3. Connect tMomInput to tLogRow using a Row > Main link to form the second subJob. This subJob will fetch the XML files from MOM queue and display the file contents on the console.
4. Connect tFileInputXML to tMomInput using a Trigger > On Component Ok connection to link the two subjobs.

**Configuring the first subJob**

**Configuring the input components**

**Procedure**

1. Double-click the tFileList component to open its Basic settings view.

   ![tFileList component](image)

   - In the Directory field, enter the path to the directory to read XML files from, or browse to the path by clicking the [...] button next to the field.
   - Select **Use Glob Expressions as Filemask** check box, add a new line in the Files field by clicking the [+ ] button, and enter "*.xml" as the file mask so that all XML files in the directory will be used. Keep all the other settings as they are.

2. Double-click the tFileInputXML component to open its Basic settings view.
5. Click the [...] button next to Edit schema to open the Schema dialog box.

6. Click the [+] button to add a column, give it a name, message in this example, and select Document from the Type list to handle XML format files. Then, click OK to close the dialog box.

7. In the File name/Stream field, press Ctrl+Space to access the global variable list, and select tFileList_1.CURRENT_FILEPATH to loop on the context files’ directory.

8. In the Loop XPath query fields, enter "/" to define the root as the loop node of the input files’ structure; in the Mapping table, fill the XPath query column with "." to extract all data from context node of the source files, and select the Get Nodes check box to build a Document type data flow.

Configuring the tMomOutput component

Procedure

1. Double-click the tMomOutput component to open its Basic settings view.
2. Select **WebSphere MQ** from the **MQ server** list, and enter the host name or IP address of the MQ server and the port number.

3. Enter the login authentication information in the **Username** and **Password** fields, and enter the channel name of the transmission queue in the **Channel** field.

4. As we are handling file messages, select **Text Message** from the **Message Body Type** list.

5. Click **Sync columns** to retrieve the schema structure from the preceding component.

6. Fill in the queue manager and message queue details in the corresponding fields, and leave the other settings as they are.

**Configuring the second subJob**

**Procedure**

1. Double-click the **tMomInput** component to open its **Basic settings** view.

2. Set the basic parameters of the component using the same settings you have done in the **tMomOutput** component, including the MQ server details, login authentication details, channel, message body type, queue manager and message queue.

3. Click the [...] button next to **Edit schema** to open the **Schema** dialog box.
4. From the **Type** list for the **message** column, select **Document** to handle XML format files, and then click **OK** to close the dialog box.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

   The XML files in the specified folder are written to the message queue and then retrieved from the queue. The contents of the files are displayed on the console.

**tMomMessageIdList**

Fetches a message ID list from a queue on a Message-Oriented middleware system and passes it to the next component.

tMomMessageIdList makes it possible to iterate on certain message IDs. It is usually used with tMomInput, for more information, see **tMomInput Standard properties** on page 2240.

**tMomMessageIdList Standard properties**

These properties are used to configure tMomMessageIdList running in the Standard Job framework. The Standard tMomMessageIdList component belongs to the Internet family. The component in this framework is available in all **Talend products**.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and from the list displayed select the relevant connection component to reuse the connection details you have already defined. When a Job contains a parent Job and a child Job, the list displayed presents only the connection components in the same Job level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>MQ Server</td>
<td>Select the MOM server to be used from the list. According to the server selected, the parameters required differ slightly.</td>
</tr>
<tr>
<td>Host/Port</td>
<td>Fill in the Host name or IP address of the MOM server and Port.</td>
</tr>
<tr>
<td>Channel</td>
<td>Channel on the queue.</td>
</tr>
<tr>
<td>Queue Manager</td>
<td>Fill in the server driver details.</td>
</tr>
<tr>
<td>Message Queue</td>
<td>Source of the message.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|-------------------|**CURRENT_MESSAGE_ID**: the identifier of the current message. This is a Flow variable and it returns a string. |
|                   |**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>

</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Make sure the relevant Websphere server is launched.</td>
</tr>
<tr>
<td></td>
<td>This component requires installation of its related jar files.</td>
</tr>
</tbody>
</table>

Related scenario

For a related scenario, see tMomInput on page 2240.
# tMomOutput

Adds a message to a Message-Oriented Middleware system queue in order for it to be fetched asynchronously.

`tMomOutput` makes it possible to set up asynchronous communications via a MOM server.

For further information, see the section about messaging brokers supported by Talend messaging components in *Talend Data Fabric Studio User Guide*.

## tMomOutput Standard properties

These properties are used to configure `tMomOutput` running in the Standard Job framework.

The Standard `tMomOutput` component belongs to the Internet family.

The component in this framework is available in all *Talend products*.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td><strong>Failover</strong></td>
<td>Select this check box to use the ActiveMQ failover transport. For more information about the failover transport, see Failover Transport Reference. This check box is available only when ActiveMQ is selected from the MQ server list and the Static Discovery check box is cleared.</td>
</tr>
<tr>
<td><strong>Static Discovery</strong></td>
<td>Select this check box to use the ActiveMQ static transport discovery mechanism. For more information about the static transport, see Static Transport Reference. This check box is available only when ActiveMQ is selected from the MQ server list and the Failover check box is cleared.</td>
</tr>
<tr>
<td><strong>URI parameters</strong></td>
<td>Enter the URI parameters. This field is available only when the Failover or Static Discovery check box is selected.</td>
</tr>
<tr>
<td><strong>MQ Server</strong></td>
<td>Select the type of the MQ server(s) to be connected from the list: ActiveMQ, JBoss Messaging, or WebSphere MQ. According to the server type selected, the parameters required differ slightly.</td>
</tr>
<tr>
<td><strong>Use SSL Transport</strong></td>
<td>Select this check box to use the ActiveMQ SSL transport. For more information about the SSL transport, see SSL Transport Reference. This check box is available only when ActiveMQ is selected from the MQ server list.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Enter the host name or IP address of the MQ server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Enter the listening port of the MQ server.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication credentials. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Channel</strong></td>
<td>Specify the name of the channel through which the connection is established. The default value is <strong>DC.SVRCONN</strong>. This field is available only when <strong>WebSphere MQ</strong> is selected from the <strong>MQ server</strong> list.</td>
</tr>
<tr>
<td><strong>To</strong></td>
<td>Type in the message destination, respecting the syntax required by the server; this must include the type and name of the target folder, e.g.: queue/A or topic/testtopic. Note that this field is case-sensitive. This field is available only when <strong>ActiveMQ</strong> or <strong>JBoss Messaging</strong> is selected from the <strong>MQ Server</strong> list.</td>
</tr>
<tr>
<td><strong>Message Type</strong></td>
<td>Select the message type: either <strong>Topic</strong> or <strong>Queue</strong>. This list is available only when <strong>ActiveMQ</strong> or <strong>JBoss Messaging</strong> is selected from the <strong>MQ Server</strong> list.</td>
</tr>
<tr>
<td><strong>Message Body Type</strong></td>
<td>Select the message body type: <strong>Text Message</strong>, <strong>Bytes Message</strong> or <strong>Map Message</strong>.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. In the context of <strong>tMomOutput</strong> usage, the schema is read-only but will change according to the incoming schema. Only one-column schema is expected by the server to contain the <strong>Messages</strong>.</td>
</tr>
<tr>
<td><strong>QueueManager</strong></td>
<td>Specify the name of the queue manager to which the connection is established. This field is available only when <strong>WebSphere MQ</strong> is selected from the <strong>MQ server</strong> list.</td>
</tr>
<tr>
<td><strong>MessageQueue</strong></td>
<td>Enter the name of the message queue into which message queueing applications can put messages. This field is available only when <strong>WebSphere MQ</strong> is selected from the <strong>MQ server</strong> list.</td>
</tr>
<tr>
<td><strong>Set Transacted</strong></td>
<td>Select this check box to transact the session. For further information about this parameter, see <a href="https://publib.boulder.ibm.com/series/v5r2/ic2924/books/csqqzaw07.pdf">https://publib.boulder.ibm.com/series/v5r2/ic2924/books/csqqzaw07.pdf</a>. Note that selecting this check box will ignore the settings in the Acknowledgement Mode list in the Advanced settings view of tMomInput.</td>
</tr>
<tr>
<td><strong>Is using message id to set</strong></td>
<td>Select this check box to set messages according to their ids.</td>
</tr>
</tbody>
</table>
Advanced settings

### Additional options

Define the additional transport options in the table. This table is available only if you select the Failover or Static Discovery check box in the Basic settings view.

- **Option name**: the name of the option.
- **Option value**: the value of the option.

For example, enter `maxReconnectAttempts` in the **Option name** field and then `0` in the **Option value** field so that no attempt is made to retry the connection when no server is available.

For more information about the failover transport options, see Failover Transport Reference.

For more information about the static discovery transport options, see Static Transport Reference.

### Delivery Mode

Select a delivery mode supported by JMS:

- **Not Persistent**: This delivery mode does not require that the message be logged to stable storage.
- **Persistent**: This delivery mode requires that the message be logged to stable storage as part of the client’s send operation.

For further information about the delivery modes, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.

(Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.)

### Set Jms Header

Select this check box to send the Jms headers through the mapping from Jms fields onto MQ Series fields on the MQ server. When this check box is checked, you can specify the header name and the header value in the line(s) you added by clicking the plus button in the Parameters table. For further information about the usage of Jms headers, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.

(Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.)

### Set Jms Properties

Select this check box to send the Jms properties mapped onto MQMD fields on the MQ server. When this check box is checked, you can specify the property name, the property type and the property value in the line(s) you added by clicking the plus button in the Parameters table. For further information about the usage of Jms properties, see https://publib.boulder.ibm.com/iseries/v5r2/ic2924/books/csqzaw07.pdf.

(Available when ActiveMQ or JBoss Messaging is selected in the MQ Server list.)

### Use format

Select this check box to specify the WebSphere message format in the WebSphere Message Format field. The default format is MQSTR.

(Available when **WebSphere MQ** is selected in the **MQ Server** list.)

### Set MQMD Fields

Select this check box to enable the **Parameters** table in which you can specify the value of the MQMD fields. This check box is available only when **WebSphere MQ** is selected from the **MQ Server** list.

### Parameters

Specify the value of the MQMD fields.

- **Field Name**: Select an MQMD field from the list.
- **Field Value**: Enter the value of the corresponding MQMD field.

This table is available only when the **Set MQMD Fields** check box is selected.

For more information about the MQMD fields, see [Fields for MQMD](http://publib.boulder.ibm.com/infocenter/wmbhelp/v6r1m0/index.jsp?topic=%2Fcom.ibm.etools.mft.doc%2Faq06920_.htm).

### Include Header

Select this check box to specify the header of the message:

- **MQRFH2 fixed Portion**: Select this check box and click the plus button to add one or more lines to specify the Version, Encoding, Format, Flags, NameValueCCSID and CodedCharSetId as needed for the fixed portion of MQRFH2 header.
- **MCD folder**: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the properties that describe the format of the message.
- **JMS folder**: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the transportation of JMS header fields and JMSX properties.
- **USR folder**: Select this check box and click the plus button to add one or more lines to specify the field name and the value for the transportation of application-defined properties associated with the message.

Available when **WebSphere MQ** is selected in the **MQ Server** list.

### Set Cipher Suite

Select this check box to enable the Cipher Suite list from which you can specify the Cipher Suite to be used with WebSphere MQ SSL.

For further information about Cipher Suite, see [CipherSpecs](http://publib.boulder.ibm.com/infocenter/wmbhelp/v6r1m0/index.jsp?topic=%2Fcom.ibm.etools.mft.doc%2Faq06920_.htm) and their equivalent CipherSuites supported by IBM WebSphere MQ.

Available when **WebSphere MQ** is selected in the **MQ Server** list.
### Custom Cipher Suite

Select this check box to allow you to customize Cipher Suite.

**IBM Cipher Mappings**: Use the IBM Java Cipher Suite to IBM MQ Cipher Spec Mappings.

**Oracle Cipher Mappings**: Use the Oracle Cipher Suite to IBM MQ Cipher Spec Mappings.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

### Global Variables

#### Global Variables

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

#### Usage rule

This component must be linked to an input or intermediary component.

#### Dynamic settings

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your MQ Server connection dynamically from multiple connections planned in your Job.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2446 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 497. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

#### Limitation

Make sure the relevant WebSphere MQ, JBoss Messaging or ActiveMQ server is launched.

This component requires installation of its related jar files.
Related scenario

For a related scenario, see tMomInput on page 2240.
tMomRollback

Cancels the transaction committed in the MQ Server.

**tMomRollback Standard properties**

These properties are used to configure tMomRollback running in the Standard Job framework.
The Standard tMomRollback component belongs to the Internet family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>Select the component used in your Job.</th>
</tr>
</thead>
</table>
| Backout messages to backout queue (WebsphereMQ) | Select this check box to backout the messages to the backout queue defined in the Websphere MQ manager when the backout count reaches the configured threshold which is a property of the queue in the Websphere MQ server.  
  - If a tMomConnection component is selected from Component List, the messages processed by all tMomInput components that reuses the connection created by the selected tMomConnection component will be backouted.  
  - If a tMomInput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomInput component is cleared, the messages processed by the selected tMomInput component will be backouted.  
  - If a tMomInput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomInput component is selected, the messages processed by all tMomInput components that reuses the same connection the selected tMomInput component reused will be backouted.  
  - If a tMomOutput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomOutput component is cleared, no messages will be backouted.  
  - If a tMomOutput component is selected from Component List and the Use existing connection check box in the Basic settings view of the tMomOutput component is selected, the messages processed by all tMomInput components that reuses the same connection the selected tMomOutput component reused will be backouted.  

Note that this check box works only when the Commit (delete message after read from the queue), Backout messages to input queue, Backout messages to backout queue (when backoutCount of message reach the threshold value), and Browse message check boxes of all tMomInput components in the same Job are cleared.
**Close Connection**

Clear this check box to continue to use the selected connection once the component has performed its task.

**Related scenario**

For a similar scenario, see [Rollback from inserting data in mother/daughter tables](https://docs.talend.com) on page 2429.
tMondrianInput

Executes a multi-dimensional expression (MDX) query corresponding to the dataset structure and schema definition.

tMondrianInput reads data from relational databases and produces multidimensional data sets based on an MDX query. Then it passes on the multidimensional dataset to the next component via a Main row link.

**tMondrianInput Standard properties**

These properties are used to configure tMondrianInput running in the Standard Job framework. The Standard tMondrianInput component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Mondrian Version</td>
<td>Select the Mondrian version you are using.</td>
</tr>
<tr>
<td>DB type</td>
<td>Select the relevant type of relational database</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Datasource</td>
<td>Name and path of the file containing the data.</td>
</tr>
</tbody>
</table>
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- View schema: choose this option to view the schema only.  
- Change to built-in property: choose this option to change the schema to Built-in for local changes.  
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon... |
completion and choose this schema metadata again in the **Repository Content** window.

| **Built-in** | The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |

**Catalog**  
Path to the catalog (structure of the data warehouse).

**MDX Query**  
Type in the MDX query paying particularly attention to properly sequence the fields in order to match the schema definition and the data warehouse structure.

**Encoding**  
Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is a Flow variable and it returns an integer.  
**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| **Usage rule** | This component covers MDX queries for multi-dimensional datasets. |
| **Limitation** | This component requires installation of its related jar files. |
Extracting multi-dimensional datasets from a MySQL database (Cross-join tables)

This Job extracts multi-dimensional datasets from relational database tables stored in a MySQL base. The data are retrieved using a multidimensional expression (MDX query). Obviously you need to have to know the structure of your data, or at least have a structure description (catalog) as a reference for the dataset to be retrieved in the various dimensions.

Setting up the Job

Procedure

1. Drop tMondrianInput and tLogRow from the Palette to the design workspace.
2. Connect the Mondrian connector to the output component using a Row Main connection.

Setting up the DB connection

Procedure

1. Double-click the tMondrianInput component to display its Basic settings view.

   - In DB type field, select the relational database you are using with Mondrian.
   - Select the relevant Repository entry as Property type, if you store your DB connection details centrally. In this example the properties are built-in.
   - Fill out the details of connection to your DB: Host, Port, Database name, User Name and Password.
   - Select the relevant Schema in the Repository if you store it centrally. In this example, the schema is to be set (built-in).
Configuring the DB query

Procedure

1. The relational database we want to query contains five columns: `media`, `drink`, `unit_sales`, `store_cost` and `store_sales`.

2. The query aims at retrieving the `unit_sales`, `store_cost` and `store_sales` figures for various `media` / `drink` using an MDX query such as in the example below:

   **CrossJoin Example 1**

   The current slicer is 1997.

<table>
<thead>
<tr>
<th></th>
<th>Unit Sales</th>
<th>Store Cost</th>
<th>Store Sales</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Radio</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Alcoholic Beverages</td>
<td>75</td>
<td>70.40</td>
<td>160.62</td>
</tr>
<tr>
<td>Beverages</td>
<td>97</td>
<td>75.77</td>
<td>136.03</td>
</tr>
<tr>
<td>Dairy</td>
<td>54</td>
<td>36.75</td>
<td>39.03</td>
</tr>
<tr>
<td><strong>TV</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Alcoholic Beverages</td>
<td>76</td>
<td>70.99</td>
<td>132.38</td>
</tr>
<tr>
<td>Beverages</td>
<td>188</td>
<td>167.00</td>
<td>419.14</td>
</tr>
<tr>
<td>Dairy</td>
<td>68</td>
<td>45.19</td>
<td>119.55</td>
</tr>
<tr>
<td><strong>Sunday Paper</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Alcoholic Beverages</td>
<td>148</td>
<td>128.97</td>
<td>316.88</td>
</tr>
<tr>
<td>Beverages</td>
<td>197</td>
<td>161.81</td>
<td>399.58</td>
</tr>
<tr>
<td>Dairy</td>
<td>85</td>
<td>54.75</td>
<td>140.27</td>
</tr>
<tr>
<td><strong>Street Handout</strong></td>
<td></td>
<td></td>
<td></td>
</tr>
<tr>
<td>Alcoholic Beverages</td>
<td>158</td>
<td>121.14</td>
<td>294.55</td>
</tr>
<tr>
<td>Beverages</td>
<td>270</td>
<td>201.29</td>
<td>520.55</td>
</tr>
<tr>
<td>Dairy</td>
<td>84</td>
<td>50.25</td>
<td>128.32</td>
</tr>
</tbody>
</table>

3. Back on the Basic settings tab of the **tmMondrianInput** component, set the Catalog path to the data warehouse. This catalog describes the structure of the warehouse.
4. Then type in the MDX query such as:

```sql
"select
    { [Measures].[Unit Sales], [Measures].[Store Cost], [Measures].[Store Sales] } on columns,
    CrossJoin(
        { [Promotion Media].[All Media].[Radio],
          [Promotion Media].[All Media].[TV],
          [Promotion Media].[All Media].[Sunday Paper],
          [Promotion Media].[All Media].[Street Handout],
          [Product].[All Products].[Drink].children } on rows
    from Sales
    where ([Time].[1997])"
```

5. Eventually, select the **Encoding** type on the list.

### Job execution

#### Procedure

1. Select the **tLogRow** component and select the **Print header** check box to display the column names on the console.

