web service provided by the given Sage X3 Web server. |  
| Username and Password | Type in the Web service user authentication data that you have defined for configuring the Sage X3 Web server.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |  
<p>| Language | Type in the name of the X3 language code used to start a connection group. |</p>
<table>
<thead>
<tr>
<th><strong>Pool alias</strong></th>
<th>Type in the name of the connection pool that distributes the received requests to available connections. This name was given from the Sage X3 configuration console.</th>
</tr>
</thead>
</table>
| **Request config** | Type in the configuration string if you want to retrieve the debug or trace information. For example, the string could be:  
RequestConfigDebug="adxwss.trace.on=on";  
If you need to use several strings, separate them with a &, for example,  
RequestConfigDebug="adxwss.trace.on=on&adxwss.trace.size=16384";  
**Warning:**  
A third party tool is needed to retrieve this kind of information. |
| **Publication name** | Type in the publication name of the published object, list or sub-program you want your Studio to access. |
| **Action** | Select in the list the action to be carried on.  
- **getAllDetails**: returns the details of all the records.  
- **getSummary**: returns the summary of each record.  
- **getDetail**: returns the details of the records that meet the conditions configured in the **Query condition** table. |
| **Mapping** | Complete this table to map the variable elements of the object, the sub-program or the list set in the given Sage X3 Web server. The columns to be completed include:  
Column: the columns defined in the schema editor for this component.  
Group ID: the identifier of each variable element group. For example, a variable element group could represent one of attributes of an object.  
Field name: the field name of each variable element. |
| **Conditions** | Complete this table to set up the query condition(s). The columns to be completed include:  
Key: the names of the variable elements used as the key for data extraction.  
Value: the value of the given key field used to extract the corresponding data.  
Available when **getDetail** is selected in the **Action** list. |
| **Query condition** | Select this check box to set up the query condition(s). The columns to be completed include:  
Key: the names of the variable elements used as the key for data extraction.  
Value: the value of the given key field used to extract the corresponding data.  
Not available when **getDetail** is selected in the **Action** list. |
| **Limit** | Type in a number to indicate the maximum row count of the data to be extracted. |
Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | Usually used as a Start component. An output component is required. |

Using query key to extract data from a given Sage X3 system

This scenario describes a two-component Job used to extract one row of data from a given Sage X3 system. The object method is to be called, that means the variable elements of this object thus are attributes. The data used in this scenario can be found in the example provided by Sage X3.

Setting up the Job

Procedure

1. Drop the tSageX3Input component and the tLogRow components onto the workspace from Palette.
2. Connect the tSageX3Input component to the tLogRow component using a Row > Main link.
Configuring the schema of tSageX3Input

Procedure

1. Double-click **tSageX3Input** to set its properties in the **Basic Settings** view.

2. In the **Schema** field, select **Built-In** and click the three-dot button next to **Edit schema** to open the schema editor.
3. In this editor, click the plus button 12 times beneath the schema table to add 12 rows into this table.

4. Type in the names you want to use for each row. In this example, these rows are named after the publication names of the object attributes set in the Sage X3 Web server. These columns are used to map the corresponding attribute fields in the Sage X3 system.

5. In the **Type** column, click the **IMG** row to display its drop-down list.

6. From the drop-down list, select **List** as this attribute appears twice or even more and do the same to switch the types of the **TIT2NBLIG** row, the **ITMLNK** row and the **ZITMLNK** row to **List** as well for the same reason.

7. Click **OK** to validate this change and accept the propagation prompted by a pop-up dialog box.

**Configuring the connection to the Sage X3 Web server**

**Procedure**

1. In the **Endpoint address** field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is `http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC`

2. In the **User** field, type in the user name of the given Sage X3. In this example, it is **ERP**.

3. In the **Language** field, type in the name of the X3 language code used to start a connection group. In this example, it is **FRA**.

4. In the **Pool alias** field, type in the name of connection pool to be used. In this example, this connection pool is called **TALEND**.

5. In the **Publication name** field, type in the publication name of the object to be called. In this scenario, the publication name is **ITMDET**.

**Setting up the mapping and configuring the query condition**

**Procedure**

1. In the **Group ID** column and the **Field name** column of the **Mapping** table, type in values corresponding to the attribute group IDs and the attribute publication names defined in the Sage X3 Web server. In this example, the values are presented in the figure below.
2. Select the **Query condition** check box to activate the **Conditions** table.

3. Under the **Conditions** table, click the plus button to add one row into the table.

4. In the **Key** column, type in the publication name associated with the object attribute you need to extract data from.

5. In the **Value** column, type in the value of the attribute you have selected as the key of the data extraction. In this scenario, it is *CONTS00059*, one of the product references.

---

### Job execution

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

   The results are displayed on the **Run** console:
tSageX3Output (deprecated)

Writers data into a given Sage X3 system.
This component connects to the Web service provided by a given Sage X3 Web server and therefrom insert, update or delete data in the Sage X3 system (the X3 server).

tSageX3Output Standard properties

These properties are used to configure tSageX3Output running in the Standard Job framework.
The Standard tSageX3Output component belongs to the Business family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint address</td>
<td>Type in the address of the Web service provided by the given Sage X3 Web server.</td>
</tr>
</tbody>
</table>
| Username and Password | Type in the Web service user authentication data that you have defined for configuring the Sage X3 Web server.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
<table>
<thead>
<tr>

| **Request config** | Type in the configuration string if you want to retrieve the debug or trace information.  
For example, the string could be: "RequestConfigDebug="adxwss.trace.on=on";"  
If you need use several strings, separate them with a & , for example,  
RequestConfigDebug="adxwss.trace.on=on&adxwss.trace.size=16384";  
**Warning:**  
A third party tool is needed to retrieve this kind of information. |
| **Publication name** | Type in the publication name of the published object, list or sub-program you want your Studio to access. |
| **Action** | You can do any of the following operations on the data in a Sage X3 system:  
**Insert**: insert data  
**Update**: update data  
**Delete**: delete data |
| **Mapping** | Complete this table to map the variable elements of the object, the list or the sub-program your Studio access. Only the elements you need to conduct the data action of your interest on are selected and typed in for the purpose of mapping. The columns to be completed include:  
**Column**: the columns defined in the schema editor for this component.  
**Key**: the variable element used as key for data insertion, update or deletion. Select the corresponding check box if a variable element is the key.  
**Group ID**: the identifier of each variable element group. For example, a variable element group could represent one of attributes of an object.  
**Field name**: the field name of each selected variable element. |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | Usually used as an output component. An input component is required. |

Using a Sage X3 Web service to insert data into a given Sage X3 system

This scenario describes a two-component Job used to generate one row of data and insert the data into a given Sage X3 system. You can find the data used in this scenario in the example provided by Sage X3. The Sage X3 Web service is used to access an object.

Setting up the Job

Procedure

1. Drop the tFixedFlowInput and the tSageX3Output components onto the workspace from Palette.
2. Connect the tFixedFlowInput component to the tSageX3Output component using a Row > Main connection.

Configuring the schema for the input data

Procedure

1. Double-click the tFixedFlowInput component to set its Basic Settings in the Component view
2. Click the three-dot button next to **Edit schema** to open the schema editor.

3. In the schema editor and then under the schema table, click the plus button four times to add four rows.

4. Click **OK** to validate this changes and then accept the propagation prompted by the pop-up dialog box. The four rows appear automatically in the Values table of the Component view.

5. In the **Values** table within the **Mode** area, type in the values for each of the four rows in the **Value** column. In this scenario, the values downward are: `CONTS00059`, `Screen 24" standard 16/10`, `Screen 24" standard 28/10`, 2.

**Warning:**

*These values in the Value column must be put between quotation marks.*
Setting up the connection to the Sage X3 Web server

Procedure

1. Double-click tSageX3Output to set its properties from the Basic Settings view.

2. In the Endpoint address field, type in the URL address of the Web service provided by the Sage X3 Web server. In this example, it is http://10.42.20.168:28880/adxwsvc/services/CAdxWebServiceXmlCC

3. In the User field, type in the user name of the given Sage X3. In this example, it is ERP.

4. In the Language field, type in the name of the X3 language code used to start a connection group. In this example, it is FRA.

5. In the Pool alias field, type in the name of connection pool to be used. In this example, this connection pool is called TALEND.

6. In the Publication name field, type in the publication name of the object to be called. In this scenario, the publication name is ITMDET.

7. In the Action field, select insert from the drop-down list.

Setting up the mapping

Procedure

1. In the Field name column of the Mapping table, type in the field names of the attributes the selected data action is exercised on.

2. In the Group ID column of the Mapping table, type in values corresponding to group IDs of the selected attributes. These IDs are defined in the Sage X3 Web server.
Note:
In the Mapping table, the Column column has been filled automatically with the columns retrieved from the schema of the preceding component.

**Job execution**

Press CTRL+S to save your Job and press F6 to execute it.

To verify the data that you inserted in this scenario, you can use the tSageX3Input component to read the concerned data from the Sage X3 server.

For further information about how to use the tSageX3Input component to read data, see Using query key to extract data from a given Sage X3 system on page 3329.
tSalesforceBulkExec

Bulk-loads data in a given file into a Salesforce object.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

**tSalesforceBulkExec Standard properties**

These properties are used to configure tSalesforceBulkExec running in the Standard Job framework. The Standard tSalesforceBulkExec component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select the component that opens the database connection to be reused by this component.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Select the type of the connection from the drop-down list. The connection properties will vary according to the connection type you choose.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Basic</strong>: select this option to access Salesforce by entering your Salesforce username and password.</td>
</tr>
<tr>
<td></td>
<td>• <strong>OAuth</strong>: select this option to access Salesforce using OAuth (Open Authorization) 2.0 protocol to authenticate the user. From the OAuth2 flow type drop-down list displayed, you need to choose an OAuth 2.0 authentication flow type, either Json Web Token Flow or Implicit Flow (Deprecated) (User Agent Flow). This way, you need to create a connected app in Salesforce to configure a Salesforce authentication provider.</td>
</tr>
</tbody>
</table>

For more information about the OAuth authentication flow, see Authenticate Apps with OAuth.

For more information about how to create a connected app in Salesforce, see Create a Connected App.
| **User Id** | The Salesforce username.  
This property is available only when the **Basic** connection type is selected. |
| **Password** | The Salesforce password associated with the username.  
This property is available only when the **Basic** connection type is selected. |
| **Security Token** | The Salesforce security token. For more information, see [Reset Your Security Token].  
This property is available only when the **Basic** connection type is selected. |
| **Issuer** | The OAuth Consumer Key, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see [Create a Connected App].  
This property is available only when the OAuth **Json Web Token Flow** type is selected. |
| **Subject** | The Salesforce username.  
This property is available only when the OAuth **Json Web Token Flow** type is selected. |
| **Audience** | Json Web Token audience.  
You can set your own Json Web Token audience.  
This property is available only when **OAuth** is selected from the **Connection type** drop-down list and **Json Web Token Flow** is selected from the the **Oauth2 flow type** drop-down list. |
| **Expiration time (in seconds)** | The expiration time of the assertion (in seconds) within five minutes.  
This property is available only when the OAuth **Json Web Token Flow** type is selected. |
| **Key store** | The path to the keystore file in Java Keystore (JKS) format.  
The keystore file can be generated by creating a certificate signed by Salesforce and then exporting it to keystore. For more information, see [Generate a Self-Signed Certificate].  
This property is available only when the OAuth **Json Web Token Flow** type is selected. |
| **Key store password** | The keystore password.  
This property is available only when the OAuth **Json Web Token Flow** type is selected. |
| **Certificate alias** | The unique name of the certificate signed by Salesforce.  
This property is available only when the OAuth **Json Web Token Flow** type is selected. |
| **Client Id** | The OAuth Consumer Key, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see [Create a Connected App]. |
### SalesforceBulkExec

This property is available only when the OAuth Implicit Flow type is selected.

<table>
<thead>
<tr>
<th><strong>Client Secret</strong></th>
<th>The OAuth Consumer Secret, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see Create a Connected App. This property is available only when the OAuth Implicit Flow type is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Callback Host</strong></td>
<td>The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
<tr>
<td><strong>Callback Port</strong></td>
<td>The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
<tr>
<td><strong>Token File</strong></td>
<td>The path to the token file that stores the refresh token used to get the access token without authorization. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
<tr>
<td><strong>Module Name</strong></td>
<td>Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job. |
| **Output Action** | Select one of the following operations to be performed from the drop-down list. |
tSalesforceBulkExec

- **INSERT**: insert one or more new records into Salesforce.
- **UPDATE**: update one or more existing records in Salesforce.
- **UPSERT**: create new records and update existing records. In the **Upsert Key Column** field displayed, specify the key column for the upsert operation.
- **DELETE**: delete one or more records in Salesforce.

### Bulk File Path
Specify the path to the file that stores the data to be processed.

### Advanced settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Salesforce URL</td>
<td>The Webservice URL required to connect to Salesforce.</td>
</tr>
<tr>
<td>API version</td>
<td>The Salesforce API version. This property is available only when the OAuth connection type is selected.</td>

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_SUCCESS</td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_REJECT</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component is more commonly used with the **tSalesforceOutputBulk** component. Used together, they gain performance while feeding or modifying information in Salesforce.

### Related scenario

No scenario is available for this component yet.
tSalesforceConnection

Opens a connection to Salesforce.

**tSalesforceConnection Standard properties**

These properties are used to configure tSalesforceConnection running in the Standard Job framework. The Standard tSalesforceConnection component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

<td>Use Http Chunked</td>
<td>Select this check box to use the HTTP chunked data transfer mechanism. This property is available only when the Bulk Connection check box is cleared.</td>
</tr>
<tr>
<td>Trace HTTP message</td>
<td>Select this check box to output the HTTP interactions on the console. This property is available only when the Bulk Connection check box is selected.</td>
</tr>
</tbody>
</table>
### tSalesforceConnection

| Client Id | Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website. |
| Timeout | Enter the intended number of query timeout in milliseconds in Salesforce. |
| Use Proxy | Select this check box to use a proxy server, and in the Host, Port, User Id, and Password fields displayed, specify the connection parameters of the proxy server. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

### Usage

| Usage rule | This component is more commonly used with other Salesforce components. |

### Connecting to Salesforce using OAuth implicit flow to authenticate the user (deprecated)

In this scenario, the OAuth2 (Open Authorization 2.0) method is adopted to authorize tSalesforceConnection to access the Salesforce resources. This way, better security is achieved as users do not need entering their Salesforce username/password directly on tSalesforceConnection, which is required by the Basic login type instead.

### Setting up the Job

**Procedure**

1. Drop a tSalesforceConnection component, a tFixedFlowInput component and a tSalesforceOutput component onto the workspace.
2. Link the tFixedFlowInput component to the tSalesforceOutput component using a Row > Main connection.
3. Link the tSalesforceConnection component to the tFixedFlowInput component using a Trigger > OnSubjobOk connection.

**Configuring the components**

**Procedure**

1. Double-click the tSalesforceConnection component to open its Basic settings view.

   ![tSalesforceConnection](image)

   - Select OAuth from the Connection type drop-down list and Implicit Flow from the Oauth2 flow type drop-down list.
   - In the Client Id and Client Secret fields, enter the key and secret used by the consumer to access Salesforce respectively.
   - In the Callback Host and Callback Port fields, enter the callback host and port information respectively.
   - In the Token File field, browse to or enter the path to the token file that stores the refresh token used by the OAuth-enabled connected app to obtain new sessions without requiring the user to provide their credentials.

2. Double-click the tFixedFlowInput component to open its Basic settings view.

   ![tFixedFlowInput](image)

   - Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding one column Name of String type. When done, click OK to save the changes and close the dialog box.
8. In the Mode area, select Use Inline Content (delimited file). Then in the Content field displayed, enter the data to be written into Salesforce. For example, Talend.

9. Double-click the tSalesforceOutput component to open its Basic settings view.

10. Select the tSalesforceConnection component from the Connection Component drop-down list to reuse the connection created by it.

11. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object you want to access. In this example, it is Account.

12. Click the [...] button next to Edit schema to open the schema dialog box. On the right side of the panel, remove all the columns except the column Name. When done, click OK to save the changes and close the dialog box.

**Executing the Job**

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to run the Job. The Studio console gives the URL (in yellow) for OAuth authorization.
3. Copy the URL to the browser's address bar. The Salesforce.com login page appears.

![Salesforce login page]

4. Fill up the username and password and click **Log in to Salesforce**.
The authorization response is then shown on the browser at the callback host.

```
https://localhost:8446?code=5e764d87723b08f479007b37a82219521f653d8ac0ba3f7b3a8f5d761e
```

5. Now is the time for the Job to continue running.
As shown above, the Job is successfully executed.

6. Go to the Salesforce.com and check the Account object. You can find that the account whose name is Talend is inserted.