2. Then press **F6** to run the Job.

```sql
Starting job "Mondrian" at 15:31 08-02-2008

<table>

Job ended at 15:33 08-02-2008. [exit code 0]"

### Results

The console shows the result of the **unit_sales**, **store_cost** and **store_sales** for each type of **Drink** (**Beverages**, **Dairy**, **Alcoholic beverages**) crossed with each media (**TV**, **Sunday Paper**, **Street handout**) as shown previously in a table form.
**tMongoDBBulkLoad**

Imports data files in different formats (CSV, TSV or JSON) into the specified MongoDB database so that the data can be further processed.

**tMongoDBBulkLoad Standard properties**

These properties are used to configure tMongoDBBulkLoad running in the Standard Job framework.

The Standard tMongoDBBulkLoad component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Schema and Edit schema**     | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window. |
| **MongoDB directory**          | Fill in this field with the MongoDB home directory.                                                                                                                                                                                                                                                                                         |
| **Use local DB path**          | Select this check box to provide the information of the local database that you want to use. MongoDB V3.0 and onward versions do not support this feature.  
  - **Local DB path**: type in the path to the local database specified when starting the MongoDB server.                                                                                                                                                                           |
| **Use replica set address**    | Select this check box to define a replica set to be connected.  
  - **Replica set name**: specify the name of the replica set.  
  - **Replica address**: specify multiple MongoDB database servers for failover as needed. Note that if you leave the replica host or replica port unspecified, their default values `localhost` and `27017` will be used.                                                                                   |
| **Server**                     | Hostname or IP address of the database server. Note that the default value `localhost` will be used if the server is not specified.                                                                                                                                                                                                 |
| **Port** | This field is available only when the **Use replica set address** check box is not selected. Listening port of the database server. Note that the default value 27017 will be used if the port is not specified. This field is available only when the **Use replica set address** check box is not selected. |
| **Database** | Type in the name of the database to import data to. |
| **Collection** | Type in the name of the collection to import data to. |
| **Use SSL connection** | Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the `tSetKeystore` component in the same Job to specify the encryption information. Note that the SSL connection is available only for the version 2.4 + of MongoDB. |
| **Drop collection if exist** | Select this check box to remove the collection if it already exists. |
| **Required authentication** | Select this check box to enable the database authentication. Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGOTIATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation. |
| **Set Authentication database** | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed. For further information about the MongoDB Authentication database, see User Authentication database. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. Available when the **Required authentication** check box is selected. If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields. |
| **Data file** | Type in the full path of the file from which the data will be imported or click the [...] button to browse to the desired data file. |
Make sure that the data file is in standard format. For example, the fields in CSV files should be separated with commas.

**File type**
Select the proper file type from the list. CSV, TSV and JSON are supported.

**The JSON file starts with an array**
Select this check box to allow tMongoDBBulkload to read the JSON files starting with an array.
This check box appears when the File type you have selected is JSON.

**Action on data**
Select the action that you want to perform on the data.
- **Insert**: Insert the data into the database.
  Note that when inserting data from CSV or TSV files into the MongoDB database, you need to specify fields either by selecting the First line is header check box or defining them in the schema.
- **Upsert**: Insert the data if they do not exist or update the existing data.
  Note that when upserting data into the MongoDB database, you need to specify a list of fields for the query portion of the upsert operation.

**Upsert fields**
Customize the fields that you want to upsert as needed.
This table is available when you select Upsert from the Action on data list.

**First line is header**
Select this check box to use the first line in CSV or TSV files as a header.
This check box is available only when you select CSV or TSV from the File type list.

**Ignore blanks**
Select this check box to ignore the empty fields in CSV or TSV files.
This check box is available only when you select CSV or TSV from the File type list.

**Print log**
Select this check box to print logs.

**Advanced settings**

**Additional arguments**
Complete this table to use the additional arguments as required.
For example, you can use the argument `--jsonArray` to accept the import of data expressed with multiple MongoDB documents within a single JSON array. For more information about the additional arguments, go to http://docs.mongodb.org/manual/reference/program/mongoimport/ and read the description of options.

**tStatCatcher Statistics**
Select this check box to collect the log data at a component level.
Global Variables

Global Variables

<table>
<thead>
<tr>
<th>Variable Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component can be used together with the tMongoDBInput component to check if the data is imported as expected.

Limitation

The MongoDB client tool needs to be installed on the machine where Jobs using this component are executed.

Importing data into MongoDB database

This scenario applies only to Talend products with Big Data.

The following scenario describes a Job that firstly imports data from a CSV file into the specified MongoDB collection, then reads data from the MongoDB collection to check if the import is successful, next continues to import data from a JSON file with the same data structure into the same MongoDB collection, and finally displays the data from the MongoDB collection to demonstrate that the data from the JSON file is also imported successfully.
Dropping and linking the components

Procedure

1. Drop the following components from the Palette onto the design workspace: two tMongoDBBulkLoad components, two tMongoDBInput components, and two tLogRow components.

2. Connect the first tMongoDBBulkLoad to the first tMongoDBInput using a Trigger > OnSubjobOk link.

3. Connect the first tMongoDBInput to the first tLogRow using a Row > Main link.

4. Repeat the two steps above to connect the second tMongoDBBulkLoad to the second tMongoDBInput, and the second tMongoDBInput to the second tLogRow.

5. Connect the first tMongoDBInput to the second tMongoDBBulkLoad using a Trigger > OnSubjobOk link.

6. Label the two tLogRow components to better identify the data displayed on the console.
Configuring the components

Importing data from a CSV file

Procedure

1. Double-click the first tMongoDBBulkLoad component to open its Basic settings view in the Component tab.

2. In the MongoDB directory field, type in the MongoDB home directory. In this example, it is D:/MongoDB.

3. In the Server and Port fields, fill in the information required for the connection to MongoDB. In this example, type in localhost and 27017.

4. In the Database field, type in the database to import data to, bookstore in this example.

5. In the Collection field, type in the collection to import data to, books in this example.

6. Select the Drop collection if exist check box to remove the specified collection if it already exists.

7. Browse to the desired data file from which you want to import data. In this example, it is D:/Input/books.csv, which is a standard CSV file containing four columns: id, title, author, and category.

8. Select CSV from the File type list.

9. Select Insert from the Action on data list.

10. Select the First line is header check box to use the first line in the CSV file as a header.

11. Select the Ignore blanks check box to ignore the blank fields (if any) in the CSV file.
Validating that the CSV file is imported successfully

Procedure

1. Double-click the first tMongoDBInput component to open its Basic settings view in the Component tab.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, fill in the information required for the connection to MongoDB. In this example, type in localhost and 27017.

4. In the Database field, type in the database from which the data will be read, bookstore in this example.

5. In the Collection field, type in the collection from which the data will be read, books in this example.

6. Click Edit schema to define the data structure to be read from the MongoDB collection.
7. In the Mapping table, the Column field is automatically populated with the defined schema. You do not need to fill in the Parent node path column.

8. Double-click the first tLogRow component to open its Basic settings view in the Component tab.

9. In the Mode area, select Table (print values in cells of a table).

**Importing data from a JSON file**

**Procedure**

1. Double-click the second tMongoDBBulkLoad component to open its Basic settings view in the Component tab.
2. In the **MongoDB directory** field, type in the MongoDB home directory. In this example, it is `D:/MongoDB`.

3. In the **Server** and **Port** fields, fill in the information required for the connection to MongoDB. In this example, type in `localhost` and `27017`.

4. In the **Database** field, type in the target database to import data, `bookstore` in this example.

5. In the **Collection** field, type in the target collection to import data, `books` in this example.

6. Browse to the desired data file from which you want to import data. Here, select `books.json`.

   ```json
   { "id": "4", "title": "Les Miserables", "author": "Victor Hugo", "category": "Language&Literature" } 
   { "id": "5", "title": "Advanced Database Systems", "author": "Carlo Zaniolo", "category": "Database" }
   ```

7. Select **JSON** from the **File type** list.

8. Select **Insert** from the **Action on data** list.

9. Click the **Advanced settings** tab to define the additional arguments as needed.

   ```text
   Additional arguments
   
<table>
<thead>
<tr>
<th>Argument</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>--jsonArray</td>
<td></td>
</tr>
</tbody>
</table>
   ```

   In this example, add the argument `--jsonArray` to accept the imported data within a single JSON array.
Validating that the JSON file is imported successfully

Procedure

1. Repeat Step 1 through Step 7 described in the procedure Validating that the CSV file is imported successfully on page 2276 to configure the second tMongoDBInput component.

2. Repeat Step 8 through Step 9 described in the procedure Validating that the CSV file is imported successfully on page 2276 to configure the second tLogRow component.

Saving and executing the Job

Procedure

1. Press Ctrl + S to save the Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.
The data from the collection *books* in the MongoDB database *bookstore* is displayed on the console, which contains the data imported from both the CSV file *books.csv* and the JSON file *books.json.*
**tMongoDBClose**

Closes a connection to the MongoDB database.

**tMongoDBClose Standard properties**

These properties are used to configure tMongoDBClose running in the Standard Job framework.

The Standard tMongoDBClose component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Component list | Select the tMongoDBConnection component in the list if more than one connection is created for the current Job. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with other MongoDB components, especially tMongoDBConnection. |

**Related scenario**

For a related scenario, see Creating a collection and writing data to it on page 2323.
tMongoDBConnection

Creates a connection to a MongoDB database and reuse that connection in other components.
tMongoDBConnection opens a connection to a database in order that a transaction may be made.

**tMongoDBConnection Standard properties**

These properties are used to configure tMongoDBConnection running in the Standard Job framework.
The Standard tMongoDBConnection component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB Version</strong></td>
<td>List of the database versions.</td>
</tr>
<tr>
<td><strong>Use replica set address</strong></td>

</tr>
</tbody>
</table>
### Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at a component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the <code>cursor.close()</code> method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see [Talend Studio User Guide](https://docs.talend.com/studio/). |

### Usage

| Usage rule | This component is generally used with other MongoDB components, particularly **tMongoClose**. |
Related scenario

For a related scenario, see Creating a collection and writing data to it on page 2323.
**tMongoDBGridFSDelete**

Automates the delete action over specific files in MongoDB GridFS.

`tMongoDBGridFSDelete` connects to a given MongoDB GridFS system, executes a user-defined query to select specific files and deletes these files from this system.

### tMongoDBGridFSDelete Standard properties

These properties are used to configure `tMongoDBGridFSDelete` running in the Standard Job framework.

The Standard `tMongoDBGridFSDelete` component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

#### Basic settings

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
</table>
| **Property type** | Either Built-In or Repository.  
Built-In: No property data stored centrally.  
Repository: Select the repository file where the properties are stored. |
| **Use an existing connection** | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| **Use replica set address or multiple query routers** | Select this check box to show the Server addresses table.  
In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to. |
| **Server and Port** | IP address and listening port of the database server.  
Available when the Use replica set address check box is not selected.  
Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server. |
| **Database** | Name of the database. |
| **Use SSL connection** | Select this check box to enable the SSL or TLS encrypted connection.  
Then you need to use the tSetKeystore component in the same Job to specify the encryption information.  
Note that the SSL connection is available only for the version 2.4 + of MongoDB. |
Set read preference

Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences.

Use authentication

Select this check box to enable the database authentication.

Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

Set Authentication database

If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database.

Username and Password

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

Bucket

Enter the name of the bucket from which you need to delete files. A bucket of GridFS is similar to a folder.

Query type

Select the type of the query you want tMongoDBGridFSDelete to perform to select the files to be deleted.

- **Filename**: you need to enter the name of the file to be deleted. This name is the value of the filename attribute of this file. Note that only one name is allowed.

  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.

- **Mongo Query**: enter the query to be used to select the files to be deleted.

  The example query, `{ }` within double quotation marks provided with tMongoDBGridFSDelete, means to select all of the files in a bucket. You can put
Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>No query timeout</td>
<td>Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the cursor.close() method. A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see <a href="https://docs.mongodb.org/manual/core/cursors/">https://docs.mongodb.org/manual/core/cursors/</a>.</td>
</tr>
</tbody>
</table>

Global Variables

| Global Variables | NB_FILE: the number of files processed. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component combines MongoDB GridFS connection and data iteration, thus usually used as a single-component subjob to delete selected files from a given bucket in MongoDB GridFS. It is often connected to the Job using OnSubjobOk or OnComponentOk link, depending on the context. |

Related scenario

For a scenario using tMongoDBGridFSDelete, see Managing files using MongoDB GridFS on page 2302.
tMongoDBGridFSGet

Connects to a MongoDB GridFS system to copy files from it.
tMongoDBGridFSGet copies files from a given MongoDB GridFS system to a local directory and if needs be, renames these files.

**tMongoDBGridFSGet Standard properties**

These properties are used to configure tMongoDBGridFSGet running in the Standard Job framework.
The Standard tMongoDBGridFSGet component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
BUILT-IN: No property data stored centrally.  
REPOSITORY: Select the repository file where the properties are stored. |
| --- | --- |
| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Use replica set address or multiple query routers | Select this check box to show the Server addresses table.  
In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to. |
| Server and Port | IP address and listening port of the database server.  
Available when the Use replica set address check box is not selected.  
Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server. |
| Database | Name of the database. |
| Use SSL connection | Select this check box to enable the SSL or TLS encrypted connection.  
Then you need to use the tSetKeystore component in the same Job to specify the encryption information.  
Note that the SSL connection is available only for the version 2.4 + of MongoDB. |
| **Set read preference** | Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.  
If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.  
For further information, see MongoDB’s documentation about Replication and its Read preferences. |
|-------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| **Required authentication** | Select this check box to enable the database authentication.  
Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.  
For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation. |
| **Set Authentication database** | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.  
For further information about the MongoDB Authentication database, see User Authentication database. |
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
Available when the Required authentication check box is selected.  
If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields. |
| **Bucket** | Enter the name of the bucket you need to read files from. A bucket of GridFS is similar to a folder. |
| **Query type** | Select the type of the query you want tMongoDBGridFSGet to perform to select the data to be copied.  
- **Filename**: you need to enter the name of the file to be copied. This name is the value of the filename attribute used by this file. Note that only one name is allowed.  
In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.  
- **Mongo Query**: enter the query to be used to select the files to be copied.  
The default query, `{}` within double quotation marks provided with this component, means to select all of the files. You can also apply a regular expression |
by putting 

\{'filename': \{'$regex': 'REGEX_PATTERN'\}'\} to define the file names to be used.

It is recommended to use your query along with the Overwrite local files and the Use Document ID as output filename check boxes to avoid any file name conflict issue.

<table>
<thead>
<tr>
<th>Local Folder</th>
<th>Enter the path to the folder in which the data copied from GridFS is to be written.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Overwrite local files</td>
<td>Select this check box to overwrite the file using the same file name in the local folder being used. Otherwise, an exception will be returned in this type of situation.</td>
</tr>
<tr>
<td>Use Document ID as output filename</td>
<td>Select this box to rename the incoming files on the fly using the values of their object IDs. This allows you keep the files that have the same file names.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
</table>
| No query timeout | Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.  

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use.  

For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/). |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global Variables</strong></td>
<td></td>
</tr>
<tr>
<td><strong>NB_FILE</strong>: the number of files processed. This is an After variable and it returns an integer.</td>
<td></td>
</tr>
</tbody>
</table>
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.  

For further information about variables, see [Talend Studio User Guide](https://docs.talend.com). |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component combines MongoDB GridFS connection and data extraction, thus usually used as a single-compone</th>
</tr>
</thead>
</table>
Related scenario

For a scenario using tMongoDBGridFSGet, see Managing files using MongoDB GridFS on page 2302.
tMongoDBGridFSLit

Retrieves a list of files based on a query.
tMongoDBGridFSLit iterates on files of a bucket in MongoDB GridFS.

**tMongoDBGridFSLit Standard properties**

These properties are used to configure tMongoDBGridFSLit running in the Standard Job framework.
The Standard tMongoDBGridFSLit component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Property type | Either Built-In or Repository.  
|              | **Built-In**: No property data stored centrally.  
|              | **Repository**: Select the repository file where the properties are stored.  
|              | Use an existing connection  
|              | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.  
|              | Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.  
| Use replica set address or multiple query routers | Select this check box to show the Server addresses table.  
|              | In the Server addresses table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to.  
| Server and Port | IP address and listening port of the database server.  
|              | Available when the Use replica set address check box is not selected.  
|              | Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server.  
| Database | Name of the database.  
| Use SSL connection | Select this check box to enable the SSL or TLS encrypted connection.  
|              | Then you need to use the tSetKeystore component in the same Job to specify the encryption information.  
|              | Note that the SSL connection is available only for the version 2.4 + of MongoDB.  

| **Set read preference** | Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences. |
| **Use authentication** | Select this check box to enable the database authentication.

Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation. |
| **Set Authentication database** | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database. |
| **Username and Password** | DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

Available when the Required authentication check box is selected.

If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields. |
| **Bucket** | Enter the name of the bucket in which the files to be listed are stored. A bucket of GridFS is similar to a folder. |
| **Query** | Enter the query to be used to select the files to be listed. You need to define how these files are sorted in the list by selecting:

- **Sort by**: these files can be sorted by their filename attributes, uploadDate attributes or length (the File Size option) attributes.
- **Sort order**: these files can be sorted in the Ascending or Descending order. |
| **Advanced settings** | Select this check box to collect the log data at the component level. |
### No query timeout

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use.

For further information about MongoDB cursors, see https://docs.mongodb.org/manual/core/cursors/.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_FILE: the number of files processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILEID: the value of the ObjectId (the file ID) attribute of the current file. This is an Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILENAME: the value of the filename attribute of the current file. This is an Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILEUPLOADDATE: the value of the uploadDate attribute of the current file. This is an Flow variable and it returns a date.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILELENGTH: the value of the length (the size) attribute of the current file. This is an Flow variable and it returns a length.</td>
</tr>
<tr>
<td></td>
<td>CURRENT_FILEMD5: the value of the md5 attribute of the current file. This is an Flow variable and it returns a string.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component combines MongoDB GridFS connection and data iteration, thus usually used as a single-component subjob to list files stored in a given bucket in MongoDB GridFS. Different lists are returned, each representing an attribute of these files and being stored in a specific global variable as explained above regarding the global variables provided by tMongoDBGridFSList. |

2294
It is often connected to the Job using OnSubjobOk or OnComponentOk link, depending on the context.

Related scenario

For a scenario using tMongoDBGridFSList, see Managing files using MongoDB GridFS on page 2302.
tMongoDBGridFSProperties

Obtains information about the properties of given files selected based on a query.

tMongoDBGridFSProperties iterates on files of a bucket in MongoDB GridFS to extract the attributes of these files.

**tMongoDBGridFSProperties Standard properties**

These properties are used to configure tMongoDBGridFSProperties running in the Standard Job framework.

The Standard tMongoDBGridFSProperties component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>

<thead>
<tr>
<th>Use SSL connection</th>
<th>Select this check box to enable the SSL or TLS encrypted connection.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Then you need to use the tSetKeystore component in the same Job to specify the encryption information.</td>
</tr>
<tr>
<td></td>
<td>Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
</tbody>
</table>
| **Set read preference** | Select this check box and from the **Read preference** drop-down list that is displayed, select the member to which you need to direct the read operations.

If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.

For further information, see MongoDB’s documentation about Replication and its Read preferences. |
| --- | --- |
| **Use authentication** | Select this check box to enable the database authentication. Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGOTIATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation. |
| **Set Authentication database** | If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.

For further information about the MongoDB Authentication database, see User Authentication database. |
| **Username and Password** | DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields. |
| **Bucket** | Enter the name of the bucket in which the files to be used are stored. A bucket of GridFS is similar to a folder. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

The columns of the predefined schema of **tMongoDBGridFS Properties** represent the default attributes of a GridFS file and the column names are already identical with the attribute names.

- If you want to exclude some attributes from the data flow to be processed in your Job, you can remove the columns corresponding to those attributes from this schema. |
• Do not change the names of the columns to be used, because the names of each column must be identical with the name of the file attribute it represents.
• If the files to be processed contain some custom attributes you want to extract, you need to add their representative columns accordingly and ensure that these columns and these custom attributes are using identical names.

**Query type**

Select the type of the query you want to perform to select the files from which you need to extract the attributes.

• **Filename**: you need to enter the name of the file to be used. This name is the value of the `filename` attribute of this file. Note that only one name is allowed.
  In GridFS, a file is identified only by its unique identifier (its object ID); its file name is not necessarily unique.
• **Mongo Query**: enter the query to be used to select the files to be used.
  The example query, `{}` within double quotation marks provided with `tMongoDBGridFSProperties`, means to select all of the files in a bucket. You can put `{'filename':{'$regex':'REGEX_PATTERN'}}` to apply a regular expression to defining the file names to be used.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).

**Global Variables**

**Global Variables**

**NB_FILE**: the number of files processed. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule
This component combines MongoDB GridFS connection and data extraction and needs to use a Main link to connect to its following component in order to send data to this component.

Related scenario

For a scenario using tMongoDBGridFSProperties, see Managing files using MongoDB GridFS on page 2302.
**tMongoDBGridFSPut**

Connects to a MongoDB GridFS system to load files into it.

`tMongoDBGridFSPut` copies files from a local directory, pastes them into a given MongoDB GridFS system and if needs be, renames these files.

**tMongoDBGridFSPut Standard properties**

These properties are used to configure `tMongoDBGridFSPut` running in the Standard Job framework. The Standard `tMongoDBGridFSPut` component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all [Talend products with Big Data](https://www.talend.com/products/big-data) and in [Talend Data Fabric](https://www.talend.com/products/data-fabric).

**Basic settings**

| Property type | Either **Built-In** or **Repository**.  
**Built-In**: No property data stored centrally.  
**Repository**: Select the repository file where the properties are stored. |
|---------------|------------------------------------------------------------------|
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.  
Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level. |
| Use replica set address or multiple query routers | Select this check box to show the **Server addresses** table.  
In the **Server addresses** table, define the sharded MongoDB databases or the MongoDB replica sets you want to connect to. |
| Server and Port | IP address and listening port of the database server.  
Available when the **Use replica set address** check box is not selected.  
Note that if you use the authentication mechanisms to connect to this MongoDB database, you must enter the name, rather than the IP address, of the host of the database server. |
| Database | Name of the database. |
| Use SSL connection | Select this check box to enable the SSL or TLS encrypted connection.  
Then you need to use the **tSetKeystore** component in the same Job to specify the encryption information.  
Note that the SSL connection is available only for the version 2.4 + of MongoDB. |

Managing files using MongoDB GridFS

This scenario applies only to Talend products with Big Data.

In this scenario, the MongoDB GridFS components are used to create a Job to manage video files in MongoDB GridFS.

For further information about the GridFS system of MongoDB, see When to use GridFS.
For demonstration purposes, only one video file, called custom_hadoop.mp4, is used; you can use any of your own video files to replicate this scenario.

**Linking the components**

**Procedure**

1. In the **Integration** perspective of the Studio, create an empty Job, named FS_video for example, from the **Job Designs** node in the **Repository** tree view.
   
   For further information about how to create a Job, see [Talend Studio User Guide](#).

2. In the workspace, enter the name of the component to be used and select this component from the list that appears. In this scenario, the components are `tMongoDBConnection`, `tMongoDBGridFSPut`, `tMongoDBGridFSList`, `tMongoDBGridFSProperties`, `tFilterColumns`, `tLogRow`, `tMongoDBGridFSGet`, and `tMongoDBGridFSDelete`.

3. Connect `tMongoDBConnection` to `tMongoDBGridFSPut` using the **Trigger > On Subjob Ok** link.

4. Repeat this operation to connect `tMongoDBGridFSPut` to `tMongoDBGridFSList`, `tMongoDBGridFSGet`, and then `tMongoDBGridFSGet` to `tMongoDBGridFSDelete`.

5. Connect `tMongoDBGridFSList` to `tMongoDBGridFSProperties` using the **Row > Iterate** link. This link allows `tMongoDBGridFSList` to send data to `tMongoDBGridFSProperties` iteratively.

6. Connect `tMongoDBGridFSProperties` to `tFilterColumns` using the **Row > Main** link.

7. Do the same to connect `tFilterColumns` to `tLogRow`. 
Connecting to MongoDB

Procedure

1. Double-click tMongoDBConnection to open its Component view.

2. From the DB version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the authentication information required for the connection to MongoDB.
   
   If you use the host name of the MongoDB server, ensure that you have added the mapping between this host name and its IP address in the hosts file of the operating system in which the current Job is executed.

4. In the Database field, enter the name of the database hosting GridFS. This database is created on the fly if it does not exist.

Copying data to MongoDB GridFS

Procedure

1. Double-click tMongoDBGridFSPut to open its Component view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket to be used to store files in GridFS. In this example, it is `talend_channel/61`.

4. In the **Local folder** field, enter the path, or browse to the folder where the files to be uploaded to GridFS are stored. As explained previously, it is a video file called `custom_hadoop.mp4`.

5. In the **Files** table, add one row by clicking the `[+]` button and in the **Filemask** column, enter `*.mp4` within the double quotation marks. This allows **tMongoDBGridFSPut** to copy all the files with the `.mp4` extension from the local folder you have specified to the bucket to be used in GridFS.

6. Leave the **New name** column empty, that is to say, leave the double quotation marks in this column as is, so as to keep the name of this video unchanged after being copied to GridFS.

### Listing files stored in MongoDB GridFS

#### Iterating on the files

**Procedure**

1. Double-click **tMongoDBGridFSList** to open its **Component** view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be listed are stored. In this example, it is `talend_channel/61`.

4. In the **Query** field, enter the query to select the files you want `tMongoDBGridFSList` to iterate on to generate different file lists. In this example, leave the default one in order to iterate on all of the files stored in this `talend_channel/61` bucket.

   As explained previously, only one file, `custom_hadoop.mp4`, is expected.

**Extracting file metadata**

**Procedure**

1. Double-click `tMongoDBGridFSProperties` to open its **Component** view.

   ![Component view](image_url)

   2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.
3. In the **Bucket** field, enter the bucket in which the files to be used are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files about which you need to extract the metadata. In this example, select **Filename** to use the `filename` attribute of each GridFS file for query.

5. In the **Filename** field, press **Ctrl + Space** to display the variable list and choose the variable to be used. In this example, select `tMongoDBGridFSList.CURRENT_FILENAME` from the list. Then the expression to use the `CURRENT_FILENAME` variable is automatically added. This allows `tMongoDBGridFSProperties` to read each file name returned by `tMongoDBGridFSList`.

**Filtering attributes**

**Procedure**

1. Double-click `tFilterColumns` to open its **Component** view.

![Component view of tFilterColumns](image)

2. Click the `[...]` button next to **Edit schema** to open the schema editor.

3. On the left side (the input side), select the column to be used and click the button to move this column to the right side (the output side). In this example, move every column to the right side except the `contentType` column.

Each column represents a file attribute and the pre-defined schema of `tMongoDBGridFSProperties` automatically contains these columns.

![Schema of tFilterColumns](image)

4. Click **OK** to validate these changes and accept the propagation prompted by the pop-up dialog box.
**Downloading files from MongoDB GridFS**

**Procedure**

1. Double-click `tMongoDBGridFSGet` to open its **Component** view.

2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be retrieved are stored. In this example, it is `talend_channel/61`.

4. In the **Local folder** field, enter the path to the local folder in which you want to store the downloaded files. In this scenario, it is `C:/tmp/output`.

5. Select the **Use Document ID as output filename** check box to rename each downloaded file using the value of its **ObjectID** attribute.

Since a file in GridFS is distinct by ID rather than by name, it is possible that several files are using the same file name. For this reason, when downloading this kind of files into the same directory without renaming them differently, an exception is returned to alert that the file being downloaded already exists. In order to avoid this error, you can either select the **Overwrite local files** check box to replace the existing one with the latest downloaded file or rename these files on the fly using their IDs. In this example, the strategy of renaming these files is adopted.

**Remove files from MongoDB GridFS**

**Procedure**

1. Double-click `tMongoDBGridFSDelete` to open its **Component** view.
2. Select the **Use existing connection** check box and from the **Connection** list, select the component in which the MongoDB connection to be used is defined.

3. In the **Bucket** field, enter the bucket in which the files to be deleted are stored. In this example, it is `talend_channel/61`.

4. From the **Query type** list, select the approach you want to use to select the files to be deleted. In this example, select **Filename** to use the `filename` attribute of each GridFS file for query.

5. In the **Filename** field, enter the name of the file to be deleted.

### Executing the Job

#### About this task

Then you can run this Job.

The **tLogRow** component is used to present the execution result of the Job.

#### Procedure

1. If you want to configure the presentation mode on its **Component** view, double-click the **tLogRow** component to open the **Component** view and in the **Mode** area, then, select the **Table (print values in cells of a table)** radio box.

2. Press **F6** to run this Job.

#### Results

Once done, the **Run** view is opened automatically, where the metadata of the video `custom_hadoop.mp4` in GridFS is displayed.