**Related scenario**

Upserting Salesforce data based on external IDs on page 3385
tSalesforceGetDeleted

Collects data deleted during a specific period of time from a Salesforce object.

**tSalesforceGetDeleted Standard properties**

These properties are used to configure tSalesforceGetDeleted running in the Standard Job framework. The Standard tSalesforceGetDeleted component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

### Usage

| **Usage rule** | This component is usually used as a start component of a Job or Subjob and it always needs an output link. |

### Recovering deleted data from Salesforce

This scenario describes a two-component Job that collects the account data deleted over the past five days from Salesforce.
Setting up the Job for recovering deleted data from Salesforce

Procedure

1. Create a new Job and add a `tSalesforceGetDeleted` component and a `tLogRow` component by typing their names on the design workspace or dropping them from the Palette.
2. Connect the `tSalesforceGetDeleted` component to the `tLogRow` component using a Row > Main connection.

Configuring the Job for recovering deleted data from Salesforce

Procedure

1. Double-click the `tSalesforceGetDeleted` component to open its Basic settings view.

   ![Basic settings view of tSalesforceGetDeleted component]

   - **User Id**: `lena557@foxmail.com`
   - **Password**: Password is hidden
   - **Security Key**: Password is hidden
   - **Module Name**: Account
   - **Start Date**: 2016-06-08
   - **End Date**: 2016-06-13

2. In the User Id, Password and Security Key fields, enter the user authentication information required to access Salesforce.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object you want to access. In this example, it is Account. When done, click OK to save the settings and close the dialog box.
4. Click the [...] button next to the **Start Date** field and in the pop-up calendar dialog box, set the value of the start date and time to collect only the data deleted since the specified time. In this example, it is 2016-06-08 00:00:00.

5. Do the same to set the value of the end date and time in the **End Date** field to collect only the data deleted before the specified time. In this example, it is 2016-06-13 00:00:00.

6. Double-click the **tLogRow** component to open its **Basic settings** view.
7. Click **Sync columns** to retrieve the schema from the preceding component.

8. In the **Mode** area, select **Vertical (each row is a key/value list)** to display the results in a tabular form on the console.

**Executing the Job to recover deleted data from Salesforce**

**Procedure**

1. Press **Ctrl + S** to save your Job.
2. Press **F6** to run your Job.
As shown above, the data deleted during the past five days is collected and displayed in a tabular form on the console.
tSalesforceGetServerTimestamp

Retrieves the current date of the Salesforce server presented in a timestamp format.

tSalesforceGetServerTimestamp Standard properties

These properties are used to configure tSalesforceGetServerTimestamp running in the Standard Job framework.

The Standard tSalesforceGetServerTimestamp component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Built-In</strong>: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository</strong>: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

| Connection Component | Select the component that opens the database connection to be reused by this component. |

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Select the type of the connection from the drop-down list. The connection properties will vary according to the connection type you choose.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• <strong>Basic</strong>: select this option to access Salesforce by entering your Salesforce username and password.</td>
</tr>
<tr>
<td></td>
<td>• <strong>OAuth</strong>: select this option to access Salesforce using OAuth (Open Authorization) 2.0 protocol to authenticate the user. From the <strong>OAuth2 flow type</strong> drop-down list displayed, you need to choose an OAuth 2.0 authentication flow type, either <strong>Json Web Token Flow</strong> or <strong>Implicit Flow (Deprecated)</strong> (User Agent Flow). This way, you need to create a connected app in Salesforce to configure a Salesforce authentication provider.</td>
</tr>
<tr>
<td></td>
<td>For more information about the OAuth authentication flow, see <a href="#">Authenticate Apps with OAuth</a>.</td>
</tr>
<tr>
<td></td>
<td>For more information about how to create a connected app in Salesforce, see <a href="#">Create a Connected App</a>.</td>
</tr>
</tbody>

<td>---</td>
</tr>
<tr>
<td><strong>Callback Host</strong></td>
<td>The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
<tr>
<td><strong>Callback Port</strong></td>
<td>The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
<tr>
<td><strong>Token File</strong></td>
<td>The path to the token file that stores the refresh token used to get the access token without authorization. This property is available only when the OAuth Implicit Flow type is selected.</td>
</tr>
</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  • View schema: choose this option to view the schema only.  
  • Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |

**Advanced settings**

| **Salesforce URL** | The Webservice URL required to connect to Salesforce. |
| **API version** | The Salesforce API version. This property is available only when the OAuth connection type is selected. |
| **Use or save the connection session** | Select this check box and in the Session directory field displayed, specify the path to the connection session file to be saved or used. |
This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session.

When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file.

This property is available only when the Basic connection type is selected.

**Need compression**
Select this check box to activate SOAP message compression, which can result in increased performance levels.

**Use Http Chunked**
Select this check box to use the HTTP chunked data transfer mechanism.

**Client Id**
Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.

**Timeout**
Enter the intended number of query timeout in milliseconds in Salesforce.

**Use Proxy**
Select this check box to use a proxy server, and in the **Host**, **Port**, **User Id**, and **Password** fields displayed, specify the connection parameters of the proxy server.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

<table>

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
In this component the schema is related to the Module selected. To retrieve a column from a linked module it is necessary to define the column in a particular manner in the Edit schema view, otherwise the relationship query will not work. The correct syntax is: NameofCurrentModule_NameofLinkedModule_NameofColumnofInterest. |
| Query Mode        | Select the query mode from the drop-down list, either Query or Bulk.  
  - Query: the ordinary query. |
- **Bulk**: the bulk query used to query large data sets efficiently and reduce the number of API requests.

### Condition
Enter the query used to select the data to be extracted between double quotation marks, for example, "name='Talend'" or "name like '%talend_user%'". This property is not available when the **Manual Query** check box is selected.

### Manual Query
Select this check box and in the **Full SOQL query string** field displayed, enter the full SOQL (Salesforce Object Query Language) statement used to select the data to be retrieved between double quotation marks. For more information about the SOQL, see [Salesforce Object Query Language (SOQL)](https://www.salesforce.com/products/platform-api/). This property is not available when the **Manual Query** check box is selected.

### Guess schema
Click this button to generate the schema columns based on the query specified in the **Full SOQL query string** field. This property is available only when the **Manual Query** check box is selected. Note that there are some limitations you should be aware of when using this feature. Please refer to the Know Limitations section in Release Notes for more detailed information.

### Guess query
Click this button to generate the query in the **Full SOQL query string** field based on the defined module and schema. For more information about how to set the module and schema correctly when generating the SOQL queries, see [How to set schema for the guess query feature of tSalesforceInput on page 3374](#). This property is available only when the **Manual Query** check box is selected. Note that there are some limitations you should be aware of when using this feature. Please refer to the Know Limitations section in Release Notes for more detailed information.

### Include deleted records
Select this check box to query all the records, including the deleted ones. This property is available only when **Query** is selected from the **Query Mode** drop-down list.

### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Salesforce URL</td>
<td>The Webservice URL required to connect to Salesforce.</td>
</tr>
<tr>
<td>API version</td>
<td>The Salesforce API version. This property is available only when the <strong>OAuth</strong> connection type is selected.</td>
</tr>
<tr>
<td>Use or save the connection session</td>
<td>Select this check box and in the <strong>Session directory</strong> field displayed, specify the path to the connection session file to be saved or used. This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided</td>
</tr>
</tbody>
</table>
by the component. This way, you do not need to connect to the server to retrieve the session.

When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file.