```plaintext
Starting Job FS_video at 15:00 06-04-2016,
[statistics] connecting to socket on port 3799
[statistics] connected
<table>
<thead>
<tr>
<th>_id</th>
<th>filename</th>
<th>chunkSize</th>
<th>uploadDate</th>

</tr>
</tbody>
</table>
[statistics] disconnected
Job FS_video ended at 15:01 06-04-2016. [exit code=0]
```
The downloaded file can be found in the directory C:/tmp/output, using its ID as its file name.
tMongoDBInput

Retrieves records from a collection in the MongoDB database and transfers them to the following component for display or storage.
tMongoDBInput retrieves certain documents from a MongoDB database collection by supplying a query document containing the fields the desired documents should match.

tMongoDBInput Standard properties

These properties are used to configure tMongoDBInput running in the Standard Job framework.
The Standard tMongoDBInput component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of the database versions.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>IP address and listening port of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td>Set read preference</td>
<td>Select this check box and from the Read preference drop-down list that is displayed, select the member to which you need to direct the read operations. If you leave this check box clear, the Job uses the default Read preference, that is to say, uses the primary member in a replica set.</td>
</tr>
</tbody>
</table>
Required authentication

Select this check box to enable the database authentication. Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using. For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.

Set Authentication database

If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the Authentication database field that is displayed. For further information about the MongoDB Authentication database, see User Authentication database.

Username and Password

DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. Available when the Required authentication check box is selected. If the security system you have selected from the Authentication mechanism drop-down list is Kerberos, you need to enter the User principal, the Realm and the KDC server fields instead of the Username and the Password fields.

Collection

Name of the collection in the MongoDB database.

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

If a column in the database is a JSON document and you need to read the entire document, put an asterisk (*) in the DB column column, without quotation marks around.
**Query**

Specify the query condition. This field is available only when you have selected **Find query** from the **Query type** drop-down list.

For example, type in `{id:4}` to retrieve the record whose id is 4 from the collection specified in the **Collection** field.

**Note:**
Different from the query statements required in the MongoDB client software, the query here refers to the contents inside `find()`, such as the query here `{id:4}` versus the MongoDB client query `db.blog.find({id:4})`.

**Aggregation stages**

Create a MongoDB aggregation pipeline by adding the stages you want the documents to pass through so as to obtain aggregated results from these documents. This table is available only when you have selected **Aggregation pipeline query** from the **Query type** drop-down list.

Only one stage is allowed per row in this **Aggregation stages** table and the stages are executed one by one in the order you place them in this table.

For example, if you want to aggregate documents about your customers using the `$match` and the `$group` stages, you need to add two rows to this **Aggregation stages** table and define the two stages as follows:

```
"{\$match : {status : 'A'}}"
"{\$group : {\_id : 'cust_id', total : {\$sum : 'amount'}}}"
```

In this aggregation, the customer documents with status A are selected; then among the selected customers, those using the same customer id are grouped and the values from the amount fields of the same customer are summed up.

For a full list of the stages you can use and their related operators, see **Aggregation pipeline operators**.

For further information about MongoDB aggregation pipeline, see **Aggregation pipeline**.

**Mapping**

Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.

For example, in the document reading as follows

```
{ 
    _id: ObjectId("5099803df3f4948bd2f98391"),
    person: { first: "Joe", last: "Walker" }
}
```

The first and the last fields have person as their parent node but the _id field does not have any parent node. So once completed, this **Mapping** table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>
### tMongoDBInput

<table>
<thead>
<tr>
<th><strong>Sort by</strong></th>
<th><strong>last</strong> &quot;person&quot;</th>
</tr>
</thead>
</table>
| Specify the column and choose the order for the sort operation.  
This field is available only when you have selected **Find query** from the **Query type** drop-down list. |

| **Limit** | Type in the maximum number of records to be retrieved.  
This field is available only when you have selected **Find query** from the **Query type** drop-down list. |

### Advanced settings

<table>
<thead>
<tr>
<th><strong>tStatCatcher Statistics</strong></th>
<th>Select this check box to collect the log data at the component level.</th>
</tr>
</thead>
</table>
| **No query timeout**        | Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.  
A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/). |

| **Enable external sort**    | Since the aggregation pipeline stages have a maximum memory use limit (100 megabytes) and a stage exceeding this limit will produce errors, when handling large datasets, select this check box to avoid aggregation stages exceeding this limit.  
For further information about this external sort, see **Large sort operation with external sort**. |

### Global Variables

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |
|----------------------|---------------------------------------------------------------------|
**Usage**

| Usage rule | As a start component, **tMongoDBInput** allows you to retrieve records from a collection in the MongoDB database and transfer them to the following component for display or storage. |

**Retrieving data from a collection by advanced queries**

This scenario applies only to **Talend products with Big Data**.

In this scenario, advanced MongoDB queries are used to retrieve the post by the author Anderson.

There are such posts in the collection **blog** of the MongoDB database **talend**:

```javascript
> db.blog.find()
{ "id" : ObjectId("5226d25e675f26b4a2876888"), "id" : 1, "post" : { "author" : "Andy", "title" : "Open Source Outlook", "keywords" : "Open Source.Talend", "contents" : "Talend, the leader of the open source world..." } }
{ "id" : ObjectId("5226d25e675f26b4a2876889"), "id" : 2, "post" : { "author" : "Andy", "title" : "Data Integration Overview", "keywords" : "Data Integration.Talend", "contents" : "Talend, the leading player in the BI field..." } }
{ "id" : ObjectId("5226d25e675f26b4a287688a"), "id" : 3, "post" : { "author" : "Anderson", "title" : "ELT Overview", "keywords" : "ELT,Talend", "contents" : "Talend, the big name in the ELT circle..." } }
{ "id" : ObjectId("5226d25e675f26b4a287688b"), "id" : 4, "post" : { "author" : "Andy", "title" : "Big Data Bang", "keywords" : "Big Data,Talend", "contents" : "Talend, the driving force for Big Data applications..." } }
```

To insert data into the database, see **Creating a collection and writing data to it** on page 2323.

**Linking the components**

**Procedure**

1. Drop **tMongoDBConnection**, **tMongoDBClose**, **tMongoDBInput** and **tLogRow** onto the workspace.
2. Link **tMongoDBConnection** to **tMongoDBInput** using the **OnSubjobOk** trigger.
3. Link **tMongoDBInput** to **tMongoDBClose** using the **OnSubjobOk** trigger.
4. Link **tMongoDBInput** to **tLogRow** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.
3. In the Server and Port fields, enter the connection details.
4. In the Database field, enter the name of the MongoDB database.
5. Double-click tMongoDBInput to open its Basic settings view.
6. Select the **Use existing connection** option.

7. In the **Collection** field, enter the name of the collection, namely *blog*.

8. Click the ‘[...]’ button next to **Edit schema** to open the schema editor.

9. Click the ‘[+]’ button to add five columns, namely *id, author, title, keywords* and *contents*, with the type as **Integer** and **String** respectively.

10. Click **OK** to close the editor.

11. The columns now appear in the left part of the **Mapping** area.

12. For columns *author, title, keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.
13. In the **Query** box, enter the advanced query statement to retrieve the posts whose author is Anderson:

```
"{post.author : 'Anderson'}"
```

This statement requires that the sub-node of `post`, the node `author`, should have the value “Anderson”.

14. Double-click **tLogRow** to open its **Basic settings** view.

Select **Table (print values in cells of a table)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT, Talend</td>
<td>Talend, the big name in the ELT circle...</td>
</tr>
</tbody>
</table>

As shown above, the post by Anderson is retrieved.

**Related scenarios**

For related scenarios, see:

- Creating a collection and writing data to it on page 2323
- Using MongoDB functions to create a collection and write data to it on page 2339
tMongoDBOutput

Executes the action defined on the collection in the MongoDB database.

tMongoDBOutput inserts, updates, upserts or deletes documents in a MongoDB database collection based on the incoming flow from the preceding component in the Job.

tMongoDBOutput Standard properties

These properties are used to configure tMongoDBOutput running in the Standard Job framework.

The Standard tMongoDBOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of the database versions.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the Replica address table. In the Replica address table, you can define multiple MongoDB database servers for failover. Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>IP address and listening port of the database server. Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection. Then you need to use the tSetKeystore component in the same Job to specify the encryption information. Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td>Set write concern</td>
<td>Select this check box to set the level of acknowledgement requested from for write operations. Then you need to select the level of this operation. For further information, see the related MongoDB documentation on <a href="http://docs.mongodb.org/manual/core/write-concern/">http://docs.mongodb.org/manual/core/write-concern/</a>.</td>
</tr>
</tbody>
</table>
### Bulk write
Select this check box to insert, update or remove data in bulk. Note this feature is available only when the version of MongoDB you are using is 2.6+

Then you need to select **Ordered** or **Unordered** to define how the MongoDB database processes the data sent by the Studio.

- If you select **Ordered**, MongoDB processes the queries sequentially.
- If you select **Unordered**, MongoDB optimizes the bulk write operations without keeping the order in which the individual operations were inserted in the bulk write.

In the **Bulk write size** field, enter the size of each query group to be processed by MongoDB. In the documentation of MongoDB, some restrictions and expected behaviors as to this size are explained. You can find the details on [http://docs.mongodb.org/manual/core/bulk-write-operations/](http://docs.mongodb.org/manual/core/bulk-write-operations/).

### Required authentication
Select this check box to enable the database authentication.

Among the mechanisms listed on the **Authentication mechanism** drop-down list, the **NEGOTIATE** one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.

For details about the other mechanisms in this list, see [MongoDB Authentication](http://docs.mongodb.org) from the MongoDB documentation.

### Set Authentication database
If the username to be used to connect to MongoDB has been created in a specific Authentication database of MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.

For further information about the MongoDB Authentication database, see [User Authentication database](http://docs.mongodb.org).

### Username and Password
DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

Available when the **Required authentication** check box is selected.

If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields.

### Collection
Name of the collection in the MongoDB database.

### Drop collection if exist
Select this check box to drop the collection if it already exists.

### Action on data
The following operations are available:

- **Insert**: insert documents.
- **Set**: modifies the existing fields of an existing document and appends a field if it does not exist in this document.
  
  If you need to apply this action on all the documents in the collection to be used, select the **Update all document** check box that is displayed; otherwise, only the first document is updated.

- **Update**: replaces the existing documents with the incoming data but keeps the technical ID of these documents.

- **Upsert**: inserts a document if it does not exist otherwise it applies the same rules as **Update**.

- **Upsert with set**: inserts a document if it does not exist otherwise it applies the same rules as **Set**.
  
  If you need to apply this action on all the documents in the collection to be used, select the **Update all document** check box that is displayed; otherwise, only the first document is updated.

- **Delete**: delete documents.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.

- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.

- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

### Built-In

You create and store the schema locally for this component only.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Mapping

Each column of the schema defined for this component represents a field of the documents to be read. In this table, you need to specify the parent nodes of these fields, if any.
For example, in the document reading as follows:

```json
{
    _id: ObjectId("5099803df4948bd2f98391"),
    person: { first: "Joe", last: "Walker" }
}
```

The `first` and the `last` fields have `person` as their parent node but the `_id` field does not have any parent node. So once completed, this Mapping table should read as follows:

<table>
<thead>
<tr>
<th>Column</th>
<th>Parent node path</th>
</tr>
</thead>
<tbody>
<tr>
<td>_id</td>
<td></td>
</tr>
<tr>
<td>first</td>
<td>&quot;person&quot;</td>
</tr>
<tr>
<td>last</td>
<td>&quot;person&quot;</td>
</tr>
</tbody>
</table>

Not available when the Generate JSON Document check box is selected in Advanced settings.

**Advanced settings**

**Generate JSON Document**

Select this check box for JSON configuration:

- **Configure JSON Tree**: click the [...] button to open the interface for JSON tree configuration. For more information, see Configuring a JSON Tree on page 3897.
- **Group by**: click the [+] button to add lines and choose the input columns for grouping the records.
- **Remove root node**: select this check box to remove the root node.
- **Data node** and **Query node** (available for update and upsert actions): type in the name of data node and query node configured on the JSON tree.

**Warning:**
These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

**No query timeout**

Select this check box to prevent MongoDB servers from stopping idle cursors at the end of 10-minute inactivity of these cursors. In this situation, an idle cursor will stay open until either the results of this cursor are exhausted or you manually close it using the `cursor.close()` method.

A cursor for MongoDB is a pointer to the result set of a query. By default, that is to say, with this check box being clear, a MongoDB server automatically stops idle cursors after a given inactivity period to avoid excess memory use. For further information about MongoDB cursors, see [https://docs.mongodb.org/manual/core/cursors/](https://docs.mongodb.org/manual/core/cursors/).

**tStatCatcher Statistics**

Select this check box to collect the log data at the component level.
Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tMongoDBOutput executes the action defined on the collection in the MongoDB database based on the flow incoming from the preceding component in the Job. |

Limitation

<table>
<thead>
<tr>
<th>Note:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• The &quot;multi&quot; parameter, which allows to update multiple documents at a time, is not supported. Therefore, if two documents have the same key, the first is always updated, but the second never will.</td>
</tr>
<tr>
<td>• For the update operation, the key cannot be a JSON array.</td>
</tr>
</tbody>
</table>

Creating a collection and writing data to it

This scenario applies only to Talend products with Big Data.

This scenario creates the collection blog and writes post data to it.

Linking the components

Procedure

1. Drop tMongoDBConnection, tFixedFlowInput, tMongoDBOutput, tMongoDBClose, tMongoDBInput and tLogRow onto the workspace.
2. Rename tFixedFlowInput as blog_post_data, tMongoDBOutput as write_data_to_collection, tMongoDBInput as read_data_from_collection and tLogRow as show_data_from_collection.
3. Link tMongoDBConnection to tFixedFlowInput using the OnSubjobOk trigger.
4. Link tFixedFlowInput to tMongoDBOutput using a Row > Main connection.
5. Link tFixedFlowInput to tMongoDBInput using the OnSubjobOk trigger.
7. Link tMongoDBInput to tLogRow using a Row > Main connection.

![Diagram showing data flow from tMongoDBConnection, tLogRow, tMongoDBClose, and tFixedFlowInput components.]

**Configuring the components**

**Procedure**

1. Double-click tMongoDBConnection to open its Basic settings view.

   ![Image of tMongoDBConnection settings view]

   - **Basic settings**
     - **DB Version**: MongoDB 2.1.X
     - **Server**: "localhost" Port 27017
     - **Database**: "talend"

   - **Authentication**: Required authentication

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.

   In the Database field, enter the name of the MongoDB database.

4. Double-click tFixedFlowInput to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

```
1;Andy;Open Source Outlook;Open Source,Talend,Talend, the leader of the open source world...
3;Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...
2;Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
```

5. Double-click **tMongoDBOutput** to open its **Basic settings** view.

Select the **Use existing connection** and **Drop collection if exist** check boxes.

In the **Collection** field, enter the name of the collection, namely **blog**.

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+] button to add five columns in the right part, namely id, author, title, keywords and contents, with the type as Integer and String respectively.

   Click to copy all the columns to the input table.
   Click Ok to close the editor.

8. The columns now appear in the left part of the Mapping area.
   For columns author, title, keywords and contents, enter their parent node post. By doing so, those nodes reside under the node post in the MongoDB collection.

Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

10. Click the [...] button next to **Edit schema** to open the schema editor.

11. Click the [+] button to add five columns, namely *id, author, title, keywords* and *contents*, with the type as **Integer** and **String** respectively.

    Click **OK** to close the editor.

12. The columns now appear in the left part of the **Mapping** area.
For columns *author*, *title*, *keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.

13. In the **Sort by** area, click the [+] button to add one line and enter *id* under **Column**.

Select *asc* from the **Order asc or desc?** column to the right of the *id* column. This way, the retrieved records will appear in ascending order of the *id* column.

### Executing the Job

**Procedure**

1. Press `Ctrl+S` to save the Job.
2. Press `F6` to run the Job.

![MongoDB shell version: 2.2.0](image)

3. Switch to the database *talend* and read data from the collection *blog* in the MongoDB command line client. You can find that *author*, *title*, *keywords* and *contents* all reside under the node *post*. Meanwhile, the records are stored in the same order as the source input.

### Upserting records in a collection

This scenario applies only to [Talend products with Big Data](https://www.talend.com/products/big-data).

This scenario upserts the collection *blog* as an existing record has its author changed and a new record is added. Before the upsert, the collection *blog* looks like:

```
1;Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
2;Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
3;Andy;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...
```

Such records can be inserted to the database following the instructions of [Creating a collection and writing data to it](https://www.talend.com/products/big-data) on page 2323.
**Linking the components**

**Procedure**

1. Drop `tMongoDBConnection`, `tFixedFlowInput`, `tMongoDBOutput`, `tMongoDBClose`, `tMongoDBInput`, and `tLogRow` from the Palette onto the design workspace.

2. Rename `tFixedFlowInput` as `blog_post_data`, `tMongoDBOutput` as `write_data_to_collection`, `tMongoDBInput` as `read_data_from_collection` and `tLogRow` as `show_data_from_collection`.

3. Link `tMongoDBConnection` to `tFixedFlowInput` using the OnSubjobOk trigger.

4. Link `tFixedFlowInput` to `tMongoDBOutput` using a Row > Main connection.

5. Link `tFixedFlowInput` to `tMongoDBInput` using the OnSubjobOk trigger.

7. Link `tMongoDBInput` to `tLogRow` using a Row > Main connection.

**Configuring the components**

**Procedure**

1. Double-click `tMongoDBConnection` to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.

4. In the Database field, enter the name of the MongoDB database.

5. Double-click `tFixedFlowInput` to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data for upserting the MongoDB database, for example:

1;Andy;Open Source Outlook;Open Source,Talend;Talend, the leader of the open source world...
2;Andy;Data Integration Overview;Data Integration,Talend;Talend, the leading player in the DI field...
3;Anderson;ELT Overview;ELT,Talend;Talend, the big name in the ELT circle...
4;Andy;Big Data Bang;Big Data,Talend;Talend, the driving force for Big Data applications...

As shown above, the 3rd record has its author changed and the 4th record is new.

5. Double-click **tMongoDBOutput** to open its **Basic settings** view.

Select the **Use existing connection** and **Die on error** check boxes.

In the **Collection** field, enter the name of the collection, namely **blog**.

Select **Upsert** from the **Action on data** list.

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+] button to add five columns in the right part, namely id, author, title, keywords and contents, with the type as Integer and String respectively.

Click to copy all the columns to the input table.
Click Ok to close the editor.

8. In the Advanced Settings view, select the Generate JSON Document check box.
Select the Remove root node check box.
In the Data node and Query node fields, enter "data" and "query".

9. Click the [...] button next to Configure JSON Tree to open the configuration interface.
10. Right-click the node rootTag and select Add Sub-element from the contextual menu.
In the dialog box that appears, type in data for the Data node:

Click OK to close the window.
Repeat this operation to define query as the Query node.
Right-click the node data and select Set As Loop Element from the contextual menu.

Warning:
These nodes are mandatory for update and upsert actions. They are intended to enable the update and upsert actions though will not be stored in the database.

11. Select all the columns under the Schema list and drop them to the data node.
In the window that appears, select Create as sub-element of target node.
Click OK to close the window.
Repeat this operation to drop the id column from the Schema list under the Query node.

12. Right-click the node id under data and select Add Attribute from the contextual menu.
In the dialog box that appears, type in type as the attribute name:

Click OK to close the window.
Right-click the node @type under id and select Set A Fix Value from the contextual menu.
In the dialog box that appears, type in integer as the attribute value, ensuring the id values are stored as integers in the database.

Click OK to close the window.
Repeat this operation to set this attribute for the id node under Query.
Click OK to close the JSON Tree configuration interface.

Select the **Use existing connection** check box.

In the **Collection** field, enter the name of the collection, namely *blog*.

Click the [...] button next to **Edit schema** to open the schema editor.

Click the [+] button to add five columns, namely *id, author, title, keywords* and *contents*, with the type as *Integer* and *String* respectively.

Click **OK** to close the editor.

The columns now appear in the left part of the **Mapping** area.

For columns *author, title, keywords* and *contents*, enter their parent node *post* so that the data can be retrieved from the correct positions.

14. Double-click **tLogRow** to open its **Basic settings** view.
In the **Mode** area, select **Table (print values in cells of a table)** for better display.

## Executing the Job

### Procedure

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>
<th>Id</th>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source, Talend</td>
<td>Talend, the leader of the open source world...</td>
</tr>
<tr>
<td>2</td>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration, Talend</td>
<td>Talend, the leading player in the BI field...</td>
</tr>
<tr>
<td>3</td>
<td>Anderson</td>
<td>ELT Overview</td>
<td>ELT, Talend</td>
<td>Talend, the big name in the ELT circle...</td>
</tr>
<tr>
<td>4</td>
<td>Andy</td>
<td>Big Data Hugo</td>
<td>Big Data, Talend</td>
<td>Talend, the driving force for Big Data...</td>
</tr>
</tbody>
</table>

As shown above, the 3rd record has its author updated and the 4th record is inserted.
**tMongoDBRow**

Executes the commands and functions of the MongoDB database.

**tMongoDBRow Standard properties**

These properties are used to configure tMongoDBRow running in the Standard Job framework.

The Standard tMongoDBRow component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of the database versions.</td>
</tr>
<tr>
<td></td>
<td>Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Use replica set address</td>
<td>Select this check box to show the Replica address table.</td>
</tr>
<tr>
<td></td>
<td>In the Replica address table, you can define multiple MongoDB database servers for failover.</td>
</tr>
<tr>
<td></td>
<td>Available when the Use existing connection check box is not selected.</td>
</tr>
<tr>
<td>Server and Port</td>
<td>Address and listening port of the database server.</td>
</tr>
<tr>
<td></td>
<td>Available when the Use existing connection or Use replica set address check box is not selected.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Use SSL connection</td>
<td>Select this check box to enable the SSL or TLS encrypted connection.</td>
</tr>
<tr>
<td></td>
<td>Then you need to use the tSetKeystore component in the same Job to specify the encryption information.</td>
</tr>
<tr>
<td></td>
<td>Note that the SSL connection is available only for the version 2.4 + of MongoDB.</td>
</tr>
<tr>
<td>Required authentication</td>
<td>Select this check box to enable the database authentication.</td>
</tr>
<tr>
<td></td>
<td>Among the mechanisms listed on the Authentication mechanism drop-down list, the NEGOTIATE one is recommended if you are not using Kerberos, because it automatically select the authentication mechanism the most adapted to the MongoDB version you are using.</td>
</tr>
<tr>
<td></td>
<td>For details about the other mechanisms in this list, see MongoDB Authentication from the MongoDB documentation.</td>
</tr>
<tr>
<td>Set Authentication database</td>
<td>If the username to be used to connect to MongoDB has been created in a specific Authentication database of</td>
</tr>
</tbody>
</table>
| **tMongoDBRow** | MongoDB, select this check box to enter the name of this Authentication database in the **Authentication database** field that is displayed.  
For further information about the MongoDB Authentication database, see **User Authentication database**. |
|-----------------|------------------------------------------------------------------------------------------------|
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.  
Available when the **Required authentication** check box is selected.  
If the security system you have selected from the **Authentication mechanism** drop-down list is Kerberos, you need to enter the **User principal**, the **Realm** and the **KDC server** fields instead of the **Username** and the **Password** fields. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
| **Execute command** | Select this check box to enter MongoDB commands in the **Command** field for execution.  
- **Command**: in this field, enter the command to be executed, if this command contains one single variable.  
For example, if you need to construct the command  
```
{"isMaster": 1}
```
You need simply enter **isMaster** within quotation marks.  
- **Construct command from keys and values**: if the command to be executed contains multiple variables, select this check box and in the **Command keys and values** table, add the variables and their respective values to be used. |
For example, if you need to construct the following command:

```json
{ renameCollection : "<source_namespace>", to : "<target_namespace>", dropTarget : <true | false> }
```

You need to add three rows to the Command keys and values table and enter one variable-value pair to each row within quotation marks:

<table>
<thead>
<tr>
<th>Key</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>renameCollection</td>
<td>&quot;old_name&quot;</td>
</tr>
<tr>
<td>to</td>
<td>&quot;new_name&quot;</td>
</tr>
<tr>
<td>dropTarget</td>
<td>&quot;false&quot;</td>
</tr>
</tbody>
</table>

- **Construct command from a JSON string**: if you want to directly enter the command to be used, select this check box and enter this command in the JSON string command field that is displayed. Only one command is allowed per `tMongoDBRow`.

For example:

```
{"createIndexes: 'restaurants',
  indexes : [{key : {restaurant_id : 1}, name: 'id_index_2', unique: true}]}"
```

Note that you must use single quotation marks to surround the string values used in the command and double quotation marks to surround the command itself.

For further information about the MongoDB commands you can use in this field, see [https://docs.mongodb.org/manual/reference/command/](https://docs.mongodb.org/manual/reference/command/).

<table>
<thead>
<tr>
<th>Function</th>
<th>Enter MongoDB functions in the Function field for execution. Not available when the Execute command check box is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Parameters value</td>
<td>Click the ![ button to add lines as needed and then define the parameter values in the form of variables or constant values, for example row1.author or 'Andy'. Note that the parameter values correspond to the parameters defined in the Function field, in the same order. Not available when the Execute command check box is selected.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>
Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

Usage

**Usage rule**

**tMongoDBRow** allows you to manipulate the MongoDB database through the MongoDB commands and functions.

Using MongoDB functions to create a collection and write data to it

This scenario applies only to *Talend products with Big Data*.

This scenario creates the collection **blog** and writes post data to it through the MongoDB functions.

**Linking the components**

**Procedure**

1. Drop **tMongoDBConnection**, **tFixedFlowInput**, **tMongoDBRow**, **tMongoDBClose**, **tMongoDBInput** and **tLogRow** onto the workspace.
2. Rename **tFixedFlowInput** as **blog_post_data**, **tMongoDBRow** as **write_data_to_collection**, **tMongoDBInput** as **read_data_from_collection** and **tLogRow** as **show_data_from_collection**.
3. Link **tMongoDBConnection** to **tFixedFlowInput** using the **OnSubjobOk** trigger.
4. Link **tFixedFlowInput** to **tMongoDBRow** using a **Row > Main** connection.
5. Link **tFixedFlowInput** to **tMongoDBInput** using the **OnSubjobOk** trigger.
6. Link **tMongoDBInput** to **tMongoDBClose** using the **OnSubjobOk** trigger.
7. Link **tMongoDBInput** to **tLogRow** using a **Row > Main** connection.
Configuring the components

Procedure

1. Double-click tMongoDBConnection to open its Basic settings view.

2. From the DB Version list, select the MongoDB version you are using.

3. In the Server and Port fields, enter the connection details.
   In the Database field, enter the name of the MongoDB database.

4. Double-click tFixedFlowInput to open its Basic settings view.
Select **Use Inline Content (delimited file)** in the **Mode** area.

In the **Content** field, enter the data to write to the MongoDB database, for example:

Andy;Open Source Outlook;Open Source,Talend,Talend, the leader of the open source world...
Andy;Data Integration Overview;Data Integration,Talend,Talend, the leading player in the DI field...
Andy;ELT Overview;ELT,Talend,Talend, the big name in the ELT circle...

5. Double-click **tMongoDBRow** to open its **Basic settings** view.
Select the **Use existing connection** check box.

In the **Function** field, enter the MongoDB function to create the collection *blog* and insert data to it:

```javascript
"function(author,title,keywords,contents)
{ return db.blog.save(
{author:author,title:title,keywords:keywords,contents:contents}
);
}
"
```

6. Click the [...] button next to **Edit schema** to open the schema editor.
7. Click the [+ ] button to add four columns in the right part, namely author, title, keywords and contents, with the type of String.

Click to copy all the columns to the input table.
Click OK to close the editor.

8. In the Parameters value table, click the [+ ] button to add four lines and enter the values in sequence: row1.author, row1.title, row1.keywords and row1.contents. By doing so, data of row1 will be transferred to the parameters defined in the function.

Select the Use existing connection check box.
In the Collection field, enter the name of the collection, namely blog.

10. Click the [...] button next to Edit schema to open the schema editor.

11. Click the [+ ] button to add four columns, namely author, title, keywords and contents, with the type as String.
Click **OK** to close the editor.

12. Double-click **tLogRow** to open its **Basic settings** view.

![Image of show_data_from_collection(tLogRow_1) dialog box]

In the **Mode** area, select **Table (print values in cells of a table)** for better display.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run the Job.

<table>
<thead>
<tr>
<th>author</th>
<th>title</th>
<th>keywords</th>
<th>contents</th>
</tr>
</thead>
<tbody>
<tr>
<td>Andy</td>
<td>Open Source Outlook</td>
<td>Open Source.Talend</td>
<td>Talend, the leader of the open source world...</td>
</tr>
<tr>
<td>Andy</td>
<td>Data Integration Overview</td>
<td>Data Integration.Talend</td>
<td>Talend, the leading player in the DI field...</td>
</tr>
<tr>
<td>Andy</td>
<td>ETL Overview</td>
<td>ETL.Talend</td>
<td>Talend, the big name in the ETL circle...</td>
</tr>
</tbody>
</table>
tMsgBox

Opens a dialog box with an OK button requiring action from the user.
tMsgBox is a graphical break in the Job execution progress.

**tMsgBox Standard properties**

These properties are used to configure tMsgBox running in the Standard Job framework.
The Standard tMsgBox component belongs to the Misc family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Title</th>
<th>Text entered shows on the title bar of the dialog box created.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Buttons</td>
<td>Listbox of buttons you want to include in the dialog box. The button combinations are restricted and cannot be changed. The <strong>Question</strong> button displays the <strong>Mask Answer</strong> check box. Select this check box if you want to mask the answer you type in the pop-up window that opens when you run the Job.</td>
</tr>
<tr>
<td>Icon</td>
<td>Icon shows on the title bar of the dialog box.</td>
</tr>
<tr>
<td>Message</td>
<td>Free text to display as message on the dialog box. Text can be dynamic (for example: retrieve and show a file name).</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | RESULT: the return value of the component. This is an After variable and it returns a string. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | This component can be used as intermediate step in a data flow or as a start or an end object in the Job flowchart. |
'Hello world!' type test

The following scenario creates a single-component Job, where tMsgBox is used to display the pid (process id) in place of the traditional “Hello World!” message.

Setting up the Job

Procedure
1. Drop a tMsgBox component from the Palette to the design workspace.
2. Define the dialog box display properties:

   - Title: "Talend Open Studio"
   - Buttons: OK
   - Icon: Information
   - Message: "Current date is: " + (Talend Date.getCurrentDate())

'Title' is the message box title, it can be any variable.

3. In the Message field, enter "Current date is: " between double quotation marks. Then click CTRL+Space to display the autocompletion list and select the following system routine, Talend Date.getCurrentDate. Put brackets around this routine.

Executing the Job

Procedure
Switch to the Run tab to execute the Job defined.

Results
The Message box displays the message and requires the user to click OK to go to the next component or end the Job.

After the user clicked OK, the Run log is updated accordingly.
Related topic: see *Talend Studio User Guide*. 
tMSSqlBulkExec

Offers gains in performance while executing the Insert operations to a Microsoft SQL Server database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

**tMSSqlBulkExec Standard properties**

These properties are used to configure tMSSqlBulkExec running in the Standard Job framework.

The Standard tMSSqlBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data is stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>JDBC Provider</td>
<td>Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.</td>
</tr>
<tr>
<td>When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.</td>
<td></td>
</tr>
<tr>
<td>Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

### Remote File Name

Name of the file to be loaded.

**Warning:**

This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Action</strong></th>
<th>Select the action to be carried out. <strong>Bulk insert, Bulk update</strong> and <strong>Bcp query out</strong>, depending on the action selected, the required information varies.</th>
</tr>
</thead>
</table>
| **Additional JDBC parameters** | Specify additional JDBC parameters for the database connection created.  
This property is not available when the **Use an existing connection** check box in the **Basic settings** view is selected. |
| **Fields terminated by** | Character, string or regular expression to separate fields. |
| **Rows terminated** | String (ex: "\n"on Unix) to distinguish rows. |
| **First row** | Type in the number of the row where the action should start. |
| **Code page** | **OEM** code pages used to map a specific set of characters to numerical code point values. |
| **Data file type** | Select the type of data being handled. |
### Output
Select the type for the standard output of the Microsoft SQL Server database:
- to console
- to global variable

This property is available when BCP query out is selected from the Action drop-down list.

### Fire Triggers
Select this check box to execute any insert trigger defined on the table into which data will be loaded during the bulk insert operation.

This property is available when Bulk insert is selected from the Action drop-down list.

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Enable parallel execution
Select this check box to perform high-speed data processing, by treating multiple data flows simultaneously. Note that this feature depends on the database or the application ability to handle multiple inserts in parallel as well as the number of CPU affected. In the Number of parallel executions field, either:
- Enter the number of parallel executions desired.
- Press Ctrl + Space and select the appropriate context variable from the list. For further information, see Talend Studio User Guide.

Note that when parallel execution is enabled, it is not possible to use global variables to retrieve return values in a subjob.
- The Action on table field is not available with the parallelization function. Therefore, you must use a tCreateTable component if you want to create a table.
- When parallel execution is enabled, it is not possible to use global variables to retrieve return values in a subjob.

### Usage
#### Usage rule
This component is to be used along with tMSSqlOutputBulk component. Used together, they can offer gains in performance while feeding a MSSql database.

#### Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic.
Related scenarios

For use cases in relation with **tMSSqlBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
tMSSqlClose

Closes a transaction in the MSSql databases.

**tMSSqlClose Standard properties**

These properties are used to configure tMSSqlClose running in the Standard Job framework.

The Standard tMSSqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

</tr>
</tbody>
</table>
Related scenarios

No scenario is available for the Standard version of this component yet.
**tMSSqlColumnList**

Lists all column names of a given MSSql table.

`tMSSqlColumnList` iterates on all columns of a given table through a defined MS SQL connection.

**tMSSqlColumnList Standard properties**

These properties are used to configure `tMSSqlColumnList` running in the Standard Job framework.

The Standard `tMSSqlColumnList` component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>

</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <code>tMSSqlConnection</code> component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Table name</td>
<td>Enter the name of the table.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | `COLUMN_NAME`: the name of the column currently iterated upon. This is a Flow variable and it returns a string.  
`COLUMN_DEFAULT`: the default value of the column currently iterated upon. This is a Flow variable and it returns a string.  
`IS_NULLABLE`: nullability of the column currently iterated upon. This is a Flow variable and it returns YES if the column allows NULL; otherwise, NO.  
`DATA_TYPE`: the data type of the column currently iterated upon. This is a Flow variable and it returns a string.  
`CHARACTER_MAXIMUM_LENGTH`: the maximum length in number of characters of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.  
`CHARACTER_OCTET_LENGTH`: the maximum length in bytes of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types. |

| **NUMERIC_PRECISION**: the data precision of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types. |
| **NUMERIC_PRECISION_RADIX**: the data precision radix of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types. |
| **NUMERIC_SCALE**: the scale in digits allowed in the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data, exact numeric data, integer data, or monetary data and NULL for other data types. |
| **DATETIME_PRECISION**: the datetime precision in fractional seconds of the column currently iterated upon. This is a Flow variable, and it returns a numeric string if the data type is datetime or smalldatetime; otherwise, it returns NULL. |
| **COLUMN_KEY**: the key indicator of the column currently iterated upon. This is a Flow variable and it returns a string if the column is set to Key; otherwise it returns nothing. |
| **NB_COLUMN**: the number of columns iterated upon so far. This is an After variable and it returns an integer. |
| **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

## Usage

### Usage rule

This component is to be used along with MSSql components, especially with `tMSSqlConnection`.

### Dynamic settings

Click the `[+>` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic...*
Related scenario

For **tMSSqlColumnList** related scenario, see *Iterating on a DB table and listing its column names* on page 2419.
tMSSqlCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

tMSSqlCommit validates the data processed through the job into the connected DB.

**tMSSqlCommit Standard properties**

These properties are used to configure tMSSqlCommit running in the Standard Job framework.

The Standard tMSSqlCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tMSSqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other tMSSql* components, especially with the tMSSqlConnection and tMSSqlRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

## Related scenarios

For a tMSSqlCommit related scenario, see Inserting data in mother/daughter tables on page 2426.
tMSSqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

tMSSqlConnection opens a connection to a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlConnection Standard properties**

These properties are used to configure tMSSqlConnection running in the Standard Job framework.
The Standard tMSSqlConnection component belongs to the Databases and the ELT families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>

</tbody>
</table>
password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, <code>encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;</code> for Azure SQL database connection.</th>
</tr>
</thead>
</table>
| **Use or register a shared DB Connection** | Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.  

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.  

This check box is not available when the **Specify a data source alias** check box is selected. |
| **Specify a data source alias** | Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration.  

This option works only when you deploy and run your Job in **Talend Runtime**.  

This check box is not visible when the **Use or register a shared DB Connection** check box is selected. |
| **Data source alias** | Enter the alias of the data source created on the **Talend Runtime** side.  

This field is available only when the **Specify a data source alias** check box is selected. |
| **Advanced settings** | **Auto Commit**  

Select this check box to commit any changes to the database automatically upon the transaction.  

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.  

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |

2361
Share identity insert in multi table
Select this check box to share `IDENTITY_INSERT` among multiple Microsoft SQL tables that accept data through the same database connection.

This option prevents errors caused by setting `IDENTITY_INSERT` to `ON` (or `OFF`) repeatedly when writing Microsoft SQL tables through a database connection. It is necessary to check this option when the component is used along with multiple `tMSSqlOutput` components with their Turn on Identity insert options checked in the Basic settings tab.

Note that checking this option may decrease the execution performance.

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other `tMSSql*` components, especially with the `tMSSqlCommit` and `tMSSqlRollback` components. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Inserting data into a database table and extracting useful information from it**

The scenario describes a Job that reads the employee data from a text file, inserts the data into a table of an MSSQL database, then extracts useful data from the table, and displays the information on the console.
This scenario involves the following components:

- **tMSSqlConnection**: establishes a connection to the MSSQL server.
- **tFileInputDelimited**: reads the input file, defines the data structure and sends it to the next component.
- **tMSSqlOutput**: writes data it receives from the preceding component into a table of an MSSQL database.
- **tMSSqlInput**: extracts data from the table based on an SQL query.
- **tLogRow**: displays the information it receives from the preceding component on the console.
- **tMSSqlCommit**: commits the transaction in the connected MSSQL server.

### Setting up the Job

**Procedure**

1. Drop the following components from the Palette onto the design workspace: **tMSSqlConnection**, **tFileInputDelimited**, **tMSSqlOutput**, **tMSSqlInput**, **tLogRow**, and **tMSSqlCommit**.
2. Connect **tMSSqlConnection** to **tFileInputDelimited** using a Trigger > OnSubjobOk link.
3. Do the same to connect **tFileInputDelimited** to **tMSSqlInput** and **tMSSqlInput** to **tMSSqlCommit**.
4. Connect **tFileInputDelimited** to **tMSSqlOutput** using a Row > Main link.
5. Do the same to connect **tMSSqlInput** to **tLogRow**.
Configuring the components

Opening a connection to the MSSQL server

Procedure

1. Double-click the `tMSSqlConnection` component to open its Basic settings view in the Component tab.

   ![tMSSqlConnection_1](image)

   - **Host** field: Type in the IP address or hostname of the MSSQL server, `192.168.30.47` in this example.
   - **Port** field: Type in the port number of the database server, `1433` in this example.
   - **Schema** field: Type in the schema name, `dbo` in this example.
   - **Database** field: Type in the database name, `talend` in this example.
   - **Username** and **Password** fields: Enter the credentials for the MSSQL connection.

Reading the input data

Procedure

1. Double-click the `tFileInputDelimited` component to open its Component view.

   ![tFileInputDelimited_1](image)

   - **File name/Stream** field: Click the [...] button next to the File Name/Stream field to browse to the input file. In this example, it is `D:/Input/Employee_Wage.txt`. This text file holds three columns: `id, name` and `wage`.

     ```
     id;name;wage
     51;Harry;2300
     40;Ronald;3796
     17;Theodore;2174
     21;James;19
     ```
3. In the **Header** field, type in 1 to skip the first row of the input file.

4. Click **Edit schema** to define the data to pass on to the **tMSSqlOutput** component. In this example, we define *id* as the key, and specify the length and precision for each column respectively.

Click **OK** to close the schema editor. A dialog box opens, and you can choose to propagate the schema to the next component.

---

**Related topic:** [tFileInputDelimited on page 1015](#)

---

**Writing the data into the database table**

**Procedure**

1. Double-click the **tMSSqlOutput** component to open its **Basic settings** view in the **Component** tab.

2. Type in required information for the connection or use the existing connection you have configured before. In this example, we select the **Use an existing connection** check box. If multiple connections are available, select the connection you want to use from the **Component List** drop-down list.

3. In the **Table** field, type in the name of the table you want to write the data to: **Wage_Info** in this example. You can also click the [...] button next to the **Table** field to open a dialog box and select a proper table.

4. Select **Create table if not exists** from the **Action on table** drop-down list.

5. Select **Insert if not exists** from the **Action on data** drop-down list.

6. Click **Sync columns** to retrieve the schema from the preceding component.
Extracting useful information from the table

Procedure

1. Double-click the **tMSSqlInput** component to open its Basic settings view in the Component tab.

   ![tMSSqlInput](image)

   - **Use an existing connection**
   - **Component List**

   - **Table Name:** Wage_Info
   - **Query Type:** Built-In
   - **Query:**
     ```sql
     SELECT * FROM Wage_Info
     WHERE wage > (SELECT avg(wage) FROM Wage_Info)
     ORDER BY id
     ```

2. Select the **Use an existing connection** check box. If multiple connections are available, select the connection you want to use from the **Component List** drop-down list.

3. Click **Edit schema** to define the data structure to be read from the table. In this example, we need to read all three columns from the table.

   ![Schema of tMSSqlInput](image)

   - **Column**: id, name, wage
   - **Type**: Integer, String, Integer
   - **DB Type**: INT, VARCHAR, INT
   - **N.**: 2, 8, 4
   - **D.**: 1, 1, 1

4. In the **Table Name** field, type in the name of the table you want to read the data from: Wage_Info in this example.

5. In the **Query** field, fill in the SQL query to be executed on the table specified. To obtain the data of employees whose wages are above the average value and order them by id, enter the SQL
query as follows: SELECT * FROM Wage_Info WHERE wage > (SELECT avg(wage) FROM Wage_Info) ORDER BY id

Displaying information on the console

Procedure
1. Double-click the tLogRow component to open its Basic settings view.
2. In the Mode area, select Table (print values in cells of a table).

Committing the transaction and closing the connection

Procedure
1. Double-click the tMSSqlCommit component to open its Basic settings view.
2. Select the Close Connection check box.

Saving and executing the Job

Procedure
1. Press Ctrl+S to save your Job.
2. Execute the Job by pressing F6 or clicking Run on the Run tab.

The information of employees whose wages are above the average value ordered by id is displayed on the console.

<table>
<thead>
<tr>
<th>id</th>

<td>Ulysee</td>
<td>2383</td>
</tr>
<tr>
<td>86</td>
<td>Lyndon</td>
<td>1999</td>
</tr>
</tbody>
</table>
tMSSqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition.

tMSSqlInput reads data and extracts fields based on a query from a Microsoft SQL Server database or a Microsoft Azure SQL database. Then it passes on the field list to the next component via a Main row link.

**tMSSqlInput Standard properties**

These properties are used to configure tMSSqlInput running in the Standard Job framework.

The Standard tMSSqlInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>

<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>JDBC Provider</strong></td>
<td>Select the provider of the JDBC driver to be used, either <strong>Microsoft</strong> (recommended) or <strong>Open source JTDS</strong>.</td>
</tr>
<tr>
<td></td>
<td>When using this component with Datasource in Talend Runtime, you need to use the <strong>Open source JTDS</strong> driver.</td>
</tr>
<tr>
<td></td>
<td>Note that when <strong>Microsoft</strong> is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

| Host | Database server IP address. |
| Port | Listening port number of DB server. |
| Database | Name of the database. |
| Schema | Name of the schema. |
| Username and Password | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
|  | **Built-In:** You create and store the schema locally for this component only. |
|  | **Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
<table>

Usage

Usage rule

This component covers all possible SQL queries for MS SQL server databases.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Related scenarios

For related topics, see:

- tMSSqlConnection on page 2360

For related topic in tContextLoad, see Reading data from different MySQL databases using dynamically loaded connection parameters on page 497.
tMSSqlLastInsertId

Retrieves the last primary keys added by a user to a MSSql table.

tMSSqlLastInsertId displays the last IDs added to a table from a MSSql specified connection.

**tMSSqlLastInsertId Standard properties**

These properties are used to configure tMSSqlLastInsertId running in the Standard Job framework.
The Standard tMSSqlLastInsertId component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>Built-In: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
</tbody>
</table>

**Component list**

Select the tMSSqlConnection component on the Component list to reuse the connection details you already defined, if there are more than one component in this list.
Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer. |
| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
| To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
| For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |

Dynamic settings

| Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
| Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. |
| For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Limitation

| Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
Related scenario

For a related scenario, see Getting the ID for the last inserted record with tMysqlLastInsertId on page 2455
tMSSqlOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tMSSqlOutput writes, updates, makes changes or suppresses entries in a Microsoft SQL Server database or a Microsoft Azure SQL database.

**tMSSqlOutput Standard properties**

These properties are used to configure tMSSqlOutput running in the Standard Job framework.

The Standard tMSSqlOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>![icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>JDBC Provider</strong></th>
<th>Select the provider of the JDBC driver to be used, either <strong>Microsoft</strong> (recommended) or <strong>Open source JTDS</strong>. When using this component with Datasource in Talend Runtime, you need to use the <strong>Open source JTDS</strong> driver. Note that when <strong>Microsoft</strong> is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to <code>mssql-jdbc.jar</code> and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>Default:</strong> No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table:</strong> The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table:</strong> The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists:</strong> The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create:</strong> The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table:</strong> The table content is deleted.</td>
</tr>
<tr>
<td><strong>Turn on identity insert</strong></td>
<td>Select this check box to use your own sequence for the identity value of the inserted records (instead of having the SQL Server pick the next sequential value).</td>
</tr>
<tr>
<td>-----------------------------</td>
<td>--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
</tbody>
</table>
| **Action on data**          | On the data of the table defined, you can perform:  
  **Insert**: Add new entries to the table. If duplicates are found, job stops.  
  **Single Insert Query**: Add entries to the table in a batch  
  **Update**: Make changes to existing entries  
  **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.  
  **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.  
  **Delete**: Remove entries corresponding to the input flow.  
  **Insert if not exist**: Add new entries to the table if they do not exist. |
| **Specify identity field**  | Select this check box to specify the identity field, which is made up of an automatically incrementing identification number. When this check box is selected, three other fields are displayed:  
  **Identity field**: select the column you want to define as the identity field from the list.  
  **Start value**: type in a start value, used for the very first row loaded into the table.  
  **Step**: type in an incremental value, added to the value of the previous row that was loaded. This check box is available only when you select **Drop and create table**, **Create table**, **Create table if not exists**, or **Drop table if exists and create** from the **Action on table** list, and will disappear if you select the **Enable parallel execution** check box in the **Advanced settings** view. If you select this check box with the **Turn on identity insert** check box cleared and the **Create table if not exists** option selected from the **Action on table** list and if the specified table does not exist, only a table will be created without inserting data into it. |

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.*
**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not available when the **Use an existing connection** check box is selected.

**Data source alias**

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

---

**Note:**
You can also specify the identity field from the schema of the component. To do so, set the **DB Type** of the relevant column to **INT IDENTITY**.

**Note:**
When the **Specify identity field** check box is selected, the **INT IDENTITY DB Type** in the schema is ignored.
### Advanced settings

<table>
<thead>
<tr>
<th><strong>Die on error</strong></th>
<th>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</th>
</tr>
</thead>
</table>

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

**Commit every**

Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

**Additional Columns**

This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Type in the name of the schema column to be altered or inserted as new column
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.
- **Position**: Select Before, Replace or After following the action to be performed on the reference column.
- **Reference column**: Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column.

**Use field options**

Select this check box to customize a request, especially when there is double action on data.

**Ignore date validation**

Select this check box to ignore the date validation and insert the data directly into the database for the data types of DATE, DATETIME, DATETIME2 and DATETIMEOFFSET.

**Debug query mode**

Select this check box to display each step during processing entries in a database.

**Support null in "SQL WHERE" statement**

Select this check box if you want to deal with the Null values contained in a DB table.

**Note:**

Make sure that the Nullable check box is selected for the corresponding columns in the schema.
## Use Batch

Select this check box to activate the batch mode for data processing.

This check box is available only when you have selected the **Insert**, the **Update**, the **Single Insert Query** or the **Delete** option in the **Action on data** list.

**Note:**
If you select the **Single Insert Query** option in the **Action on data** list, be aware that the batch size must be lower than or equal to the limit of parameter markers authorized by the JDBC driver (generally 2000) divided by the number of columns. For more information, see **Limitation** below.

## Batch Size

Specify the number of records to be processed in each batch.

This field appears only when the **Use batch mode** check box is selected.

## tStatCatcher Statistics

Select this check box to collect log data at the component level.

## Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. 

2380
## Usage

### Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MSSql database. It also allows you to create a reject flow using a **Row > Rejects** link to filter data in error. For an example of **tMysqlOutput** in use, see [Retrieving data in error with a Reject link](page 2474).

### Dynamic settings

Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](page 2446) and [Reading data from different MySQL databases using dynamically loaded connection parameters](page 497). For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

When the **Single Insert Query** option is selected in the **Action on data** list, an SQL Prepared Statement is generated, for example, `INSERT INTO table (col1, col2, col3) VALUES (?, ?, ?), (?, ?, ?), (?, ?, ?), (?, ?, ?)`. Within brackets are the groups of parameters the number of which cannot exceed 2000, generally, depending on the JDBC driver. Therefore, the batch size should be set so that this limit is respected.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

## Related scenarios

For **tMSSqlOutput** related topics, see:

- **tMSSqlConnection** on page 2360.
- **Inserting a column and altering data using tMysqlOutput** on page 2466.
tMSSqlOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the MSSql database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component, detailed in a separate section. The advantage of using a two step process is that the data can be transformed before it is loaded in the database.

tMSSqlOutputBulk writes a file with columns based on the defined delimiter and the MSSql standards.

**tMSSqlOutputBulk Standard properties**

These properties are used to configure tMSSqlOutputBulk running in the Standard Job framework.

The Standard tMSSqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>

<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning</strong>:</td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows at the end of the records.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
</tr>
</tbody>
</table>

2382
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>

<td>Databases/MS SQL Server</td>
</tr>
</tbody>
</table>

## Related scenarios

For use cases in relation with *tMSSqlOutputBulk*, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
tMSSqlOutputBulkExec

Gains in performance during Insert operations to a Microsoft SQL Server database.

The tMSSqlOutputBulk and tMSSqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tMSSqlOutputBulkExec component.

**tMSSqlOutputBulkExec Standard properties**

These properties are used to configure tMSSqlOutputBulkExec running in the Standard Job framework. The Standard tMSSqlOutputBulkExec component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>

<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored.</td>
</tr>
<tr>
<td></td>
<td>The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

### JDBC Provider
Select the provider of the JDBC driver to be used, either Microsoft (recommended) or Open source JTDS.

When using this component with Datasource in Talend Runtime, you need to use the Open source JTDS driver.

Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

### Host
Database server IP address.
Currently, only localhost, 127.0.0.1 or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using tMSSqlOutputBulkExec is deployed.

### Port
Listening port number of DB server.

### DB name
Name of the database

### Schema
Name of the schema

### Username and Password
DB user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

### Table
Name of the table to be written.
Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

### Action on table
On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
<table>
<thead>
<tr>
<th><strong>Create a table if not exists:</strong></th>
<th>The table is created if it does not exist.</th>

<tr>
<td><strong>Clear a table:</strong></td>
<td>The table content is deleted. You have the possibility to rollback the operation.</td>
</tr>
</tbody>
</table>

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### File Name

Name of the file to be generated and loaded.

**Warning:**

This file is generated on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

### Append

Select this check box to add the new rows at the end of the records.

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true,trustServerCertificate=false;`
### tMSSqlOutputBulkExec

| Field separator | Character, string or regular expression to separate fields. |
| Row separator | String (ex: "\n" on Unix) to distinguish rows. |
| First row | Type in the number of the row where the action should start. |
| Include header | Select this check box to include the column header. |
| Code page | OEM code pages used to map a specific set of characters to numerical code point values. |
| Data file type | Select the type of data being handled. |
| Encoding | Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling. |
| tStatCatcher statistics | Select this check box to collect log data at the component level. |

### Usage

#### Usage rule

This component is mainly used when no particular transformation is required on the data to be loaded onto the database.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the Component List box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

#### Limitation

The database server must be installed on the same machine where the Studio is installed or where the Job using tMSSqlOutputBulkExec is deployed, so that the component functions properly.

### Example