This property is available only when the Basic connection type is selected.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Need compression</td>
<td>Select this check box to activate SOAP message compression, which can result in increased performance levels.</td>
</tr>
<tr>
<td>Trace HTTP message</td>
<td>Select this check box to output the HTTP interactions on the console. This property is available only when Bulk is selected from the Query Mode drop-down list.</td>
</tr>
<tr>
<td>Use HTTP Chunked</td>
<td>Select this check box to use the HTTP chunked data transfer mechanism. This property is available only when Query is selected from the Query Mode drop-down list.</td>
</tr>
<tr>
<td>Client Id</td>
<td>Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Enter the intended number of query timeout in milliseconds in Salesforce.</td>
</tr>
<tr>
<td>Use Proxy</td>
<td>Select this check box to use a proxy server, and in the Host, Port, User Id, and Password fields displayed, specify the connection parameters of the proxy server.</td>
</tr>
<tr>
<td>Batch Size</td>
<td>Enter the number of registrations in each processed batch. This property is available only when Query is selected from the Query Mode drop-down list.</td>
</tr>
<tr>
<td>Normalize Delimiter</td>
<td>Enter the characters, strings or regular expressions used to normalize the data that is collected by queries set on different hierarchical Salesforce objects. This property is available only when Query is selected from the Query Mode drop-down list.</td>
</tr>
<tr>
<td>Column Name Delimiter</td>
<td>Enter the characters, strings or regular expressions used to separate the name of the parent object from the name of the child object when you use a query on the hierarchical relations among the different Salesforce objects. This property is available only when Query is selected from the Query Mode drop-down list.</td>
</tr>
<tr>
<td>Safety Switch</td>
<td>Clear this check box if the length of any column of the module to be queried is greater than 100,000 characters. By default, this check box is selected to prevent excessive memory usage. This property is available only when Bulk is selected from the Query Mode drop-down list.</td>
</tr>
</tbody>
</table>
### Complete Job timeout

The timeout value, in seconds, within which your bulk query Job must be completed. By default, the value is set to 0, which means there is no time limit for your Job to complete.

Salesforce has its own limit for bulk query. If it takes time longer than Salesforce’s timeout limit to process a batch, the batch will be placed in a queue and processed later, and thus it might take too much time for the Job to execute. In this case, you can define the Complete Job timeout value to make your Job end in advance. For more information about Salesforce’s own limit, see Bulk API Limits - Batch processing time.

This property is available only when **Bulk** is selected from the **Query Mode** drop-down list.

### Enable PK Chunking

Select this check box to enable PK (Primary Key, i.e., the object’s record ID) chunking when extracting large amounts of records or when the query consistently times out. In the **Chunk size** field displayed, specify the number of records within the ID boundaries for each chunk. For more information, see Use PK Chunking to Extract Large Data Sets from Salesforce.

This property is available only when **Bulk** is selected from the **Query Mode** drop-down list.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component is usually used as a start component of a Job or Subjob and it always needs an output link.</td>
</tr>
</tbody>
</table>

### How to set schema for the guess query feature of **tSalesforceInput**

**tSalesforceInput** allows you to generate SOQL queries, with both standard objects and fields and custom objects and fields, based on the defined module and schema. This section demonstrates how to set the module and schema when generating an SOQL query.

There are two types of SOQL queries: simple query and relationship query.

Simple query retrieves data from only one object. For more information about how to set the module and schema for generating simple queries, see How to set schema for generating the simple query on page 3375.
Relationship query retrieves data from more than a single type of object, including child-to-parent and parent-to-child relationship queries.

For more information about how to set the module and schema for generating child-to-parent relationship queries, see How to set schema for generating the child-to-parent relationship query on page 3375.

For more information about how to set the module and schema for generating parent-to-child relationship queries, see How to set schema for generating the parent-to-child relationship query on page 3377.

Note that before setting the module name and schema columns for generating the relationship query in the Basic settings view of tSalesforceInput, you need to first identify the relationship type (child-to-parent or parent-to-child) of the query to be generated, because the methods of setting the schema column names for these two kinds of relationship queries are somewhat different. The main difference between the child-to-parent and parent-to-child relationship queries is that the parent-to-child relationship query is specified by using the subquery enclosed in parentheses, while the child-to-parent relationship query is not. For more information about the relationship queries in SOQL and how to identify the relationship queries, see Relationship Queries.

How to set schema for generating the simple query

This section demonstrates how to set the module name and schema columns for generating the simple query.

The following two simple query examples will be used for demonstration purpose in the following steps.

- SELECT Id, Name, BillingCity FROM Account, a simple query with standard object and fields, and
- SELECT Name__c, LastName__c FROM Mother__c, a simple query with custom object and fields.

Procedure

1. Set the module name with the name of the object specified in the FROM clause, Account and Mother__c for above examples.
2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box and set the column name with the field name.
   
   For the first example, you need to create three columns Id, Name, and BillingCity for the three fields.
   
   For the second example, you need to create two columns Name__c and LastName__c for the two fields.

How to set schema for generating the child-to-parent relationship query

This section demonstrates how to set the module name and schema columns for generating a child-to-parent relationship query.

The following two child-to-parent relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Account.Name, Account.Owner.Name FROM Contact, a child-to-parent relationship query with standard object and fields, and
• SELECT Id, FirstName__c, MotherOfDaughter__r.FirstName__c FROM Daughter__c, a child-to-parent relationship query with custom object and fields.

Note that here you must use the relationship name with __r instead of __c. For more information, see Understanding Relationship Names, Custom Objects, and Custom Fields.

Procedure

1. Set the module name with the name of the object specified in the FROM clause, Contact and Daughter__c in above examples.

2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box.

   For the first example, you need to create three columns for the three fields Name, Account.Name, and Account.Owner.Name.

   For the second example, you need to create three columns for the three fields Id, FirstName__c, and MotherOfDaughter__r.FirstName__c.

3. Set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

   For the first example, the names of the three columns are set to Name, Account_Name, and Account_Owner_Name.

   For the second example, the names of the three columns are set to Id, FirstName__c, and MotherOfDaughter__r_FirstName__c.

4. Set the type of each column.

   The schema for the first example should be set like this:

   ![schema.png](attachment://schema.png)

   And the schema for the second example should be set like this:
Note that the underscore character '_' is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character '_' that goes after '__r' or '__c' will be replaced by the dot character '.' when generating the query. If the underscore character '_' is a part of any custom name in the schema, for example, Contact_custom_field__c, which should be Contact.custom_field__c in the query, you need to replace '_' in the generated query with '.' manually.

How to set schema for generating the parent-to-child relationship query

This section demonstrates how to set the module name and schema columns for generating a parent-to-child relationship query.

The following two parent-to-child relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Owner.Name (SELECT CreatedBy.Name FROM Notes) FROM Account, a parent-to-child relationship query with standard object and fields, and
- SELECT LastName__c, (SELECT FirstName__c FROM Daughters__r) FROM Mother__c, a parent-to-child relationship query with custom object and fields.

Note that here you must use the relationship name with __r instead of __c. For more information, see Understanding Relationship Names, Custom Objects, and Custom Fields.

Procedure

1. Set the module name with the name of the object specified in the outer query FROM clause, Account and Mother__c in above examples.
2. Create a column for each field (including the fields in subquery) after SELECT in the schema dialog box.

For the first example, you need to create three columns for the three fields, including two fields Name and Owner.Name after the outer SELECT, and one field CreatedBy.Name after the subquery SELECT.

For the second example, you need to create two columns for the two fields, including the field LastName__c after the outer SELECT, and the field FirstName__c after the subquery SELECT.
3. For the fields in the outer SELECT clause, which are outside parentheses, set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

For the first example, the column names for the two fields Name and Owner.Name in the outer SELECT clause are set to Name and Owner_Name.

For the second example, there is no dot in the field name, so the column name is same as the field name.

4. For the fields in the subquery SELECT, construct the column names using the pattern `<$XXX>_records_<$YYY>`, where `<$XXX>` corresponds to the name of the object specified in the subquery FROM clause, and `<$YYY>` will be the field name with all dots replaced by underscore characters.

For the first example, the column name for the field CreatedBy.Name in the subquery is set to Notes_records_CreatedBy_Name.

For the second example, the column name for the field FirstName__c in the subquery is set to Daughters__r_records_FirstName__c.

5. Set the type of each column.

The schema for the first example should be set like this:

![First example schema](image1)

And the schema for the second example should be set like this:

![Second example schema](image2)
Note that the underscore character ‘_’ is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character ‘_’ that goes after ‘__r’ or ‘__c’ will be replaced by the dot character ‘.’ when generating the query. If the underscore character ‘_’ is a part of any custom name in the schema, for example, Contact_custom_field__c, which should be Contact.custom_field__c in the query, you need to replace ‘_’ in the generated query with ‘.’ manually.