```plaintext
hostNameInCertificate=*.database.windows.net;loginTimeout=t=30; for Azure SQL database connection.
This field is not available if the **Use an existing connection** check box is selected.
```
Related scenarios

For use cases in relation with `tMSSqlOutputBulkExec`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482
- Inserting data in bulk in MySQL database on page 2489
**tMSSqlRollback**

Cancels the transaction commit in the MSSql database and thus avoids to commit part of a transaction involuntarily.

**tMSSqlRollback Standard properties**

These properties are used to configure tMSSqlRollback running in the Standard Job framework.

The Standard tMSSqlRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

| **Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595. |

Related scenario

For **tMSSqlRollback** related scenario, see [Rollback from inserting data in mother/daughter tables](#) on page 2429.
tMSSqlRow

Acts on the actual DB structure or on the data (although without handling data).

tMSSqlRow executes the SQL query stated onto the specified Microsoft SQL Server or Azure SQL database, depending on the nature of the query and the database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tMSSqlRow Standard properties**

These properties are used to configure tMSSqlRow running in the Standard Job framework.

The Standard tMSSqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>

settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For related topics, see:

- Combining two flows for selective output on page 2503
- Procedure on page 622.
- Removing and regenerating a MySQL table index on page 2497.
tMSSqlSCD

Tracks and reflects changes in a dedicated SCD table in a Microsoft SQL Server or Azure SQL database. tMSSqlSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tMSSqlSCD Standard properties**

These properties are used to configure tMSSqlSCD running in the Standard Job framework. The Standard tMSSqlSCD component belongs to the Business Intelligence and the Databases families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

<table>
<thead>
<tr>
<th>JDBC Provider</th>
<th>Select the provider of the JDBC driver to be used, either <strong>Microsoft</strong> (recommended) or <strong>Open source JTDS</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>When using this component with Datasource in Talend Runtime, you need to use the <strong>Open source JTDS</strong> driver.</td>
</tr>
</tbody>
</table>
Note that when Microsoft is selected, you need to download the Microsoft JDBC Driver for SQL Server on Microsoft Download Center, unpack the downloaded zip file, choose a jar in the unzipped folder based on your JRE version, rename the jar to mssql-jdbc.jar and install it manually. For more information about choosing the jar, see the System Requirements information on Microsoft Download Center.

| **Server** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Schema** | Name of the DB schema. |
| **Database** | Name of the database. |
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-in** | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.  
For more information, see SCD management methodology on page 2511. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
### Source keys include Null
Select this check box to allow the source key columns to have Null values.

**Warning:**
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

### Die on error
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Additional JDBC parameters
Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair. For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

### End date time details
Specify the time value of the SCD end date time setting in the format of `HH:mm:ss`. The default value for this field is `12:00:00`.

This field appears only when SCD **Type 2** is used and **Fixed year value** is selected for creating the SCD end date.

### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Debug mode
Select this check box to display each step during processing entries in a database.

### Global Variables

**Global Variables**

**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.

**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.

**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Limitation | This component does not support using SCD type 0 together with other SCD types. |

Related scenario

For related topics, see tMysqlSCD on page 2508.
tMSSqlSP

Offers a convenient way to centralize multiple or complex queries in a database and calls them easily. tMSSqlSP calls the stored procedure in a Microsoft SQL Server or Azure SQL database.

**tMSSqlSP Standard properties**

These properties are used to configure tMSSqlSP running in the Standard Job framework.

The Standard tMSSqlSP component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>

<tr>
<td><strong>Parameters</strong></td>
<td>Click the Plus button and select the various <strong>Schema Columns</strong> that will be required by the procedures. Note</td>
</tr>
</tbody>
</table>
that the SP schema can hold more columns than there are parameters used in the procedure.

Select the **Type** of parameter:

- **IN**: Input parameter
- **OUT**: Output parameter/return value
- **IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).
- **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**
Check Inserting data in mother/daughter tables on page 2426, if you want to analyze a set of records from a database table or DB query and return single records.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

This check box is not available when the **Use an existing connection** check box is selected.

### Data source alias

Enter the alias of the data source created on the **Talend Runtime** side.

This field is available only when the **Specify a data source alias** check box is selected.

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair.

For example, `encrypt=true;trustServerCertificate=false;hostNameInCertificate=*.database.windows.net;loginTimeout=30;` for Azure SQL database connection.

This field is not available if the **Use an existing connection** check box is selected.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Usage

#### Usage rule

This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.

#### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for
example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Limitation

The Stored Procedures syntax should match the Database syntax.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

## Retrieving personal information using a stored procedure

This scenario describes a Job that retrieves a personal information record from a specified table using a stored procedure according to the `id` value defined in the input flow.

In this scenario, the table to retrieve data from contains the personal information. To reproduce this scenario, you can write the data into the table from a CSV file like the following. For how to write data into a MS SQL table, see Inserting data into a database table and extracting useful information from it on page 2362.

```
id;name;sex;age
1;Ford;Male;25
2;Rose;Female;30
3;Sabrina;Female;28
4;Teddy;Male;32
5;Kate;Male;35
```
In this scenario, the stored procedure used to retrieve the personal information is as follows:

```sql
CREATE PROCEDURE [dbo].[QueryPerson]
@id int,
@name varchar(50)
AS
BEGIN
SET NOCOUNT ON
SELECT * FROM dbo.person where id=@id
END
```

**Dropping and linking the components**

**Procedure**

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the Palette: a `tFixedFlowInput` component, a `tMSSqlSP` component, a `tParseRecordSet` component, and two `tLogRow` components.
2. Connect `tFixedFlowInput` to `tMSSqlSP` using a `Row > Main` link.
3. Do the same to connect `tMSSqlSP` to the first `tLogRow`, the first `tLogRow` to `tParseRecordSet`, and `tParseRecordSet` to the second `tLogRow`.

**Configuring the components**

**Configuring the input component**

**Procedure**

1. Double-click `tFixedFlowInput` to open its `Basic settings` view.

2. Click the `[...]` button next to `Edit schema` to open the schema editor.
Click the [+] button to add two columns: *id* of the integer type and *name* of the string type. Click **OK** to close the schema editor.

3. In the **Mode** area, fill each column with respective value. In this example, the *id* value is set to 4, and the *name* value is null since it is not used in the select SQL statement in the stored procedure.

**Configuring the tMSSqlSP component**

**Procedure**

1. Double-click **tMSSqlSP** to open its **Basic settings** view.

2. Fill in the **Host**, **Port**, **Schema**, **Database**, **Username**, and **Password** fields with your MS SQL Server connection details.

3. In the **SP Name** field, enter the name of the stored procedure to be used. In this example, it is *QueryPerson*. 
4. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor](image)

Click the button to copy all columns from the input schema to the output schema, and then click the [+] button in the right panel to add a new column *person* of the object type to hold the personal information to be retrieved from the database.

Click **OK** to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. In the **Parameters** area, click the [+] button to add three rows and select a schema column and its type for each row. In this example, the *id* and *name* columns are of type **IN**, and the *person* column is of type **RECORD SET**.

### Configuring the tParseRecordSet component

**Procedure**

1. Double-click **tParseRecordSet** to open its **Basic settings** view.

![tParseRecordSet](image)

2. From the **Prev. Comp. Column list** drop-down list, select the column that holds the personal information to be parsed. In this example, it is *person*.

3. Click the [...] button next to **Edit schema** to open the schema editor.
Click the [+] button in the right panel to add four columns: id and age of the integer type, and name and sex of the string type.

Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

4. In the Attribute table area, fill in each Value column with the corresponding column name in the MS SQL Server table that holds the personal information.

Configuring the output components

Procedure

1. Double-click the first tLogRow to open its Basic settings view.

In the Mode area, select Vertical (each row is a key/value list) for a better display of the result.

2. Do the same to configure the second tLogRow.

Saving and executing the Job

Procedure

1. Press Ctrl + S to save the Job.

2. Press F6 to run the Job.
The personal information with the id of 4 in the MS SQL table is displayed in the lower table on the console. Note that the values of the id and name columns shown in the upper table are the input data.

### Related scenarios

For related scenarios, see:

- Using tMysqlSP to find a State Label using a stored procedure on page 2528.
- Checking number format using a stored procedure on page 2735.
- Executing a stored procedure using tMDMSP on page 2180.

Check as well Inserting data in mother/daughter tables on page 2426 to analyze a set of records from a database table or DB query and return single records.
tMSSqlTableList

Lists the names of a given set of MSSql tables using a select statement based on a Where clause.

**tMSSqlTableList Standard properties**

These properties are used to configure tMSSqlTableList running in the Standard Job framework.

The Standard tMSSqlTableList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Component list</strong></td>
<td>Select the tMSSqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td><strong>Where clause for table name selection</strong></td>
<td>Enter the Where clause to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **CURRENT_TABLE** | the name of the table currently iterated upon. This is a Flow variable and it returns a string. |
| **NB_TABLE** | the number of tables iterated upon so far. This is a Flow variable and it returns an integer. |
| **ERROR_MESSAGE** | the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with MSSql components, especially with tMSSqlConnection.</th>
</tr>
</thead>
</table>

Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tMSSqlTableList related scenario, see Iterating on a DB table and listing its column names on page 2419.
tMysqlBulkExec

Offers gains in performance while executing the Insert operations on a MySQL or Aurora database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tMysqlBulkExec Standard Properties**

These properties are used to configure tMysqlBulkExec running in the Standard Job framework.

The Standard tMysqlBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the version of the database that you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>
| Action on table | On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| Table | Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed. |
| Local file Name | Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using tMysqlBulkExec is deployed. |
| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

| **Built-In**: You create and store the schema locally for this component only. |
|**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the Basic settings. |
|**Lines terminated by** | Character or sequence of characters used to separate lines. |
|**Fields terminated by** | Character, string or regular expression to separate fields. |
|**Enclosed by** | Character used to enclose text. |
|**Action on data** | On the data of the table defined, you can perform:  
- **Insert records in table**: Add new records to the table.  
- **Update records in table**: Make changes to existing records.  
- **Replace records in table**: Replace existing records with new ones. **Ignore records in table**: Ignore the existing records, or insert the new ones. |
|**Records contain NULL value** | Check this box if you want to retrieve the null values from the input data flow. If you do not check this box, the null values from the input data flow will be considered as empty fields in the output data flow. |
|**Encoding** | Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling. |
### tStatCatcher Statistics
Select this check box to collect log data at the component level.

### Usage

**Usage rule**
This component is to be used along with tMysqlBulkOutput component. Used together, they can offer gains in performance while feeding a MySQL or Aurora database.

**Dynamic settings**
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Related scenarios

For use cases in relation with tMysqlBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
**tMysqlClose**

Closes the transaction committed in a Mysql database.

**tMysqlClose Standard properties**

These properties are used to configure tMysqlClose running in the Standard Job framework.

The Standard tMysqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Mysql components, especially with tMysqlConnection and tMysqlCommit. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenario

This component is closed related to tMysqlConnection and tMysqlRollback. It is often used along with a tMysqlConnection component since it closes an ongoing transaction.

For a scenario related to tMysqlClose, see tMysqlConnection on page 2425.
tMysqlColumnList

Iterates on all columns of a given Mysql table and lists column names.

**tMysqlColumnList Standard properties**

These properties are used to configure tMysqlColumnList running in the Standard Job framework.

The Standard tMysqlColumnList component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Table name</td>
<td>Enter the name of the table.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>COLUMN_NAME: the name of the column currently iterated upon. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>DATA_TYPE: the data type of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_DEFAULT: the default value of the column currently iterated upon. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>IS_NULLABLE: nullability of the column currently iterated upon. This is a Flow variable and it returns YES if the column allows NULL; otherwise, NO.</td>
</tr>
<tr>
<td></td>
<td>COLUMN_KEY: the key indicator of the column currently iterated upon. This is a Flow variable and it returns a string if the column is set to Key; otherwise it returns nothing.</td>
</tr>
<tr>
<td></td>
<td>CHARACTER_MAXIMUM_LENGTH: the maximum length in number of characters of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for binary or character data types and NULL for other types.</td>
</tr>
<tr>
<td></td>
<td>NUMERIC_PRECISION: the data precision of the column currently iterated upon. This is a Flow variable, and it returns a numeric string for approximate numeric data,</td>
</tr>
</tbody>
</table>
### Usage

<table>

</tr>
</tbody>
</table>

### Iterating on a DB table and listing its column names

The following Java scenario creates a five-component job that iterates on a given table name from a Mysql database using a Where clause and lists all column names present in the table.

- Drop the following components from the Palette onto the design workspace: tMysqlConnection, tMysqlTableList, tMysqlColumnList, tFixedFlowInput, and tLogRow.
- Connect tMysqlConnection to tMysqlTableList using an OnSubjobOk link.
• Connect `tMysqlTableList`, `tMysqlColumnList`, and `tFixedFlowInput` using `Iterate` links.
• Connect `tFixedFlowInput` to `tLogRow` using a `Row Main` link.

In the design workspace, select `tMysqlConnection` and click the `Component` tab to define its basic settings.
• In the `Basic settings` view, set the database connection details manually or select them from the context variable list, through a `Ctrl+Space` click in the corresponding field if you have stored them locally as Metadata DB connection entries.

For more information about Metadata, see *Talend Studio User Guide*.

In this example, we want to connect to a Mysql database called `customers`.

• In the design workspace, select `tMysqlTableList` and click the `Component` tab to define its basic settings.

On the `Component list`, select the relevant Mysql connection component if more than one connection is used.
• Enter a Where clause using the right syntax in the corresponding field to iterate on the table name(s) you want to list on the console.
In this scenario, the table we want to iterate on is called `customer`.

- In the design workspace, select `tMysqlColumnList` and click the **Component** tab to define its basic settings.

- On the **Component list**, select the relevant Mysql connection component if more than one connection is used.

- In the **Table name** field, enter the name of the DB table you want to list its column names.

- In the design workspace, select `tFixedFlowInput` and click the **Component** tab to define its basic settings.

- Set the **Schema** to **Built-In** and click the three-dot `[...]` button next to **Edit Schema** to define the data you want to use as input. In this scenario, the schema is made of two columns, the first for the table name and the second for the column name.

- Click **OK** to close the dialog box, and accept propagating the changes when prompted by the system. The defined columns display in the **Values** panel of the **Basic settings** view.

- Click in the **Value** cell for each of the two defined columns and press **Ctrl+Space** to access the global variable list.

- From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))` and `((String)globalMap.get("tMysqlColumnList_1_COLUMN_NAME"))` for the **TableName** and **ColumnName** respectively.
- In the design workspace, select **tLogRow**.
- Click the **Component** tab and define the basic settings for **tLogRow** as needed.
- Save your job and press **F6** to execute it.

```
Starting job Column_Table_List at 00:55 17/11/2008

customer|id
customer|First_Name
customer|Last_Name
customer|Address
customer|id|State
Job Column_Table_List ended at 00:55 17/11/2008. [exit code=0]
```

The name of the DB table is displayed on the console along with all its column names.
tMysqlCommit

Commits in one go, using a unique connection, a global transaction instead of doing that on every row or every batch and thus provides gain in performance.
tMysqlCommit validates the data processed through the Job into the connected DB.

**tMysqlCommit Standard properties**

These properties are used to configure tMysqlCommit running in the Standard Job framework.
The Standard tMysqlCommit component belongs to the Databases family.
The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

---

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

---

**Global Variables**

| Global Variables | **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is more commonly used with other tMysql* components, especially with the tMysqlConnection and tMysqlRollback components.

Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tMysqlCommit related scenario, see Inserting data in mother/daughter tables on page 2426.
**tMysqlConnection**

Opens a connection to the specified MySQL database for reuse in the subsequent subJob or subJobs.

**tMysqlConnection Standard properties**

These properties are used to configure tMysqlConnection running in the Standard Job framework.

The Standard tMysqlConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><em>Built-in:</em> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><em>Repository:</em> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Additional JDBC parameters</td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
<tr>
<td></td>
<td>This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the tRunJob component. Using a shared connection together</td>
</tr>
</tbody>
</table>
with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

This check box is not available when the Specify a data source alias check box is selected.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

**Advanced settings**

**Auto Commit**

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a Job level as well as at each component level.

**Usage**

**Usage rule**

This component is more commonly used with other `tMysql` components, especially with the `tMysqlCommit` and `tMysqlRollback` components.

**Inserting data in mother/daughter tables**

The following Job is dedicated to advanced database users, who want to carry out multiple table insertions using a parent table id to feed a child table.

As a prerequisite to this Job, follow the steps described below to create the relevant tables using an engine such as innodb:

1. In a command line editor, connect to your Mysql server.
2. Once connected to the relevant database, type in the following command to create the parent table:
   ```
   create table f1090_mum(id int not null auto_increment, name varchar(10), primary key(id)) engine=innodb;
   ```
3. Then create the second table:
create table f1090_baby (id_baby int not null, years int) 
engine=innodb;

Back in Talend Studio, the Job requires seven components including tMysqlConnection and tMysqlCommit.

**Linking the components**

**Procedure**

1. Drag and drop the following components from the Palette: a tFileList, a tFileInputDelimited, a tMap, a tMysqlConnection, a tMysqlCommit and two tMysqlOutput.

2. Connect tMysqlConnection to tFileList using an OnComponentOk link.

3. Connect tFileList to tMysqlCommit using an OnComponentOk link.

4. Connect the tFileList component to the input file component using an Iterate link as the name of the file to be processed will be dynamically filled in from the tFileList directory using a global variable.

5. Connect the tFileInputDelimited component to the tMap and dispatch the flow between the two output Mysql DB components. Use a Row link for each for these connections representing the main data flow.

---

**Configuring the components**

**Procedure**

1. Set the tFileList component properties, such as the directory name where files will be fetched from.

2. In the tMysqlConnection Component view, set the connection details manually or fetch them from the Repository if you centrally stored them as a Metadata DB connection entry. For more information about Metadata, see Talend Studio User Guide.

3. On the tFileInputDelimited component’s Basic settings panel, press Ctrl+Space bar to access the variable list. Set the File Name field to the global variable: tFileList_1.CURRENT_FILEPATH.
4. Set the rest of the fields as usual, defining the row and field separators according to your file structure.

5. Then set the schema manually through the **Edit schema** feature or select the schema from the Repository. In Java version, make sure the data type is correctly set, in accordance with the nature of the data processed.

6. In the **tMap** Output area, add two output tables, one called mum for the parent table, the second called baby, for the child table.

   Drag the **Name** column from the **Input** area, and drop it to the mum table.

   Drag the **Years** column from the **Input** area and drop it to the baby table.

7. Make sure the mum table is on the top of the baby table as the order is determining for the flow sequence hence the DB insert to perform correctly.

   Connect the output row link to distribute correctly the flow to the relevant DB output component.

8. In the **Basic settings** tab of the two **tMysqlOutput** components, select the **Use an existing connection** check box to retrieve the **tMysqlConnection** details.

9. Set the **Table** name, making sure it corresponds to the correct table, in this example either **f1090_mum** or **f1090_baby**.
There is no action on the table as they are already created. Select **Insert** as **Action on data** for both output components.

Click on Sync columns to retrieve the schema set in the **tMap**.

10. Switch to the **Advanced settings** tab of the DB output component corresponding to the child table (that is, *f1090_baby*).
   - In the *id-baby* row of the **Additional columns** table, fill the **SQL expression** field with "(Select Last_Insert_id())".
   - Set the **Position** field to **Before**.
   - Set the **Reference column** field to *years*.

These settings allow the *f1090_baby* table to use the ID key of the *f1090_mum* as its key.

11. Clear the **Extend insert** table to use the ID key of the *f1090_mum* as its key.

### Executing the Job

**Procedure**

1. Press **Ctrl + S** to save your Job.
2. Press **F6** to execute it.

```
mysql> select * from f1090_mum
+----+--------+
<table>
<thead>
<tr>
<th>id</th>
<th>names</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>john</td>
</tr>
<tr>
<td>7</td>
<td>bruce</td>
</tr>
<tr>
<td>8</td>
<td>beth</td>
</tr>
<tr>
<td>9</td>
<td>andrew</td>
</tr>
<tr>
<td>10</td>
<td>donald</td>
</tr>
<tr>
<td>11</td>
<td>betty</td>
</tr>
<tr>
<td>12</td>
<td>john</td>
</tr>
<tr>
<td>13</td>
<td>bruce</td>
</tr>
<tr>
<td>14</td>
<td>beth</td>
</tr>
<tr>
<td>15</td>
<td>andrew</td>
</tr>
<tr>
<td>16</td>
<td>donald</td>
</tr>
<tr>
<td>17</td>
<td>betty</td>
</tr>
</tbody>
</table>
+----+--------+
12 rows in set < 0.00 sec

mysql> select * from f1090_baby
+----+-----+----+
<table>
<thead>
<tr>
<th>id_baby</th>
<th>years</th>
<th>id</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td>10</td>
<td>7</td>
</tr>
<tr>
<td>7</td>
<td>23</td>
<td>8</td>
</tr>
<tr>
<td>8</td>
<td>34</td>
<td>9</td>
</tr>
<tr>
<td>9</td>
<td>10</td>
<td>10</td>
</tr>
<tr>
<td>10</td>
<td>23</td>
<td>11</td>
</tr>
<tr>
<td>11</td>
<td>34</td>
<td>12</td>
</tr>
<tr>
<td>12</td>
<td>10</td>
<td>13</td>
</tr>
<tr>
<td>13</td>
<td>23</td>
<td>14</td>
</tr>
<tr>
<td>14</td>
<td>34</td>
<td>15</td>
</tr>
<tr>
<td>15</td>
<td>10</td>
<td>16</td>
</tr>
<tr>
<td>16</td>
<td>23</td>
<td>17</td>
</tr>
<tr>
<td>17</td>
<td>34</td>
<td></td>
</tr>
</tbody>
</table>
+----+-----+----+
12 rows in set < 0.00 sec
```

The parent table *id* has been reused to feed the *id_baby* column.

**Rollback from inserting data in mother/daughter tables**

**About this task**

Based on **Inserting data in mother/daughter tables** on page 2426, insert a rollback function in order to prevent unwanted commit.
**Procedure**

1. Drag and drop `tMysqlRollback` to the design workspace. `tMysqlRollback` ensures that the transaction will not be partly committed.
2. Connect `tFileList` to `tMysqlRollback` with an `OnSubjobError` trigger.
3. Double-click `tMysqlRollback` to enter its `Basic settings` view.
4. From the `Component List`, select the connection component.

**Sharing a database connection between a parent Job and child Job**

This scenario shows how a database connection is shared between a parent Job and a child Job. The parent Job first calls the child Job to write some randomly generated data to a MySQL database, and then reads the data from the MySQL database and displays it on the console. A connection to the MySQL database is set up only once and used in both Jobs.

**Setting up the child Job**

**Adding and linking components**

**Procedure**

1. Add the following components by typing the component names on the design workspace or dropping them from the `Palette`:
   - a `tMysqlConnection` component, to open a connection to the MySQL database,
   - a `tRowGenerator`, to generate random input data,
   - a `tMysqlOutput` component, to write data to the MySQL database.
2. Connect the `tRowGenerator` component to the `tMysqlOutput` component using a `Row > Main` connection.
3. Connect the `tMysqlConnection` component to the `tRowGenerator` using a `Trigger > OnSubjobOk` connection.
Configuring the database connection

Procedure

1. Double-click the **tMysqlConnection** component to open its **Basic settings** view.

2. With the **Property Type** set to **Built-In**, specify the connection details in the relevant fields, including:
   - the host name or IP address of your database server
   - the listening port number
   - the database name
   - the user name and password for your database authentication.

   If you have stored your connection details under the **Metadata** node in the **Repository** tree view, you can simply drop your centralized metadata item onto the **tMysqlConnection** component. For information on how to centralize a database connection, see the chapter on managing metadata of the **Talend Studio User Guide**.

3. Select the **Use or register a shared DB Connection** check box so that the database connection open by this component can be shared across different Jobs. Then, enter a name for the shared connection between double quotes in the **Shared DB Connection Name** field, *shared_mysql_connection* in this example.
Configuring the input data

Procedure

1. Double-click the tRowGenerator component to open the Row Generator editor.

2. Click the [+] button to add four columns and set their properties:
   - **id**, type Integer, 2 characters long.
   - **firstName**, type String, 15 characters long
   - **lastName**, type String, 15 characters long
   - **city**, type String, 15 characters long

3. Define the function for each column:
   - For the **id** column, select **Numeric.sequence** from the Function list to generate sequence numbers.
   - For the **firstName** column, select **TalendDataGenerator.getFirstName** from the Function list to generate random first names.
   - For the **lastName** column, select **TalendDataGenerator.getLastName** from the Function list to generate random family names.
   - For the **city** column, select **TalendDataGenerator.getUsCity** from the Function list to generate random city names.

4. In the **Number of Rows for RowGenerator** field, specify the number of data rows you want to generate, 10 in this example.

5. Click the Preview button on the Preview tab to validate the generator settings.

6. When done, click OK to close the editor and click Yes when prompted to propagate the schema to the next component.
Configuring the database output

Procedure

1. Double-click the tMysqlOutput component to open its Basic settings view.

   ![tMysqlOutput Component Settings](image)

   - **Use an existing connection**
   - **Component List**
   - **Table**: customers
   - **Action on table**: Drop table if exists and create
   - **Action on data**: Insert
   - **Sync columns**

2. Select the **Use an existing connection** check box and, in case you have more than one connection component in the Job, select the connection component to be used from the **Component List** drop-down list.

3. In the **Table** field, enter the name of the database table you are going to write data to, customers in this example.

4. From the **Action on table** list, select the **Drop table if exists and create** option to ensure a clean table is created.

5. From the **Action on data** list, select **Insert**.

6. Click the [...] button next to **Edit schema** to check the output schema. If needed, click **Sync columns** to retrieve the schema from the preceding component.

7. Press **Ctrl+S** to save the Job.

Setting up the parent Job

Arranging data flow for the parent Job

Procedure

1. Add the following components by typing the component names on the design workspace or dropping them from the Palette:
   - a **tRunJob** component, to call the child Job,
   - a **tMysqlConnection** component, to open the MySQL database connection,
   - a **tMysqlInput** component, to read the data written to the MySQL database by the child Job.
   - a **tLogRow** component to display the data on the console,
   - a **tMysqlCommit** component to commit data upon transaction and close the database connection.

2. Connect the **tRunJob** component to the **tMysqlConnection** component using a **Trigger > OnSubjobOk** connection.

3. Connect the **tMysqlConnection** component to the **tMysqlInput** component using a **Trigger > OnSubjobOk** connection.

4. Connect the **tMysqlInput** component to the **tLogRow** component using a **Row > Main** connection.

5. Connect the **tMysqlInput** component to the **tMysqlCommit** component using a **Trigger > OnSubjobOk** connection.
Configuring the components

Procedure

1. Double-click the tRunJob component to open its Basic settings view.
   If a child Job has been already specified in the component, you can open its Basic settings view by right-clicking it and selecting Settings from the contextual menu, or by clicking the component and then selecting the Component tab.

2. Click the [...] button next to the Job field and select the child Job from the Repository Content dialog box. Leave all the other parameters as default.

3. In the Basic settings view of the tMysqlConnection component, select the Use or register a shared DB Connection check box. Then, in the Shared DB Connection Name field, enter the name of the shared connection defined in the child Job, shared_mysql_connection in this example. Leave all the other parameters blank or as default.
4. Double-click the **tMysqlInput** component to open its **Basic settings** view.

5. Select the **Use an existing connection** check box and, in case you have more than one connection component in the Job, select the connection component to be used from the **Component List** drop-down list.

6. Click the [...] button next to **Edit schema** to open the **Schema** editor, and define the same data structure as in the child Job.
When done, click OK to close the dialog and click Yes when prompted to propagate the schema to the next component.

7. Specify the table name in the Table Name list, and click Guess Query to get the query statement automatically filled in the Query field.

8. In the Basic settings view of the tLogRow component, select the Table mode to display the execution result in table cells.

Leave the settings of the tMysqlCommit component unchanged.

Execute the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 or click the Run button on the Run console to execute the Job.

```plaintext

[statistics] disconnected
```

The Job first calls the child Job to write data to the database and then reads the data from the database and displays it on the console.
tMysqlInput

Executes a DB query with a strictly defined order which must correspond to the schema definition.
tMysqlInput reads a database and extracts fields based on a query. Then it passes on the field list to the next component via a Main row link.

**tMysqlInput Standard properties**

These properties are used to configure tMysqlInput running in the Standard Job framework.
The Standard tMysqlInput component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>
| Property type | Either **Built-In** or **Repository**.  
**Built-In**: No property data stored centrally.  
**Repository**: Select the repository file where the properties are stored. |
| ![icon] | Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view.  
For more information about setting up and storing database connection parameters, see Talend Studio User Guide. |
| DB version | Select the version of the database to be used. |
| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>Table Name</td>
<td>Name of the table to be read.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
**Query type and Query**
Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**
Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

**Warning:**
If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

---

**Advanced settings**

**Additional JDBC parameters**
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the **Use an existing connection** check box in the Basic settings.

**Note:** When you need to handle data of the time-stamp type 0000-00-00 00:00:00 using this component, set the parameter as: noDatetimeStringSync=true &zeroDateTimeBehavior=convertToNull.

**Enable stream**
Select this check box to enables streaming over buffering which allows the code to read from a large table without consuming a large amount of memory in order to optimize the performance.

This check box is available only when Mysql 4 or Mysql 5 is selected from the DB Version drop-down list.

**Trim all the String/Char columns**
Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**
Remove leading and trailing whitespace from defined columns.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

---

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for MySQL databases.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the <code>[+]</code> button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

**Writing columns from a MySQL database to an output file using tMysqlInput**

In this scenario we will read certain columns from a MySQL database, and then write them to a table in a local output file.

**Dragging and dropping components and linking them together**

**Procedure**

1. Drop tMysqlInput and tFileOutputDelimited from the Palette onto the workspace.
2. Link tMysqlInput to tFileOutputDelimited using a Row > Main connection.

![Diagram showing connection between tMysqlInput and tFileOutputDelimited](image)

**Configuring the components**

**Procedure**

1. Double-click tMysqlInput to open its Basic Settings view in the Component tab.

   ![Schema editor and property settings](image)

2. From the Property Type list, select Repository if you have already stored the connection to database in the Metadata node of the Repository tree view. The property fields that follow are automatically filled in.

   For more information about how to store a database connection, see Talend Studio User Guide.

   If you have not defined the database connection locally in the Repository, fill in the details manually after selecting Built-in from the Property Type list.

3. Set the Schema as Built-in and click Edit schema to define the desired schema.

   The schema editor opens:
4. Click the [+] button to add the rows that you will use to define the schema, four columns in this example: id, first_name, city and salary.

Under **Column**, click in the fields to enter the corresponding column names.

Click the field under **Type** to define the type of data.

Click **OK** to close the schema editor.

5. Next to the **Table Name** field, click the [...] button to select the database table of interest.

A dialog box displays a tree diagram of all the tables in the selected database:

6. Click the table of interest and then click **OK** to close the dialog box.

7. Set the **Query Type** as **Built-In**.

8. In the **Query** box, enter the query required to retrieve the desired columns from the table.

9. Double-click **tFileOutputDelimited** to set its **Basic settings** in the **Component** tab.
10. Next to the File Name field, click the [...] button to browse your directory to where you want to save the output file, then enter a name for the file. Select the Include Header check box to retrieve the column names as well as the data.

11. Save the Job.

Executing the Job

The results below can be found after F6 is pressed to run the Job.

<table>
<thead>
<tr>
<th></th>
<th>id;first_name;city;salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1;Martin;Sacramento;9011</td>
</tr>
<tr>
<td>2</td>
<td>2;Zachary;Atlanta;8118</td>
</tr>
<tr>
<td>3</td>
<td>3;James;Hartford;5087</td>
</tr>
<tr>
<td>4</td>
<td>4;Herbert;Charleston;9233</td>
</tr>
<tr>
<td>5</td>
<td>5;Herbert;Hartford;5289</td>
</tr>
<tr>
<td>6</td>
<td>6;Ulysses;Nashville;6269</td>
</tr>
</tbody>
</table>

As shown above, the output file is written with the desired column names and corresponding data, retrieved from the database:

Note:
The Job can also be run in the Traces Debug mode, which allows you to view the rows as they are being written to the output file, in the workspace.

Using context parameters when reading a table from a database

In this scenario, MySQL is used for demonstration purposes. We will read a table from a MySQL database, using a context parameter to refer to the table name.

Dragging and dropping components and linking them together

Procedure

1. Drop tMysqlInput and tLogRow from the Palette onto the workspace.
2. Link tMysqlInput to tLogRow using a Row > Main connection.
Configuring the components

Procedure

1. Double-click **tMysqlInput** to open its **Basic Settings** view in the **Component** tab.

2. From the **Property Type** list, select **Repository** if you have already stored the connection to database in the **Metadata** node of the **Repository** tree view. The property fields that follow are automatically filled in.

   For more information about how to store a database connection, see *Talend Studio User Guide*. If you have not defined the database connection in the **Repository**, fill in the details manually after selecting **Built-in** from the **Property Type** list.

3. Set the **Schema** as **Built-In** and click **Edit schema** to define the desired schema.

   The schema editor opens:
4. Click the [+] button to add the rows that you will use to define the schema, seven columns in this example: id, first_name, last_name, city, state, date_of_birth and salary.
   Under Column, click the fields to enter the corresponding column names.
   Click the fields under Type to define the type of data.
   Click OK to close the schema editor.

5. Put the cursor in the Table Name field and press F5 for context parameter setting.

   ![Context Parameter Window]

   For more information about context settings, see Talend Studio User Guide.

6. Keep the default setting in the Name field and type in the name of the database table in the Default value field, employees in this case.

7. Click Finish to validate the setting.

   The context parameter context.TABLE automatically appears in the Table Name field.

8. In the Query type list, select Built-In. Then, click Guess Query to get the query statement.

   In this use case, we want to read the records with the salary above 8000. Therefore, we add a Where clause and the final query statement is as follows:

   ```
   "SELECT '+context.TABLE+'.'id',
   '+context.TABLE+'.'first_name',
   '+context.TABLE+'.'last_name',
   '+context.TABLE+'.'city',
   '+context.TABLE+'.'state',
   '+context.TABLE+'.'date_of_birth',
   '+context.TABLE+'.'salary'
   FROM '+context.TABLE'+
   WHERE '+context.TABLE+'.'salary' > 8000"
   ```

9. Double-click tLogRow to set its Basic Settings in the Component tab.
10. In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.

11. Save the Job.

**Executing the Job**

The results below can be found after **F6** is pressed to run the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
<th>city</th>
<th>state</th>
<th>date_of_birth</th>
<th>salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Martin</td>
<td>Roosevelt</td>
<td>Sacramento</td>
<td>ND</td>
<td>12-10-1950</td>
<td>9011</td>
</tr>
<tr>
<td>2</td>
<td>Zachary</td>
<td>Johnson</td>
<td>Atlanta</td>
<td>ND</td>
<td>14-11-1978</td>
<td>8118</td>
</tr>
<tr>
<td>4</td>
<td>Herbert</td>
<td>Harrison</td>
<td>Charleston</td>
<td>AB</td>
<td>15-08-1963</td>
<td>9233</td>
</tr>
</tbody>
</table>

As shown above, the records with the salary greater than 8000 are retrieved.

**Reading data from databases through context-based dynamic connections**

In this scenario, MySQL is used for demonstration purposes. We will read data from database tables with the same data structure but in two different MySQL databases named *project_q1* and *project_q2* respectively. We will specify the connections to these databases dynamically at runtime, without making any modification to the Job.

**Dropping and linking the components**

**Procedure**

1. Drop two **tMysqlConnection**, a **tMysqlInput**, a **tLogRow**, and a **tMysqlClose** components onto the design workspace.

2. Link the first **tMysqlConnection** to the second **tMysqlConnection** and the second **tMysqlConnection** to **tMysqlInput** using **Trigger > On Subjob Ok** connections.

3. Link **tMysqlInput** to **tLogRow** using a **Row > Main** connection.

4. Link **tMysqlInput** to **tMysqlClose** using a **Trigger > On Subjob Ok** connection.
Creating a context variable

About this task

To be able to choose a database connection dynamically at runtime, we need to define a context variable, which will then be configured in the Dynamic settings of the database input component.

Procedure

1. In the Contexts view, click the [+] button to add a row in the table, click in the Name field and enter a name for the variable, myConnection in this example.

2. From the Type list field, select List Of Value.

3. Click in the Value field and then click the button that appears in the field to open the Configure value of list dialog box.
4. In the **Configure value of list** dialog box, click the **New...** button to open the **New Value** dialog box, and enter the name of one of the connection components in the text field, *tMysqlConnection_1* in this example. Then click **OK** to close the dialog box.

Repeat this step to specify the other connection component name as another list item, *tMysqlConnection_2* in this example.

When done, click **OK** to close the **Configure Values** dialog box.

5. Select the check box next to the variable value field, and fill the **Prompt** field with the message you want to display at runtime, *Select a connection component:* in this example.
Configuring the components

Procedure

1. Double-click the first tMysqlConnection component to show its Basic settings view, and set the connection details. For more information on the configuration of tMysqlConnection, see tMysqlConnection on page 2425. Note that we use this component to open a connection to a MySQL database named project_q1.

![tMysqlConnection_1](image1)

2. Configure the second tMysqlConnection component in the same way, but fill the Database field with project_q2 because we want to use this component to open a connection to another MySQL database, project_q2.

![tMysqlConnection_2](image2)

3. Double-click the tMysqlInput component to show its Basic settings view.

![tMysqlInput_1](image3)

4. Select the Use an existing connection check box, and leave the Component List box as it is.
5. Click the [...] button next to Edit schema to open the Schema dialog box and define the data structure of the database table to read data from.

In this example, the database table structure is made of four columns, `id` (type Integer, 2 characters long), `firstName` (type String, 15 characters long), `lastName` (type String, 15 characters long), and `city` (type String, 15 characters long). When done, click OK to close the dialog box and propagate the schema settings to the next component.

6. Fill the Table field with the database table name, `customers` in this example, and click Guess Query to generate the query statement corresponding to your table schema in the Query field.

7. In the Dynamic settings view, click the [+1] button to add a row in the table, and fill the Code field with the code script of the context variable you just created, " + context.myConnection + " in this example.

8. In the Basic settings view of the tLogRow component, select the Table option for better display effect of the Job execution result.
9. In the **Dynamic settings** view of the **tMysqlClose** component, do exactly the same as in the **Dynamic settings** view of the **tMysqlInput** component.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job and press **F6** or click **Run** to launch it.
   
   A dialog box appears prompting you to specify the connection component you want to use.

2. Select the connection component, **tMysqlConnection_1**, and click **OK**.

The data read from database *project_q1* is displayed in the **Run** console.
3. Press F6 or click Run to launch your Job again. When prompted, select the other connection component, tMysqlConnection_2, to read data from the other database, project_q2. The data read from database project_q2 is displayed in the Run console.

tMysqlLastInsertId

Obtains the primary key value of the record that was last inserted in a Mysql table by a user. tMysqlLastInsertId fetches the last inserted ID from a selected MySQL Connection.

**tMysqlLastInsertId Standard properties**

These properties are used to configure tMysqlLastInsertId running in the Standard Job framework. The Standard tMysqlLastInsertId component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td><strong>Component list</strong></td>
<td>Select the relevant tMysqlConnection component in the list if more than one connection is planned for the current job.</td>
</tr>
</tbody>
</table>
Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | NB_LINE: the number of rows processed. This is an After variable and it returns an integer.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is to be used as an intermediary component. |

Warning:

If you use this component with tMySqlOutput, verify that the Extend Insert check box in the Advanced Settings tab is not selected. Extend Insert allows you to make a batch insertion, however, if the check box is selected, only the ID of the last line in the last batch will be returned.

Dynamic settings

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Getting the ID for the last inserted record with tMysqlLastInsertId

The following Java scenario creates a job that opens a connection to Mysql database, writes the defined data into the database, and finally fetches the last inserted ID on the existing connection.

- Drop the following components from the Palette onto the design workspace: tMySqlConnection, tMySqlCommit, tFileInputDelimited, tMySqlOutput, tMysqlLastInsertId, and tLogRow.
- Connect tMySqlConnection to tFileInputDelimited using an OnSubjobOk link.
- Connect tFileInputDelimited to tMySqlCommit using an OnSubjobOk link.
- Connect tFileInputDelimited to the three other components using Row Main links.

- In the design workspace, select tMysqlConnection.
- Click the Component tab to define the basic settings for tMysqlConnection.
- In the Basic settings view, set the connection details manually or select them from the context variable list, through a Ctrl+Space click in the corresponding field if you stored them locally as Metadata DB connection entries. For more information about Metadata, see Talend Studio User Guide.
• In the design workspace, select **tMysqlCommit** and click the **Component** tab to define its basic settings.
• On the **Component List**, select the relevant **tMysqlConnection** if more than one connection is used.
• In the design workspace, select **tFileInputDelimited**.
• Click the **Component** tab to define the basic settings of **tFileInputDelimited**.

![Image](image1.png)

- Fill in a path to the processed file in the **File Name** field. The file used in this example is *Customers*.
- Define the **Row separator** that allow to identify the end of a row. Then define the **Field separator** used to delimit fields in a row.
- Set the header, the footer and the number of processed rows as necessary. In this scenario, we have one header.
- Click the three-dot button next to **Edit Schema** to define the data to pass on to the next component.

Related topics: *Talend Studio User Guide*.

![Image](image2.png)

In this scenario, the schema consists of two columns, *name* and *age*. The first holds three employees’ names and the second holds the corresponding age for each.

• In the design workspace, select **tMySqlOutput**.
• Click the **Component** tab to define the basic settings of **tMySqlOuptput**.
Select the **Use an existing connection** check box.

In the **Table** field, enter the name of the table where to write the employees’ list, in this example: *employee*.

Select relevant actions on the **Action on table** and **Action on data** lists. In this example, no action is carried out on table, and the action carried out on data is *Insert*.

Click **Sync columns** to synchronize columns with the previous component. In this example, the schema to be inserted into the MySql database table consists of the two columns *name* and *age*.

In the design workspace, select **tMySqlLastInsertId**.

Click the **Component** tab to define the basic settings of **tMySqlLastInsertId**.

On the **Component List**, select the relevant **tMysqlConnection**, if more than one connection is used.

Click **Sync columns** to synchronize columns with the previous component. In the output schema of **tMySqlLastInsertId**, you can see the read-only column *last_insert_id* that will fetch the last inserted ID on the existing connection.
You can select the data type *Long* from the *Type* drop-down list in case of a huge number of entries.

- In the design workspace, select `tLogRow` and click the **Component** tab to define its basic settings. For more information, see `tLogRow` on page 1977.
- Save your job and press **F6** to execute it.