**Related scenario**

Upserting Salesforce data based on external IDs on page 3385
tSalesforceOutput

Inserts, updates, upserts, or deletes data in a Salesforce object.

tSalesforceOutput Standard properties

These properties are used to configure tSalesforceOutput running in the Standard Job framework.
The Standard tSalesforceOutput component belongs to the Business and the Cloud families.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Built-In: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• Repository: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select the component that opens the database connection to be reused by this component.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Select the type of the connection from the drop-down list. The connection properties will vary according to the connection type you choose.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Basic: select this option to access Salesforce by entering your Salesforce username and password.</td>
</tr>
<tr>
<td></td>
<td>• OAuth: select this option to access Salesforce using OAuth (Open Authorization) 2.0 protocol to authenticate the user. From the OAuth2 flow type drop-down list displayed, you need to choose an OAuth 2.0 authentication flow type, either Json Web Token Flow or Implicit Flow (Deprecated) (User Agent Flow). This way, you need to create a connected app in Salesforce to configure a Salesforce authentication provider.</td>
</tr>
</tbody>
</table>

For more information about the OAuth authentication flow, see Authenticate Apps with OAuth.

For more information about how to create a connected app in Salesforce, see Create a Connected App. |

<table>
<thead>
<tr>
<th>User Id</th>
<th>The Salesforce username. This property is available only when the Basic connection type is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Password</td>
<td>The Salesforce password associated with the username.</td>
</tr>
</tbody>
</table>
### Security Token
The Salesforce security token. For more information, see [Reset Your Security Token](#). This property is available only when the Basic connection type is selected.

### Issuer
The OAuth Consumer Key, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see [Create a Connected App](#). This property is available only when the OAuth Json Web Token Flow type is selected.

### Subject
The Salesforce username. This property is available only when the OAuth Json Web Token Flow type is selected.

### Audience
Json Web Token audience. You can set your own Json Web Token audience. This property is available only when OAuth is selected from the Connection type drop-down list and Json Web Token Flow is selected from the the Oauth2 flow type drop-down list.

### Expiration time (in seconds)
The expiration time of the assertion (in seconds) within five minutes. This property is available only when the OAuth Json Web Token Flow type is selected.

### Key store
The path to the keystore file in Java Keystore (JKS) format. The keystore file can be generated by creating a certificate signed by Salesforce and then exporting it to keystore. For more information, see [Generate a Self-Signed Certificate](#). This property is available only when the OAuth Json Web Token Flow type is selected.

### Key store password
The keystore password. This property is available only when the OAuth Json Web Token Flow type is selected.

### Certificate alias
The unique name of the certificate signed by Salesforce. This property is available only when the OAuth Json Web Token Flow type is selected.

### Client Id
The OAuth Consumer Key, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see [Create a Connected App](#). This property is available only when the OAuth Implicit Flow type is selected.

### Client Secret
The OAuth Consumer Secret, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see [Create a Connected App](#).
### Callback Host
The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.

This property is available only when the OAuth Implicit Flow type is selected.

### Callback Port
The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.

This property is available only when the OAuth Implicit Flow type is selected.

### Token File
The path to the token file that stores the refresh token used to get the access token without authorization.

This property is available only when the OAuth Implicit Flow type is selected.

### Module Name
Click the [ .. ] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Click Sync columns to retrieve the schema from the previous component connected in the Job.

### Output Action
Select one of the following operations to be performed from the drop-down list.

- **INSERT**: insert one or more new records into Salesforce.
- **UPDATE**: update one or more existing records in Salesforce.
- **UPSERT**: create new records and update existing records. In the Upsert Key Column field displayed, specify the key column for the upsert operation.
- **DELETE**: delete one or more records in Salesforce.
### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Salesforce URL</td>
<td>The Webservice URL required to connect to Salesforce.</td>
</tr>
<tr>
<td>API version</td>
<td>The Salesforce API version. This property is available only when the OAuth connection type is selected.</td>
</tr>
<tr>
<td>Use or save the connection session</td>
<td>Select this check box and in the Session directory field displayed, specify the path to the connection session file to be saved or used. This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session. When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file. This property is available only when the Basic connection type is selected.</td>
</tr>
<tr>
<td>Need compression</td>
<td>Select this check box to activate SOAP message compression, which can result in increased performance levels.</td>
</tr>
<tr>
<td>Use Http Chunked</td>
<td>Select this check box to use the HTTP chunked data transfer mechanism.</td>
</tr>
<tr>
<td>Client Id</td>
<td>Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.</td>
</tr>
<tr>
<td>Timeout</td>
<td>Enter the intended number of query timeout in milliseconds in Salesforce.</td>
</tr>
<tr>
<td>Use Proxy</td>
<td>Select this check box to use a proxy server, and in the Host, Port, User Id, and Password fields displayed, specify the connection parameters of the proxy server.</td>
</tr>
<tr>
<td>Relationship mapping for upsert</td>
<td>Click the [+] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module.</td>
</tr>
<tr>
<td></td>
<td>* Column name of Talend Schema:* the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the External id name column, which are the fields of the lookup module specified in the Module name column.</td>
</tr>
<tr>
<td></td>
<td>* Lookup field name:* the name of the lookup field. It refers to the lookup field of the module specified in the Module Name field in the Basic settings view. This column needs to be specified when there are NULL input values for it and the Ignore Null check box is cleared.</td>
</tr>
</tbody>
</table>
**Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the Basic settings view and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.
- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

This property is available only when **UPSERT** is selected from the **Output Action** drop-down list.

<table>
<thead>
<tr>
<th>Extend Insert</th>
<th>Select this check box to transfer the output data in batches. In the <strong>Commit Level</strong> field displayed, specify the number of lines per batch.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Die on Error</td>
<td>Select the check box to stop the execution of the Job when an error occurs. This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>
| Retrieve Id            | Select this check box to allow Salesforce to return the Salesforce ID for the inserted or updated records. This check box is available only when **INSERT** or **UPSERT** is selected from the **Output Action** drop-down list and the **Extend Insert** check box is cleared. When this check box is selected and the **tSalesforceOutput** component is linked to another component via a Row > Main connection, the following column(s) will be added to the schema of the data flow:
  - **salesforce_id**: the Salesforce ID of the created or updated record.
  - **salesforce_upsert_status** (only for **UPSERT**): the status of the upsert action to indicate whether the record is created or updated. |
| Ignore Null            | Select this check box to ignore NULL values. This property is available only when **UPDATE** or **UPSERT** is selected from the **Output Action** drop-down list. |
| Log File Name          | Specify the path to the log file that holds all error logs. |
| tStatCatcher Statistics| Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| **NB_LINE** | The number of rows processed. This is an After variable and it returns an integer. |
| **NB_SUCCESS** | The number of rows successfully processed. This is an After variable and it returns an integer. |
| **NB_REJECT** | The number of rows rejected. This is an After variable and it returns an integer. |
| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component can be used as an end component or an intermediate component of a Job or Subjob and it always needs an input link. |

**Upserting Salesforce data based on external IDs**

Here is an example of using Talend components to insert and update Salesforce Contact object data based on the mapping relationship with external IDs of the Account object.

The Job used in this example is composed of the following seven subjobs:

- the first subJob opens a connection to Salesforce,
- the second subJob deletes some Account records based on external IDs,
- the third subJob inserts two Account records with external IDs,
- the fourth subJob inserts three Contact records based on the mapping relationship with the Account object external IDs, and gathers both inserted and erroneous data,
- the fifth subJob updates two inserted Contact records based on the mapping relationship with the Account object external IDs,
- the sixth subJob retrieves the inserted Account records, and
- the seventh subJob retrieves the upserted Contact records.
Creating a Job for upserting Salesforce data based on external IDs

Before you begin

- An external ID custom field `Account_External_ID` has been added for the Account object in your Salesforce, which will be used to map the relationship with the Contact object.
An external ID custom field Contact_Talend_ID has been added for the Contact object in Salesforce, which will be used as the key column for upserting Contact object data.

Procedure

1. Create a new Job and add a tSalesforceConnection component, three tSalesforceInput components, four tSalesforceOutput components, three tFixedFlowInput components, and four tLogRow components.
2. Connect the first tSalesforceInput component to the first tSalesforceOutput component using a Row > Main connection.
3. Do the same to connect the first tFixedFlowInput component to the second tSalesforceOutput component, the second tFixedFlowInput component to the third tSalesforceOutput component, the third tFixedFlowInput component to the fourth tSalesforceOutput component, the second tSalesforceInput component to the third tLogRow component, and the third tSalesforceInput component to the fourth tLogRow component.
4. Connect the third tSalesforceOutput component to the first tLogRow component using a Row > Main connection and to the second tLogRow component using a Row > Reject connection.
5. Connect the tSalesforceConnection component to the first tSalesforceInput component using a Trigger > On Subjob Ok connection.
6. Do the same to connect the first tSalesforceInput component to the first tFixedFlowInput component, the first tFixedFlowInput component to the second tFixedFlowInput component, the second tFixedFlowInput component to the third tFixedFlowInput component, the third tFixedFlowInput component to the second tSalesforceInput component, and the second tSalesforceInput component to the third tSalesforceInput component.