```
Starting job lastinserted at 11:12 01/09/2008.

<table>
<thead>
<tr>
<th>name</th>
<th>age</th>
<th>last_insert_id</th>
</tr>
</thead>
<tbody>
<tr>
<td>Marie</td>
<td>24</td>
<td>40</td>
</tr>
<tr>
<td>Patrick</td>
<td>22</td>
<td>41</td>
</tr>
<tr>
<td>Pierrick</td>
<td>27</td>
<td>42</td>
</tr>
</tbody>
</table>

Job lastinserted ended at 11:12 01/09/2008. [exit code=0]
```

tMysqlLastInsertId fetched the last inserted ID for each line on the existing connection.
tMysqlLookupInput

Reads a MySQL database and extracts fields based on a query.

It passes on the extracted data to tMap in order to provide the lookup data to the main flow. It must be directly connected to a tMap component and requires this tMap to use **Reload at each row** or **Reload at each row (cache)** for the lookup flow.

This component also allows you to connect and read data from a RDS Aurora or a RDS MySQL database.
tMysqlOutput

Writes, updates, makes changes or suppresses entries in a database.

tMysqlOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tMysqlOutput Standard properties**

These properties are used to configure tMysqlOutput running in the Standard Job framework.

The Standard tMysqlOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

| Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595. |

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Property type | Either **Built-In** or **Repository**.  
**Built-In**: No property data stored centrally.  
**Repository**: Select the repository file where the properties are stored. |
| DB Version | Select the MySQL version you are using. |
| ![icon] | Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.  
For more information about setting up and storing database connection parameters, see **Talend Studio User Guide**. |
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
<tr>
<td>Action on table</td>
<td>On the table defined, you can perform one of the following operations: <strong>Default:</strong> No operation is carried out. <strong>Drop and create a table:</strong> The table is removed and created again. <strong>Create a table:</strong> The table does not exist and gets created. <strong>Create a table if not exists:</strong> The table is created if it does not exist. <strong>Drop a table if exists and create:</strong> The table is removed if it already exists and created again. <strong>Clear a table:</strong> The table content is deleted. <strong>Truncate table:</strong> The table content is quickly deleted. However, you will not be able to rollback the operation.</td>
</tr>
<tr>
<td>Action on data</td>
<td>On the data of the table defined, you can perform: <strong>Insert:</strong> Add new entries to the table. If duplicates are found, the job stops. <strong>Update:</strong> Make changes to existing entries. <strong>Insert or update:</strong> Insert a new record. If the record with the given reference already exists, an update would be made. <strong>Update or insert:</strong> Update the record with the given reference. If the record does not exist, a new record would be inserted. <strong>Delete:</strong> Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
**Replace**: Add new entries to the table. If an old row in the table has the same value as a new row for a PRIMARY KEY or a UNIQUE index, the old row is deleted before the new row is inserted.

**Insert or update on duplicate key or unique index**: Add entries if the inserted value does not exist or update entries if the inserted value already exists and there is a risk of violating a unique index or primary key.

**Insert Ignore**: Add only new rows to prevent duplicate key errors.

**Warning**:

You must specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the update and delete operations. To do that: Select the **Use field options** check box and then in the **Key in update** column, select the check boxes next to the column name on which you want to base the update operation. Do the same in the **Key in delete** column for the deletion operation.

---

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

---

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.
| **Die on error** | This check box is selected by default. Clear the check box to skip the row in error and complete the process for error-free rows. If needed, you can retrieve the rows in error via a Row > Rejects link. |
| **Specify a data source alias** | Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. **Warning:** If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified. This check box is not available when the Use an existing connection check box is selected. |

### Advanced settings

| **Use alternate schema** | Select this option to use a schema other than the one specified by the component that establishes the database connection (that is, the component selected from the Component list drop-down list in Basic settings view). After selecting this option, provide the name of the desired schema in the Schema field. This option is available when Use an existing connection is selected in Basic settings view. |
| **Additional JDBC parameters** | Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings. **Note:** You can press Ctrl+Space to access a list of predefined global variables. |
| **Extend Insert** | Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable. **Number of rows per insert:** enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands. **Note:** This option is not compatible with the Reject link. You should therefore clear the check box if you are using a Row > Rejects link with this component. |
Warning:
If you are using this component with `tMysqlLastInsertID`, ensure that the Extend Insert check box in Advanced Settings is not selected. Extend Insert allows for batch loading, however, if the check box is selected, only the ID of the last line of the last batch will be returned.

<table>
<thead>
<tr>
<th>Use Batch</th>
<th>Select this check box to activate the batch mode for data processing.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong></td>
<td>This check box is available only when you have selected, the Update or the Delete option in the Action on data field.</td>
</tr>
</tbody>
</table>

| Batch Size | Specify the number of records to be processed in each batch. This field appears only when the Use batch mode check box is selected. |

| Commit every | Number of rows to be included in the batch before it is committed to the DB. This option ensures transaction quality (but not rollback) and, above all, a higher performance level. |

| Additional Columns | This option is not available if you have just created the DB table (even if you delete it beforehand). This option allows you to call SQL functions to perform actions on columns, provided that these are not insert, update or delete actions, or actions that require pre-processing. |

| Name: | Type in the name of the schema column to be altered or inserted. |
| SQL expression: | Type in the SQL statement to be executed in order to alter or insert the data in the corresponding column. |
| Position: | Select Before, Replace or After, depending on the action to be performed on the reference column. |
| Reference column: | Type in a reference column that `tMySqlOutput` can use to locate or replace the new column, or the column to be modified. |

| Use field options | Select this check box to customize a request, particularly if multiple actions are being carried out on the data. |

| Use Hint Options | Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are: |
| - HINT: | specify the hint you need, using the syntax /**+ */. |
| - POSITION: | specify where you put the hint in a SQL statement. |
| - SQL STMT: | select the SQL statement you need to use. |
### Debug query mode

Select this check box to display each step during processing entries in a database.

### Use duplicate key update mode insert

Updates the values of the columns specified, in the event of duplicate primary keys:

- **Column:** Between double quotation marks, enter the name of the column to be updated.
- **Value:** Enter the action you want to carry out on the column.

**Note:**
To use this option you must first of all select the **Insert** mode in the **Action on data** list found in the **Basic Settings** view.

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement processed. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a MySQL database. It also allows you to create a reject flow using a <strong>Row &gt; Rejects</strong> link to filter data in error. For an example of <strong>tMySqlOutput</strong> in use, see <a href="#">Retrieving data in error with a Reject link</a> on page 2474.</td>
</tr>
</tbody>
</table>
Inserting a column and altering data using tMysqlOutput

This Java scenario is a three-component job that aims at creating random data using a **tRowGenerator**, duplicating a column to be altered using the **tMap** component, and eventually altering the data to be inserted based on an SQL expression using the **tMysqlOutput** component.

- Drop the following components from the **Palette** onto the design workspace: **tRowGenerator**, **tMap** and **tMysqlOutput**.
- Connect **tRowGenerator**, **tMap**, and **tMysqlOutput** using the **Row Main** link.

In the design workspace, select **tRowGenerator** to display its **Basic settings** view.

- Click the **Edit schema** three-dot button to define the data to pass on to the **tMap** component, two columns in this scenario, *name* and *random_date*.
• Click **OK** to close the dialog box.
• Click the **RowGenerator Editor** three-dot button to open the editor and define the data to be generated.

![RowGenerator Editor Image]

• Click in the corresponding **Functions** fields and select a function for each of the two columns, `getFirstName` for the first column and `getRandomDate` for the second column.
• In the **Number of Rows for Rowgenerator** field, enter 10 to generate ten first name rows and click **Ok** to close the editor.
• Double-click the **tMap** component to open the Map editor. The Map editor opens displaying the input metadata of the **tRowGenerator** component.
In the **Schema editor** panel of the Map editor, click the plus button of the output table to add two rows and define the first as `random_date` and the second as `random_date1`.

In this scenario, we want to duplicate the `random_date` column and adapt the schema in order to alter the data in the output component.

- In the **Map editor**, drag the `random_date` row from the input table to the `random_date` and `random_date1` rows in the output table.
Click OK to close the editor.

In the design workspace, double-click the tMysqlOutput component to display its Basic settings view and set its parameters.

Set Property Type to Repository and then click the three-dot button to open the Repository content dialog box and select the correct DB connection. The connection details display automatically in the corresponding fields.

**Note:**
If you have not stored the DB connection details in the Metadata entry in the Repository, select Built-in on the property type list and set the connection detail manually.

Click the three-dot button next to the Table field and select the table to be altered, Dates in this scenario.
• On the **Action on table** list, select **Drop table if exists and create**, select **Insert** on the **Action on data** list.

• If needed, click **Sync columns** to synchronize with the columns coming from the **tMap** component.

• Click the **Advanced settings** tab to display the corresponding view and set the advanced parameters.

In the **Additional Columns** area, set the alteration to be performed on columns.

In this scenario, the **One_month_later** column replaces **random_date_1**. Also, the data itself gets altered using an SQL expression that adds one month to the randomly picked-up date of the **random_date_1** column. ex: 2007-08-12 becomes 2007-09-12.

- Enter **One_Month_Later** in the **Name** cell.

- In the **SQL expression** cell, enter the relevant addition script to be performed, "adddate(Random_date, interval 1 month)" in this scenario.

- Select **Replace** on the **Position** list.

- Enter **Random_date1** on the **Reference column** list.

**Note:**

For this job we duplicated the **random_date_1** column in the DB table before replacing one instance of it with the **One_Month_Later** column. The aim of this workaround was to be able to view upfront the modification performed.

• Save your job and press **F6** to execute it.

The new **One_month_later** column replaces the **random_date1** column in the DB table and adds one month to each of the randomly generated dates.
Updating data using tMysqlOutput

This Java scenario describes a two-component Job that updates data in a MySQL table according to that in a delimited file.

- Drop tFileInputDelimited and tMysqlOutput from the Palette onto the design workspace.
- Connect the two components together using a Row Main link.

- Double-click tFileInputDelimited to display its Basic settings view and define the component properties.
- From the Property Type list, select Repository if you have already stored the metadata of the delimited file in the Metadata node in the Repository tree view. Otherwise, select Built-In to define manually the metadata of the delimited file.

For more information about storing metadata, see Talend Studio User Guide.
In the File Name field, click the three-dot button and browse to the source delimited file that contains the modifications to propagate in the MySQL table.

In this example, we use the customer_update file that holds four columns: id, CustomerName, CustomerAddress and idState. Some of the data in these four columns is different from that in the MySQL table.

Define the row and field separators used in the source file in the corresponding fields.

If needed, set Header, Footer and Limit.

In this example, Header is set to 1 since the first row holds the names of columns, therefore it should be ignored. Also, the number of processed lines is limited to 2000.

Click the three-dot button next to Edit Schema to open a dialog box where you can describe the data structure of the source delimited file that you want to pass to the component that follows.

Select the Key check box(es) next to the column name(s) you want to define as key column(s).

Note:
It is necessary to define at least one column as a key column for the Job to be executed correctly. Otherwise, the Job is automatically interrupted and an error message displays on the console.

In the design workspace, double-click tMysqlOutput to open its Basic settings view where you can define its properties.
Click **Sync columns** to retrieve the schema of the preceding component. If needed, click the three-dot button next to **Edit schema** to open a dialog box where you can check the retrieved schema.

From the **Property Type** list, select **Repository** if you have already stored the connection metadata in the **Metadata** node in the **Repository** tree view. Otherwise, select **Built-In** to define manually the connection information.

For more information about storing metadata, see *Talend Studio User Guide*.

- Fill in the database connection information in the corresponding fields.
- In the **Table** field, enter the name of the table to update.
- From the **Action on table** list, select the operation you want to perform, **Default** in this example since the table already exists.
- From the **Action on data** list, select the operation you want to perform on the data, **Update** in this example.
- Save your Job and press **F6** to execute it.
Using your DB browser, you can verify if the MySQL table, *customers*, has been modified according to the delimited file.

In the above example, the database table has always the four columns *id*, *CustomerName*, *CustomerAddress* and *idState*, but certain fields have been modified according to the data in the delimited file used.

### Retrieving data in error with a Reject link

This scenario describes a four-component Job that carries out migration from a customer file to a MySQL database table and redirects data in error towards a CSV file using a *Reject* link.

![Diagram](image-url)
In the **Repository**, select the customer file metadata that you want to migrate and drop it onto the workspace. In the **Components** dialog box, select **tFileInputDelimited** and click **OK**. The component properties will be filled in automatically.

If you have not stored the information about your customer file under the **Metadata** node in the **Repository**, drop a **tFileInputDelimited** component from the family **File > Input**, in the **Palette**, and fill in its properties manually in the **Component** tab.

From the **Palette**, drop a **tMap** from the **Processing** family onto the workspace.

In the **Repository**, expand the **Metadata** node, followed by the **Db Connections** node and select the connection required to migrate your data to the appropriate database. Drop it onto the workspace. In the **Components** dialog box, select **tMysqlOutput** and click **OK**. The database connection properties will be automatically filled in.

If you have not stored the database connection details under the **Db Connections** node in the **Repository**, drop a **tMysqlOutput** from the **Databases** family in the **Palette** and fill in its properties manually in the **Component** tab.

For more information, see *Talend Studio User Guide*.

From the **Palette**, select a **tFileOutputDelimited** from the **File > Output** family, and drop it onto the workspace.

Link the **customers** component to the **tMap** component, and the **tMap** and **Localhost** with a **Row Main** link. Name this second link **out**.

Link the **Localhost** to the **tFileOutputDelimited** using a **Row > Reject** link.

Double-click the **customers** component to display the **Component** view.

In the **Property Type** list, select **Repository** and click the **[...]** button in order to select the metadata containing the connection to your file. You can also select the **Built-in** mode and fill in the fields manually.

Click the **[...]** button next to the **File Name** field, and fill in the path and the name of the file you want to use.

In the **Row** and **Field Separator** fields, type in between inverted commas the row and field separator used in the file.

In the **Header**, **Footer** and **Limit** fields, type in the number of headers and footers to ignore, and the number of rows to which processing should be limited.

In the **Schema** list, select **Repository** and click the **[...]** button in order to select the schema of your file, if it is stored under the **Metadata** node in the **Repository**. You can also click the **[...]** button next to the **Edit schema** field, and set the schema manually.

The schema is as follows:
• Double-click the **tMap** component to open its editor.

• Select the *id*, *CustomerName*, *CustomerAddress*, *idState*, *id2*, *RegTime* and *RegisterTime* columns on the table on the left and drop them on the **out** table, on the right.
• In the **Schema editor** area, at the bottom of the **tMap** editor, in the right table, change the length of the **CustomerName** column to 28 to create an error. Thus, any data for which the length is greater than 28 will create errors, retrieved with the **Reject** link.

• Click **OK**.

• In the workspace, double-click the output **Localhost** component to display its **Component** view.

• In the **Property Type** list, select **Repository** and click the [...] button to select the connection to the database metadata. The connection details will be automatically filled in. You can also select the **Built-in** mode and set the fields manually.

• In the **Table** field, type in the name of the table to be created. In this scenario, we call it **customers_data**.

• In the **Action on data** list, select the **Create table** option.

• Click the **Sync columns** button to retrieve the schema from the previous component.

• Make sure the **Die on error** check box isn’t selected, so that the Job can be executed despite the error you just created.

• Click the **Advanced settings** tab of the **Component** view to set the advanced parameters of the component.
• Deselect the **Extend Insert** check box which enables you to insert rows in batch, because this option is not compatible with the **Reject** link.

• Double-click the **tFileOutputDelimited** component to set its properties in the **Component** view.

• Click the [...] button next to the **File Name** field to fill in the path and name of the output file.

• Click the **Sync columns** button to retrieve the schema of the previous component.

• Save your Job and press **F6** to execute it.
The data in error are sent to the delimited file, as well as the error type met. Here, we have: **Data truncation.**
tMysqlOutputBulk

Writes a file with columns based on the defined delimiter and the MySQL or Aurora standards.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

tMysqlOutputBulk Standard properties

These properties are used to configure tMysqlOutputBulk running in the Standard Job framework.

The Standard tMysqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated. This file is generated on the same machine where the Studio is installed or where the Job using tMysqlOutputBulk is deployed.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are</td>
<td></td>
</tr>
</tbody>
</table>
not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Advanced settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Text enclosure</strong></td>
<td>Character used to enclose the text.</td>
</tr>
<tr>
<td><strong>Create directory if does not exist</strong></td>
<td>This check box is selected by default. It creates a directory to hold the output table if required.</td>
</tr>
<tr>
<td><strong>Custom the flush buffer size</strong></td>
<td>Customize the amount of memory used to temporarily store output data. In the <strong>Row number field</strong>, enter the number of rows after which the memory is to be freed again.</td>
</tr>
<tr>
<td><strong>Records contain NULL value</strong></td>
<td>This check box is selected by default. It allows you to take account of NULL value fields. If you clear the check box, the NULL values will automatically be replaced with empty values.</td>
</tr>
<tr>
<td><strong>Check disk space</strong></td>
<td>Select the this check box to throw an exception during execution if the disk is full.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect the log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Global Variables</strong></td>
<td><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>

<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the</td>
</tr>
</tbody>
</table>

2481
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with tMySQLBulkExec component. Used together they offer gains in performance while feeding a MySQL or Aurora database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/MySQL</td>
</tr>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Inserting transformed data in MySQL database

This scenario describes a four-component job which aims at fueling a database with data contained in a file, including transformed data. Two steps are required in this job, first step is to create the file, that will then be used in the second step. The first step includes a transformation phase of the data included in the file.
Dropping and linking components

Procedure

1. Drag and drop a tRowGenerator, a tMap, a tMysqlOutputBulk as well as a tMysqlBulkExec component.
2. Connect the main flow using row Main links.
3. And connect the start component (tRowGenerator in this example) to the tMysqlBulkExec using a trigger connection, of type OnComponentOk.

Configuring the components

Procedure

1. A tRowGenerator is used to generate random data. Double-click on the tRowGenerator component to launch the editor.
2. Define the schema of the rows to be generated and the nature of data to generate. In this example, the clients file to be produced will contain the following columns: ID, First Name, Last Name, Address, City which all are defined as string data but the ID that is of integer type.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>N.</th>
<th>Length</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td></td>
<td>int</td>
<td></td>
<td>10</td>
<td>sequence</td>
<td>1</td>
</tr>
<tr>
<td>FirstName</td>
<td></td>
<td>String</td>
<td></td>
<td>2</td>
<td>getFirstName</td>
<td>Jimmy</td>
</tr>
<tr>
<td>LastName</td>
<td></td>
<td>String</td>
<td></td>
<td>14</td>
<td>TalendData</td>
<td>Reagan</td>
</tr>
<tr>
<td>Address</td>
<td></td>
<td>String</td>
<td></td>
<td>14</td>
<td>getUsStreet</td>
<td>Mipas Street</td>
</tr>
<tr>
<td>City</td>
<td></td>
<td>String</td>
<td></td>
<td>14</td>
<td>getUsCity</td>
<td>Juneau</td>
</tr>
</tbody>
</table>

Some schema information don’t necessarily need to be displayed. To hide them away, click on Columns list button next to the toolbar, and uncheck the relevant entries, such as Precision or Parameters.

Use the plus button to add as many columns to your schema definition.

Click the Refresh button to preview the first generated row of your output.

3. Then select the tMap component to set the transformation.
4. Drag and drop all columns from the input table to the output table.
5. Apply the transformation on the *LastName* column by adding `.toUpperCase()` in its expression field. Then, click **OK** to validate the transformation.

6. Double-click on the **tMysqlOutputBulk** component.

7. Define the name of the file to be produced in the **File Name** field. If the delimited file information is stored in the **Repository**, select it in the **Property Type** field, to retrieve relevant data. In this use case the file name is `clients.txt`.

   The schema is propagated from the **tMap** component, if you accepted it when prompted.

8. In this example, don’t include the header information as the table should already contain it.

9. Click **OK** to validate the output.

10. Then double-click on the **tMysqlBulkExec** component to set the INSERT query to be executed.

11. Define the database connection details. We recommend you to store this type of information in the **Repository**, so that you can retrieve them at any time for any Job.

12. Set the table to be filled in with the collected data, in the **Table** field.

13. Fill in the column delimiters in the **Field terminated by** area.

14. Make sure the encoding corresponds to the data encoding.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.