Opening a connection to Salesforce

Procedure

1. Double-click the tSalesforceConnection component to open its Basic settings view on the Component tab.
2. Select Basic from the Connection type drop-down list to connect to Salesforce using your Salesforce account username, password, and security token.
   
   In this example, you connect to Salesforce using the basic connection type. You can also connect to Salesforce using the OAuth JWT (JSON Web Token) Flow type. For more information, see the related description of how to connect to Salesforce using OAuth JWT Flow on Talend Help Center (https://help.talend.com).
3. In the User Id field, enter your Salesforce username.
4. Click the [...] button next to the Password field and in the pop-up dialog box, enter your Salesforce password between double quotation marks.
5. Click the [...] button next to the **Security Token** field and in the pop-up dialog box, enter your Salesforce security token between double quotation marks.

You can use the Salesforce metadata wizard to create a connection to your Salesforce system, save the connection in the Repository, and then reuse the connection configuration defined in the metadata wizard in Salesforce components. For more information, see the related description of centralizing Salesforce metadata.

**Deleting Salesforce Account records based on external ID**

**Procedure**

1. Double-click the first **tSalesforceInput** component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object whose data will be deleted, **Account** in this example. The schema of the Account object will be automatically filled.
4. Click **OK** to save the changes and in the pop-up dialog box, click **Yes** to propagate the schema to the next **tSalesforceOutput** component.
5. Select **Query** from the **Query Mode** drop-down list and specify the condition used to filter data to be deleted. In this example, it is `talendlena__Account_External_ID__c like '%talend%'`.

All Salesforce Account records whose `talendlena__Account_External_ID__c` field contains `talend` will be deleted.

6. Double-click the first **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.
7. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
8. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object whose data will be deleted, **Account** in this example.
9. Select **DELETE** from the **Output Action** drop-down list to perform the delete operation on the Account objects filtered by the first **tSalesforceInput** component.

**Inserting Salesforce Account records with external IDs**

**Procedure**

1. Double-click the second **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Account** in this example. The schema of the Account object will be automatically filled.
4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the two columns **Name** and **talendlena__Account_External_ID__c**. Then click to copy these two columns to the first **tFixedFlowInput** component. When done, click **OK** to close the dialog box.

5. Select **INSERT** from the **Output Action** drop-down list.

6. Double-click the first **tFixedFlowInput** component to open its **Basic settings** view on the **Component** tab.

```
<table>
<thead>
<tr>
<th>Name</th>
<th>talendlena__Account_External_ID__c</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;account_talend&quot;</td>
<td>&quot;account_talend_exid&quot;</td>
</tr>
<tr>
<td>&quot;account_talend_doc&quot;</td>
<td>&quot;account_talend_doc_exid&quot;</td>
</tr>
</tbody>
</table>
```

7. In the **Mode** area, select **Use Inline Table** and in the table displayed, enter the data to be inserted into the Salesforce Accout object. In this example, the following two records will be inserted.

```
account_talend;account_talend_exid  
account_talend_doc;account_talend_doc_exid  
```

You can also select **Use Inline Content**, and then copy and paste the input data into the **Content** field displayed.

### Inserting Salesforce Contact records upon Account external IDs

#### Procedure

1. Double-click the third **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.

2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.

3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Contact** in this example. The schema of the Contact object will be automatically filled. When done, click **OK** to save the changes and in the pop-up dialog box, click **Yes** to propagate the schema to the next two **tLogRow** components.

4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the three columns **LastName**, **FirstName**, and **talendlena__Contact_Talend_ID__c**. Then add another column **Account_External_ID** of **String** type and copy these four columns to the second **tFixedFlowInput** component. When done, click **OK** to close
the dialog box and in the pop-up dialog box, click Yes to propagate the schema to the next two tLogRow components.

5. Select UPSERT from the Output Action drop-down list and talendlena__Contact_Talend_ID from the Upsert Key Column drop-down list displayed.

6. Go to the Advanced settings view and in the Relationship mapping for upsert table, specify the relationship mapping for the column Account_External_ID by adding one row and setting the value for each table column. In this example, the column Account_External_ID is mapped with the external ID field talendlena__Account_External_ID__c of the Account object, so the value for Column name of Talend Schema is Account_External_ID, the value for Lookup relationship field name and Module name is Account, and the value for External id name is talendlena__Account_External_ID__c.

7. Clear the Extend Insert and Die on Error check boxes so that erroneous data can be gathered via the Row > Reject connection.

8. Double-click the second tFixedSizeFlowInput component to open its Basic settings view on the Component tab.
9. In the Mode area, select Use Inline Table and in the table displayed, enter the data to be inserted into the Salesforce Contact object. In this example, the input data is as follows.

<table>
<thead>
<tr>
<th>Name</th>
<th>Last Name</th>
<th>ID</th>
</tr>
</thead>
<tbody>
<tr>
<td>Beckham;David</td>
<td>2018010001;account_talend_exid</td>
<td></td>
</tr>
<tr>
<td>Taylor;Swift</td>
<td>2018010002;account_talend_exid</td>
<td></td>
</tr>
<tr>
<td>;;</td>
<td>2018010003;account_talend_exid</td>
<td></td>
</tr>
</tbody>
</table>

You can also select Use Inline Content, and then copy and paste the input data into the Content field displayed.

10. Double-click the first tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

11. Do the same to configure the second tLogRow component.

**Updating Salesforce Contact records upon Account external IDs**

**Procedure**

1. Double-click the fourth tSalesforceOutput component to open its Basic settings view on the Component tab.
2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object into which data will be inserted, Contact in this example. The schema of the Contact object will be automatically filled.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns Phone, Email, and talendlena__Contact_Talend_ID__c. Then add another column Account_External_ID of String type and copy these four columns to the second tFixedFlowInput component. When done, click OK to close the dialog box.
5. Select UPSERT from the Output Action drop-down list and talendlena__Contact_Talend_ID__c from the Upsert Key Column drop-down list displayed.
6. Go to the Advanced settings view and in the Relationship mapping for upsert table, specify the relationship mapping for the column Account_External_ID by adding one row and setting the value for each table column. In this example, the column Account_External_ID is mapped with the external ID field talendlena__Account_External_ID__c of the Account object, so the value for Column name of Talend Schema is Account_External_ID, the value for Lookup relationship field name and Module name is Account, and the value for External id name is talendlena__Account_External_ID__c.
7. Double-click the third tFixedFlowInput component to open its Basic settings view on the Component tab.
8. In the Mode area, select Use Inline Table and in the table displayed, enter the data used to update the two records inserted into the Salesforce Contact object. In this example, the updated data is as follows. The phone and email values will be added for both two records and the Account external ID value for the second record is updated to `account_talend_doc_exid`.

```
+86 13666666666;beckham.david@talend.com;2018010001;account_talend_exid
+86 13888888888;taylor.swift@talend.com;2018010002;account_talend_doc_exid
```

You can also select Use Inline Content, and then copy and paste the input data into the Content field displayed.

**Retrieving inserted Salesforce Account records**

**Procedure**

1. Double-click the second tSalesforceInput component to open its Basic settings view on the Component tab.
2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object from which data will be retrieved, Account in this example. The schema of the Account object will be automatically filled.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns Id, Name, and `talendlena__Account_External_ID__c`. When done, click OK to save the changes and in the pop-up dialog box, click Yes to propagate the schema to the next tLogRow component.
5. Select Query from the Query Mode drop-down list and specify the condition used to filter data to be retrieved. In this example, it is Name like '%talend%'.

All Salesforce Account records whose Name field contains `talend` will be retrieved.
6. Double-click the third tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

**Retrieving updated Salesforce Contact records using SOQL query**
Procedure

1. Double-click the third tSalesforceInput component to open its Basic settings view on the Component tab.

2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.

3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object from which data will be retrieved, Contact in this example. The schema of the Contact object will be automatically filled.

4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the four columns Name, Phone, Email, and talendlena__Contact_Talend_ID__c.

5. Add another two columns to retrieve name and external ID of the linked Account object, Contact_Account_Name and Contact_Account_talendlena__Account_External_ID__c in this example.

   To retrieve data of a linked object column, it is necessary to define the name of the column in a particular manner in the schema editor. The correct syntax is NameofCurrentObject_NameofLinkedObject_NameofColumnofInterest. If this syntax is not respected, data from the linked object will not be returned. For more information about how to set schema for the relationship query, see How to set schema for the guess query feature of tSalesforceInput on page 3374.

6. Click OK to save the changes. In the pop-up dialog box, click Yes to propagate the schema to the next tLogRow component.

7. Select Query from the Query Mode drop-down list.

8. Select the Manual Query check box and click the Guess query button to generate the SOQL query based on the defined module name and schema columns. The generated SOQL query will look like below.

   SELECT Name, Phone, Email, talendlena__Contact_Talend_ID__c, Contact.Account.Name, Contact_Account_talendlena__Account_External_ID__c FROM Contact

9. In the generated SOQL query string, replace each underscore character after the object name in the column name Contact_Account_talendlena__Account_External_ID__c with a dot character. Then add the WHERE condition clause used to filter data to be retrieved at the end of the generated SOQL query. In this example, it is talendlena__Contact_Talend_I
D__c like '201801%' and all Salesforce Contact records whose talendlena__Contact_Talend_ID__c field begins with 201801 will be retrieved. The updated SOQL query will look like below.

```
SELECT Name, Phone, Email, talendlena__Contact_Talend_ID__c, Contact.Account.Name, Contact.Account.talendlena__Account_External_ID__c FROM Contact WHERE talendlena__Contact_Talend_ID__c like '201801%'
```

10. Double-click the fourth tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

**Executing the Job to upsert Salesforce data based on external ID**

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to execute your Job.

As shown above, two Account records account_talend and account_talend_doc are successfully inserted, two Contact records Beckham David and Taylor Swift are successfully inserted and updated based on the mapping relationship with the external IDs in the Account object, and another Contact record missing the value for the required field LastName is not inserted.

You can also go to the Salesforce website to double-check the Job execution result.
<table>

</table>
tSalesforceOutputBulk

Generates the file to be processed by the tSalesforceBulkExec component for bulk processing.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

tSalesforceOutputBulk Standard properties

These properties are used to configure tSalesforceOutputBulk running in the Standard Job framework. The Standard tSalesforceOutputBulk component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
<table>
<thead>
<tr>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td>Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
<td></td>
<td></td>
</tr>
<tr>
<td>Bulk File Path</td>
<td>Specify the path to the file to be generated.</td>
<td>Append</td>
<td>Select this check box to append new data at the end of the file if it already exists, instead of overwriting the existing data.</td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Ignore Null</td>
<td>Select this check box to ignore NULL values.</td>
<td></td>
<td></td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

Advanced settings

| Relationship mapping for upsert | Click the [+] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module. |

3396
- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view of the **tSalesforceBulkExec** component and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.

- **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search **polymorphic** at [http://www.salesforce.com/us/developer/docs/api_asynch/](http://www.salesforce.com/us/developer/docs/api_asynch/).

- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

### tStatCatcher Statistics

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>

</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with the <strong>tSalesforceBulkExec</strong> component. Used together, they gain performance while feeding or modifying information in Salesforce.com.</th>
</tr>
</thead>
</table>

### Related scenario

No scenario is available for this component yet.
tSalesforceOutputBulkExec

Bulk-loads data in a given file into a Salesforce object.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

tSalesforceOutputBulkExec Standard properties

These properties are used to configure tSalesforceOutputBulkExec running in the Standard Job framework.

The Standard tSalesforceOutputBulkExec component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Select the way the connection details will be set.</th>

<td>The unique name of the certificate signed by Salesforce. This property is available only when the OAuth Json Web Token Flow type is selected.</td>
</tr>
<tr>
<td>Client Id</td>
<td>The OAuth Consumer Key, generated when your connected app is created and shown in the connected app detail page.</td>
</tr>
</tbody>
</table>
| **Client Secret** | The OAuth Consumer Secret, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see Create a Connected App.
This property is available only when the OAuth Implicit Flow type is selected. |
| **Callback Host** | The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.
This property is available only when the OAuth Implicit Flow type is selected. |
| **Callback Port** | The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.
This property is available only when the OAuth Implicit Flow type is selected. |
| **Token File** | The path to the token file that stores the refresh token used to get the access token without authorization.
This property is available only when the OAuth Implicit Flow type is selected. |
| **Module Name** | Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component connected in the Job. |
Output Action

Select one of the following operations to be performed from the drop-down list.

- **INSERT**: insert one or more new records into Salesforce.
- **UPDATE**: update one or more existing records in Salesforce.
- **UPSERT**: create new records and update existing records. In the Upsert Key Column field displayed, specify the key column for the upsert operation.
- **DELETE**: delete one or more records in Salesforce.

Bulk File Path

Specify the path to the file that stores the data to be processed.

Append

Select this check box to append new data at the end of the file if it already exists, instead of overwriting the existing data.

Ignore Null

Select this check box to ignore NULL values.

### Advanced settings

**Salesforce URL**

The Webservice URL required to connect to Salesforce.

**API version**

The Salesforce API version. This property is available only when the OAuth connection type is selected.

**Need compression**

Select this check box to activate SOAP message compression, which can result in increased performance levels.

**Trace HTTP message**

Select this check box to output the HTTP interactions on the console.

**Client Id**

Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website.

**Timeout**

Enter the intended number of query timeout in milliseconds in Salesforce.

**Use Proxy**

Select this check box to use a proxy server, and in the **Host**, **Port**, **User Id**, and **Password** fields displayed, specify the connection parameters of the proxy server.

**Bulk API V2**

Select this checkbox to create a Bulk API V2 job, and then select a type of field delimiter from the **Column Delimiter** drop-down list and a way of line ending from the **Line Ending** drop-down list respectively for CSV data. Compared with Bulk API V1, Bulk API v2 simplifies the way of processing data. This property is available only when the OAuth connection type is selected.

**Relationship mapping for upsert**

Click the [+] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship
fields in the upsert module, the lookup module as well as the external ID fields in the lookup module.

- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

- **Module name**: the name of the lookup module.

- **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search polymorphic at [http://www.salesforce.com/us/developer/docs/api_asynch/](http://www.salesforce.com/us/developer/docs/api_asynch/).

- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

This property is available only when **UPSERT** is selected from the **Output Action** drop-down list.

Inserting bulk data into Salesforce

This scenario describes a four-component Job that bulk-loads data in a file into Salesforce, performs the intended action on the data, and ends up with displaying the Job execution results on the console.

The content of the input file `SalesforceAccount.txt` used in this example is as follows:

```
Name;ParentId;Phone;Fax
Burlington Textiles Corp of America;;(336) 222-7000;(336) 222-8000
Dickenson plc;; (785) 241-6200;(785) 241-6201
GenePoint;;(650) 867-3450;(650) 867-9895
Edge Communications;talend;(512) 757-6000;(512) 757-9000
Grand Hotels & Resorts Ltd;talend;(312) 596-1000;(312) 596-1500
```

Setting up the Job for inserting bulk data into Salesforce

Procedure

1. Create a new Job and add a `tFileInputDelimited` component, a `tSalesforceOutputBulkExec` component, and two `tLogRow` components by typing their names on the design workspace or dropping them from the Palette.
2. Link the `tFileInputDelimited` component to the `tSalesforceOutputBulkExec` component using a Row > Main connection.
3. Link the `tSalesforceOutputBulkExec` component to the first `tLogRow` component using a Row > Main connection.
4. Link the `tSalesforceOutputBulkExec` component to the second `tLogRow` component using a Row > Reject connection.
Configuring the Job for inserting bulk data into Salesforce

Procedure

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.

   ![tFileInputDelimited_1 settings](image)

   - **Property Type**: Built-In
   - **File name/Stream**: D:/SalesforceAccount.txt
   - **Row Separator**: \n
   2. In the **File name/Stream** field, browse to or enter the path to the input data file. In this example, it is D:/SalesforceAccount.txt.

3. Click the [...] button next to **Edit schema** and in the pop-up schema dialog box, define the schema by adding four columns Name, ParentId, Phone and Fax of String type. When done, click **OK** to save the changes and close the dialog box.

   ![Scheme of tFileInputDelimited_1](image)

4. Double-click the **tSalesforceOutputBulkExec** component to open its **Basic settings** view.
5. In the **User Id**, **Password** and **Security Key** fields, enter the user authentication information required to access Salesforce.

6. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object you want to access. In this example, it is **Account**.

7. In the **Bulk File Path** field, browse to or enter the path to the CSV file that stores the data for bulk processing. The bulk file to be processed must be in csv format.

8. Double-click the first **tLogRow** component to open its **Basic settings** view.

9. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the results.

10. Do the same to configure the second **tLogRow** component.

### Executing the Job to insert bulk data into Salesforce

#### Procedure

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to execute the Job.

On the console of the **Run** view, you can check the execution result.
In the tLogRow_1 table, you can read the data inserted into Salesforce.

In the tLogRow_2 table, you can read the rejected data due to the incompatibility with the Account objects you have accessed.

Note that if you want to transform the input data before loading them into Salesforce, you need to use tSalesforceOutputBulk and tSalesforceBulkExec in cooperation to achieve this purpose.
tSalesforceEinsteinBulkExec

Loads data into Salesforce Analytics Cloud from a local file.

**tSalesforceEinsteinBulkExec Standard properties**

These properties are used to configure `tSalesforceEinsteinBulkExec` running in the Standard Job framework.

The Standard `tSalesforceEinsteinBulkExec` component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository:</td>
<td>Select the repository file in which the properties are stored. The connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

**User Name and Password**

Enter the Web service authentication details.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**End Point**

Enter the WebService URL required to connect to Salesforce. For example, `https://login.salesforce.com/services/Soap/u/37.0`. Note that the version in the URL should be 32.0 or later.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- For the fields of numeric type (for example, byte, short, int, long, float, double, and BigDecimal), their length and precision values need to be specified. The default length and precision values are 10 and 2, and you can also specify their custom values in the schema editor.
- For the fields of date type, you need to specify the format of the date in the schema editor. For more information about the supported date format, see Analytics Cloud External Data Format Reference.
The **Schema** list and the **Editor schema** button disappear if the **Custom JSON Metadata** check box is selected.

| **Built-In:** | You create and store the schema locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository:** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see *Talend Studio User Guide*. |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Operation

Select an operation to perform on the dataset:

- **Append**: Append all data to the dataset. Create a dataset if it does not exist.
- **Upsert**: Insert or update rows in the dataset. Create a dataset if it does not exist.
- **Overwrite**: Create a new dataset with the given data, and replace dataset if it already exists.
- **Delete**: Delete the rows from the dataset.

**Note:**

- A metadata JSON file is required for the **Append**, **Upsert**, and **Delete** operations.
- The data and metadata for the **Append** and **Upsert** operations must match the dataset on which the operation is happening. All columns, dimensions, and measures must match exactly.
- The **Append** operation is not allowed if you specify any column as the primary key.
- You must specify one (and only one) column as the primary key on which the **Upsert** or **Delete** operation is based. You can do that by clicking **Edit schema** and selecting the check box next to the column you want to set as the primary key.
- The metadata for the **Delete** operation must be a subset of the dataset columns.

### Name

Type in the name of the dataset into which the data will be loaded.

### CSV File

Specify the path to the local CSV file to be loaded.
## Advanced settings

| **CSV Encoding** | Enter the encoding type of the CSV file.  
This field is not visible when the Custom JSON Metadata check box is selected. |
|------------------|----------------------------------------------------------------------------------------------------------------------------------|
| **Fields Delimiter** | Enter the character that separates the field values in the CSV file.  
This field is not visible when the Custom JSON Metadata check box is selected. |
| **Fields Enclosed By** | Enter the character used to enclose the field values in the CSV file.  
This field is not visible when the Custom JSON Metadata check box is selected. |
| **Line Terminated By** | Enter the character indicating the end of a line.  
This field is not visible when the Custom JSON Metadata check box is selected. |
| **Auto Generate JSON Metadata Description** | Select this check box to generate the JSON metadata description automatically. |
| **Header** | Specify the number of lines to ignore in the CSV file.  
This field is available only when the Auto Generate JSON Metadata Description check box is cleared. |
| **Unique API Name** | Specify the unique API name for the object in the JSON metadata description.  
This field is available only when the Auto Generate JSON Metadata Description check box is cleared. |
| **Label** | Specify the display name for the object in the JSON metadata description.  
This field is available only when the Auto Generate JSON Metadata Description check box is cleared. |
| **Fully Qualified Name** | Specify the full path that uniquely identifies the record in the JSON metadata description.  
This field is available only when the Auto Generate JSON Metadata Description check box is cleared. |
| **Custom JSON Metadata** | Select this check box to use a customized JSON metadata file.  
This check box is available only when the Auto Generate JSON Metadata Description check box is cleared. |
| **JSON Metadata** | Specify the path to the customized JSON metadata file.  
This field is available only when the Custom JSON Metadata check box is selected. |
| **Generate JSON in File** | Select this check box to write the JSON metadata description into a local file.  
This check box is not visible when the Custom JSON Metadata check box is selected. |
**Generated JSON Folder**

Specify the directory where you want to store the generated JSON metadata file. This field is available only when the **Generate JSON in File** check box is selected.

**Retrieve Upload Status**

Select this check box to retrieve the status of the data upload.

**Time to wait for server answer (seconds)**

Specify the amount of time in seconds to wait for the upload status response from the server. This field is available only when the **Retrieve Upload Status** check box is selected.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string.

### Usage

**Usage rule**

This component can be used as a standalone component.

### Related scenario

No scenario is available for this component yet.
tSalesforceEinsteinOutputBulkExec

Gains in performance during data operations to the Salesforce Analytics Cloud.
tSalesforceEinsteinOutputBulkExec receives data from the preceding component, generates a local CSV file and then loads data from the file to the Salesforce Analytics Cloud.

**tSalesforceEinsteinOutputBulkExec Standard properties**

These properties are used to configure tSalesforceEinsteinOutputBulkExec running in the Standard Job framework.

The Standard tSalesforceEinsteinOutputBulkExec component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

**User Name and Password**

Enter the Web service authentication details.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**End Point**

Enter the WebService URL required to connect to Salesforce. For example, https://login.salesforce.com/services/Soap/u/37.0. Note that the version in the URL should be 32.0 or later.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- For the fields of numeric type (for example, byte, short, int, long, float, double, and BigDecimal), their length and precision values need to be specified. The default length and precision values are 10 and 2, and you can also specify their custom values in the schema editor.
- For the fields of date type, you need to specify the format of the date in the schema editor. For more
information about the supported date format, see Analytics Cloud External Data Format Reference. The Schema list and the Editor schema button disappear if the Custom JSON Metadata check box is selected.

<table>
<thead>
<tr>
<th>Built-In: You create and store the schema locally for this component only. Related topic: see Talend Studio User Guide.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. Related topic: see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Click Sync columns to retrieve the schema from the previous component connected in the Job.

**Operation**

Select an operation to perform on the dataset:

- **Append**: Append all data to the dataset. Create a dataset if it does not exist.
- **Upsert**: Insert or update rows in the dataset. Create a dataset if it does not exist.
- **Overwrite**: Create a new dataset with the given data, and replace dataset if it already exists.
- **Delete**: Delete the rows from the dataset.

**Note:**

- A metadata JSON file is required for the Append, Upsert, and Delete operations.
- The data and metadata for the Append and Upsert operations must match the dataset on which the operation is happening. All columns, dimensions, and measures must match exactly.
- The Append operation is not allowed if you specify any column as the primary key.
- You must specify one (and only one) column as the primary key on which the Upsert or Delete operation is based. You can do that by clicking Edit schema and selecting the check box next to the column you want to set as the primary key.
- The metadata for the Delete operation must be a subset of the dataset columns.

</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>
Usage

| Usage rule | This component is mainly used when no particular transformation is required on the data to be loaded to Salesforce Analytics Cloud. |

Related scenario

For a similar scenario, see Inserting bulk data into Salesforce on page 3403.
tSampleRow

Selects rows according to a list of single lines and/or a list of groups of lines.

**tSampleRow Standard properties**

These properties are used to configure tSampleRow running in the Standard Job framework.

The Standard tSampleRow component belongs to the Processing family.

The component in this framework is available in all Talend products.

### Basic settings

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
  
Click **Sync columns** to retrieve the schema from the previous component in the Job. |

| **Built-in**: You create the schema and store it locally for the relevant component. Related topic: see *Talend Studio User Guide*. |

| **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see *Talend Studio User Guide*. |

| **Range** | Enter a range using the relevant syntax to choose a list of single lines and/or a list of groups of lines. |

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |

| **Global Variables** |  

3416
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component handles flows of data therefore it requires input and output components. |