The *clients* database table is filled with data from the file including upper-case *last name* as transformed in the job.

**Results**

For simple Insert operations that don’t include any transformations, the use of `tMysqlOutputBulkExec` allows you to skip a step in the process and thus improves performance.

Related topic: `tMysqlOutputBulkExec Standard properties` on page 2486
tMysqlOutputBulkExec

Executes the Insert action in the specified MySQL or Aurora database.

As a dedicated component, tMysqlBulkExec improves performance when performing Insert operations to a MySQL or Aurora database.

The tMysqlOutputBulk and tMysqlBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT statement used to feed a database. These two steps are fused together in the tMysqlOutputBulkExec component.

**tMysqlOutputBulkExec Standard properties**

These properties are used to configure tMysqlOutputBulkExec running in the Standard Job framework. The Standard tMysqlOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>

<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
<td></td>
</tr>
<tr>
<td><strong>Create table if not exists</strong>: The table is created if it does not already exist.</td>
<td></td>
</tr>
<tr>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
<td></td>
</tr>
<tr>
<td><strong>Clear table</strong>: The table content is deleted.</td>
<td></td>
</tr>
</tbody>
</table>

| **Table** | Name of the table to be written. |
| **Note**: |
| Note that only one table can be written at a time and that the table must already exist for the insert operation to succeed |

| **Local FileName** | Name of the file to be generated and loaded. |
| This file is generated on the same machine where the Studio is installed or where the Job using **tMysqlOutputBulkExec** is deployed. Then it is loaded to the database specified by **Host** field. |

| **Append** | Select the check box for this option to append new rows to the end of the file. |

| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. |
| Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: |
| • **View schema**: choose this option to view the schema only. |
| • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. |
| • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |

| **Built-In**: You create and store the schema locally for this component only. |

| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. |
| You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |

</tbody>
</table>
Inserting data in bulk in MySQL database

This scenario describes a two-component Job which carries out the same operation as the one described for tMysqlOutputBulk Standard properties on page 2480 and tMysqlBulkExec Standard Properties on page 2412, although no data is transformed.

- Drop a tRowGenerator and a tMysqlOutputBulkExec component from the Palette to the design workspace.
- Connect the components using a link such as Row > Main.
- Set the tRowGenerator parameters the same way as in Inserting transformed data in MySQL database on page 2482. The schema is made of four columns including: ID, First Name, Last Name, Address and City.
- In the workspace, double-click the tMysqlOutputBulkExec to display the Component view and set the properties.

- Define the database connection details in the corresponding fields, if necessary. Consult the recommendations detailed in Inserting transformed data in MySQL database on page 2482, concerning the conservation of connection details in the Repository, under the Metadata node. In the component view, select Repository in the Property Type field and then select the appropriate connection in the adjacent field. The following fields will be filled in automatically.

For further information, see Talend Studio User Guide.

- In the Action on table field, select the None option as you want to insert the data into a table which already exists.
- In the Table field, enter the name of the table you want to populate, the name being clients in this example.
- In the Local filename field, indicate the access path and the name of the file which contains the data to be added to the table. In this example, the file is clients.txt.
- Click on the Advanced settings tab to define the component’s advanced parameters.
In the **Action on data** list, select the **Insert records in table** to insert the new data in the table.

- Press **F6** to run the Job.

The result should be pretty much the same as in Inserting transformed data in MySQL database on page 2482, but the data might differ as these are regenerated randomly every time the Job is run.
tMysqlRollback

Cancels the transaction commit in the connected MySQL database to avoid committing part of a transaction involuntarily.

tMysqlRollback Standard properties

These properties are used to configure tMysqlRollback running in the Standard Job framework.
The Standard tMysqlRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tMysql* components, especially with the tMysqlConnection and tMysqlCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection |
parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
tMysqlRow

Executes the stated SQL query on the specified MySQL database.

Depending on the nature of the query and the database, tMysqlRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tMysqlRow is the specific component for MySQL database query. It implements a flow in the Job design although it doesn’t provide output.

**tMysqlRow Standard properties**

These properties are used to configure tMysqlRow running in the Standard Job framework.

The Standard tMysqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the MySQL version that you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](https://help.talend.com).

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>
| **Click Edit schema** | to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema:** choose this option to view the schema only.  
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate |
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Table Name</th>
<th>Name of the table to be processed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Query type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>Fill in manually the query statement or build it graphically using SQLBuilder</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</td>
</tr>
<tr>
<td>Guess Query</td>
<td>Click the Guess Query button to generate the query which corresponds to your table schema in the Query field.</td>
</tr>
<tr>
<td>Query</td>
<td>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row &gt; Rejects link.</td>
</tr>
<tr>
<td>Specify a data source alias</td>
<td>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime. If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified. This check box is not available when the Use an existing connection check box is selected.</td>
</tr>
</tbody>
</table>

Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Propagate QUERY’s recordset</td>
<td>Select this check box to insert the result of the query in a COLUMN of the current flow. Select this column from the use column list. <strong>Note:</strong> This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet.</td>
</tr>
<tr>
<td>Use PreparedStatement</td>
<td>Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement</td>
</tr>
</tbody>
</table>
Parameter table, define the parameters represented by '?' in the SQL instruction of the Query field in the Basic Settings tab.

**Parameter Index**: Enter the parameter position in the SQL instruction.

**Parameter Type**: Enter the parameter type.

**Parameter Value**: Enter the parameter value.

**Note**: This option is very useful if you need to execute the same query several times. Performance levels are increased.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables | QUERY: the query statement being processed. This is a Flow variable and it returns a string. **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component offers the flexibility of the DB query and covers all possible SQL queries. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. |
The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Removing and regenerating a MySQL table index

This scenario describes a four-component job that removes a table index, applies a select insert action onto a table then regenerates the index.

Linking the components

Procedure
1. Select and drop the following components onto the design workspace: tMysqlRow (x2), tRowGenerator, and tMysqlOutput.
2. Link the first tMysqlRow to tRowGenerator using an OnComponentOk connection.
3. Link tRowGenerator to tMysqlOutput using a Row > Main connection.
4. Link tRowGenerator to the second tMysqlRow using an OnSubjobOk connection.

Configuring the components

Procedure
1. Select the tMysqlRow to fill in the DB Basic settings.
2. In Property type as well in Schema, select the relevant DB entry in the list. The DB connection details and the table schema are accordingly filled in.
3. Propagate the properties and schema details onto the other components of the Job.
The query being stored in the Metadata area of the Repository, you can also select Repository in the Query type field and the relevant query entry.

4. If you didn’t store your query in the Repository, type in the following SQL statement to alter the database entries: drop index <index_name> on <table_name>

5. Select the second tMysqlRow component, check the DB properties and schema.

6. Type in the SQL statement to recreate an index on the table using the following statement: create index <index_name> on <table_name> (<column_name>)

The tRowGenerator component is used to generate automatically the columns to be added to the DB output table defined.

7. Select the tMysqlOutput component and fill in the DB connection properties either from the Repository or manually the DB connection details are specific for this use only. The table to be fed is named: comprehensive.

8. The schema should be automatically inherited from the data flow coming from the tLogRow. Edit the schema to check its structure and check that it corresponds to the schema expected on the DB table specified.

The Action on table is None and the Action on data is Insert.

No additional Columns is required for this job.

Executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to run the job.
   
   If you manage to watch the action on DB data, you can notice that the index is dropped at the start of the job and recreated at the end of the insert action.

   Related topics: tDBSQLRow Standard properties on page 619.

Using PreparedStatement objects to query data

This scenario describes a four component job which allows you to link a table column with a client file. The MySQL table contains a list of all the American States along with the State ID, while the file contains the customer information including the ID of the State in which they live. We want to retrieve the name of the State for each client, using an SQL query. In order to process a large volume of data quickly, we use a PreparedStatement object which means that the query is executed only once rather than against each row in turn. Then each row is sent as a parameter. Note that PreparedStatement object can also be used in avoiding SQL injection.

For this scenario, we use a file and a database for which we have already stored the connection and properties in the Repository metadata. For further information concerning the creation of metadata in delimited files, the creation of database connection metadata and the usage of metadata, see Talend Studio User Guide.

Linking the components

Procedure

1. In the Repository, expand the Metadata and File delimited nodes.
2. Select the metadata which corresponds to the client file and slide the metadata onto the workspace. Here, we are using the customers metadata.

3. Double-click tFileInputDelimited in the Components dialog box to add tFileInputDelimited to the workspace, with the relevant fields filled by the metadata file.

4. Drop tMysqlRow, tParseRecordSet and tFileOutputDelimited onto the workspace.

5. Link tFileInputDelimited to tMysqlRow using a Row > Main connection.

6. Link tMysqlRow to tParseRecordSet using a Row > Main connection.

7. Link tParseRecordSet to tFileOutputDelimited using a Row > Main connection.

---

**Configuring the components**

**Procedure**

1. Double-click tFileInputDelimited to open its Basic settings view.

   

2. In the Schema list, select Built-in so that you can modify the component’s schema. Then click on [...] next to the Edit schema field to add a column into which the name of the State will be inserted.
3. Click on the [+ ] button to add a column to the schema. Rename this column LabelStateRecordSet and select Object from the Type list. Click OK to save your modifications.

4. From the Palette, select the tMysqlRow, tParseRecordSet and tFileOutputDelimited components and drop them onto the workspace.

5. Double click tMysqlRow to set its properties in the Basic settings tab of the Component view.
6. In the **Property Type** list, select **Repository** and click on the [...] button to select a database connection from the metadata in the Repository. The **DB Version**, **Host**, **Port**, **Database**, **Username** and **Password** fields are completed automatically. If you are using the **Built-in** mode, complete these fields manually.

7. From the **Schema** list, select **Built-in** to set the schema properties manually and add the **LabelStateRecordSet** column, or click directly on the **Sync columns** button to retrieve the schema from the preceding component.

8. In the **Query** field, enter the SQL query you want to use. Here, we want to retrieve the names of the American States from the **LabelState** column of the MySQL table, **us_state**: "SELECT LabelState FROM us_state WHERE idState=?". The question mark, "?", represents the parameter to be set in the **Advanced settings** tab.

9. Click **Advanced settings** to set the components advanced properties.

10. Select the **Propagate QUERY's recordset** check box and select the **LabelStateRecordSet** column from the **use column** list to insert the query results in that column.

11. Select the **Use PreparedStatement** check box and define the parameter used in the query in the **Set PreparedStatement Parameters** table.

12. Click on the [+] button to add a parameter.

   a) In the **Parameter Index** cell, enter the parameter position in the SQL instruction. Enter "1" as we are only using one parameter in this example.

   b) In the **Parameter Type** cell, enter the type of parameter. Here, the parameter is a whole number, hence, select **Int** from the list.

   c) In the **Parameter Value** cell, enter the parameter value. Here, we want to retrieve the name of the State based on the State ID for every client in the input file. Hence, enter "row1.idState".

13. Double click **tParseRecordSet** to set its properties in the **Basic settings** tab of the **Component** view.
a) From the **Prev. Comp. Column list**, select the preceding components column for analysis. In this example, select `LabelStateRecordSet`.

b) Click on the **Sync columns** button to retrieve the schema from the preceding component. The **Attribute table** is automatically completed with the schema columns.

c) In the **Attribute table**, in the **Value** field which corresponds to the `LabelStateRecordSet`, enter the name of the column containing the State names to be retrieved and matched with each client, within double quotation marks. In this example, enter "LabelState".

14. Double click **tFileOutputDelimited** to set its properties in the **Basic settings** tab of the **Component** view.

   a) In the **File Name field**, enter the access path and name of the output file.

   b) Click **Sync columns**, enter the access path and name of the output file.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** to run it.

**Results**

A column containing the name of the American State corresponding to each client is added to the file.
Combining two flows for selective output

In this scenario, a flow generated by `tFixedFlowInput` is combined with a flow from the Mysql database. The source flow contains `id` and `age` fields while the Mysql table contains `id` and `name`. We want to retrieve the `age` data of the source flow and combine it with the `id` and `name` records from the Mysql table based on `id` matching. One thing that is worth noting is that the input schema is different from the output one at `tMysqlRow` in the Job.

Linking the components

Procedure

1. Drop `tFixedFlowInput`, `tMysqlRow`, `tParseRecordSet` and `tLogRow` onto the workspace.
2. Rename `tFixedFlowInput` as `source_flow`, `tMysqlRow` as `insert_recordset`, `tParseRecordSet` as `parse_recordset` and `tLogRow` as `show_combined_flow`.
3. Link `tFixedFlowInput` to `tMysqlRow` using a `Row > Main` connection.
4. Link `tMysqlRow` to `tParseRecordSet` using a `Row > Main` connection.
5. Link `tParseRecordSet` to `tLogRow` using a `Row > Main` connection.

Configuring the components

Procedure

1. Double-click `tFixedFlowInput` to open its Basic settings view.
2. Select **Use Inline Content (delimited file)** in the **Mode** area.  
In the **Content** field, enter the data to be transferred:

```
1;30
2;20
```

3. Double-click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor](image)

Click the [+] button to add two columns, namely **id** and **age**, with the type of **Integer**.  
Click **Ok** to close the editor.

4. Double-click **tMysqlRow** to open its **Basic settings** view.
5. In the **Host** and **Port** fields, enter the connection details.
   In the **Database** field, enter the database name.
   In the **Username** and **Password** fields, enter the authentication details.
   In the **Query** field, enter the SQL query to retrieve the *id* and *name* data from the Mysql table `employee`: "select id, name from employee WHERE id=?".
   The question mark, "?", represents the parameter to be set in the **Advanced settings** tab.

6. Click the [...] button next to **Edit schema** to open the schema editor.

7. Click the [+] button to add two columns in the right part, namely *recordset* and *age*, with the type of **Object** and **Integer**. Note that *recordset* is intended to hold the query results of the Mysql table, namely the *id* and *name* fields.
   Click **OK** to close the editor.

8. Click the **Advanced settings** tab for further setup.
9. Select the **Propagate QUERY's recordset** check box and choose **recordset** from the **use column** list to insert the query results in that column.

Select the **Use PreparedStatement** check box and define the parameter used in the query in the **Set PreparedStatement Parameters** table.

10. Click on the [+ ] button to add a line.

   In the **Parameter Index** cell, enter the parameter position in the SQL instruction. Enter “1” as we are only using one parameter in this example.

   In the **Parameter Type** cell, enter the type of parameter. Here, the parameter is an integer. Hence, select **Int** from the list.

   In the **Parameter Value** cell, enter the parameter value. Here, we want to retrieve the **id** and **name** from the **employee** table based on the **id** value from the source flow. Hence, enter **row3.id**.

11. Double-click **tParseRecordSet** to open its **Basic settings** view.

   From the **Prev. Comp. Column list**, select the column to parse, namely **recordset**.

12. Click the [...] button next to **Edit schema** to open the schema editor.
Click the [+] button to add three columns in the right part, namely id, name and age, with the type of Integer, String and Integer. Note that the id and name fields are intended to hold the parsed data of recordset.

Click OK to close the editor.

In the Attribute table, in the Value fields which correspond to id and name, enter the name of the column in the Mysql table to be retrieved, namely “id” and “name”.

13. Double-click tLogRow to open its Basic settings view.

In the Mode area, select Table (print values in cells of a table) for better display.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 to run the Job.

```
[statistics] connecting to socket on port 4030
[statistics] connected
+-----------------------
| show_combined_flow |
| id | name | age |
+-----------------------
| 1 | Andy | 30 |
| 2 | Anderson | 20 |
+-----------------------
[statistics] disconnected
```
tMysqlSCD

Reflects and tracks changes in a dedicated MySQL SCD table.
tMysqlSCD addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

**tMysqlSCD Standard properties**

These properties are used to configure tMysqlSCD running in the Standard Job framework.
The Standard tMysqlSCD component belongs to the Business Intelligence and the Databases families.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
<td></td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
<tr>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
<td></td>
</tr>
<tr>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
<td></td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the Mysql version you are using.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>---</td>
<td>---</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
None: No operation is carried out.  
Create a table: The table does not exist and gets created.  
Create a table if not exists: The table is created if it does not exist. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. 
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in** | The schema is created and stored locally for this component only. Related topic: see **Talend Studio User Guide**. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see **Talend Studio User Guide**. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. For more information, see **SCD management methodology** on page 2511. |
| **Use memory saving mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values. |
Warning:
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected.

| Die on error | This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows. |

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>End date time details</td>
<td>Specify the time value of the SCD end date time setting in the format of HH:mm:ss. The default value for this field is 12:00:00. This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
<tr>
<td>Debug mode</td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
</tbody>
</table>

**Global Variables**

| Global Variables          | **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer. |
|                          | **NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer. |
|                          | **NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer. |
|                          | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                          | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                          | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                          | For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is used as Output component. It requires an Input component and Row main link as input. |
Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

This component does not support using SCD type 0 together with other SCD types.

SCD management methodology

Slowly Changing Dimensions (SCDs) are dimensions that change slowly over time.

The SCD editor offers the simplest method of building the data flow for the SCD outputs. In the SCD editor, you can map columns, select surrogate key columns, and set column change attributes through combining SCD types. The following figure illustrates an example of the SCD editor.
**SCD keys**

You must choose one or more source keys columns from the incoming data to ensure its unicity.

You must set one surrogate key column in the dimension table and map it to an input column in the source table. The value of the surrogate key links a record in the source to a record in the dimension table. The editor uses this mapping to locate the record in the dimension table and to determine whether a record is new or changing. The surrogate key is typically the primary key in the source, but it can be an alternate key as long as it uniquely identifies a record and its value does not change.

**Source keys**: Drag one or more columns from the Unused panel to the Source keys panel to be used as the key(s) that ensure the unicity of the incoming data.

**Surrogate keys**: Set the column where the generated surrogate key will be stored. A surrogate key can be generated based on a method selected on the Creation list.

**Creation**: Select any of the below methods to be used for the key generation.

- **Auto increment**: auto-incremental key.
- **Input field**: key is provided in an input field.

When selected, you can drag the appropriate field from the Unused panel to the complement field.
• **Routine**: from the *complement* field, you can press Ctrl+Space to display the autocompletion list and select the appropriate routine.

• **Table max +1**: the maximum value from the SCD table is incremented to create a surrogate key.

• **DB Sequence**: from the *complement* field, you can enter the name of the existing database sequence that will automatically increment the column indicated in the *name* field.

  Note that this option is only available through the SCD Editor of the tOracleSCD.

**Slowly Changing Dimensions types**

The Slowly Changing Dimensions support four types of changes: **Type 0** through **Type 3**. You can apply any of the SCD types to any column in a source table by a simple drag-and-drop operation.

• **Type 0**: is not used frequently. Some dimension data may be overwritten and other may stay unchanged over time. This is most appropriate when no effort has been made to deal with the changing dimension issues.

• **Type 1**: no history is kept in the database. New data overwrites old data. Use this type if tracking changes is not necessary. This is most appropriate when correcting certain typos, for example the spelling of a name.

• **Type 2**: the whole history is stored in the database. This type tracks historical data by inserting a new record in the dimensional table with a separate key each time a change is made. This is most appropriate to track updates, for example.

• **Type 3**: only the information about a previous value of a dimension is written into the database. This type tracks changes using separate columns. This is most appropriate to track only the previous value of a changing column.

SCD **Type 2** principle lies in the fact that a new record is added to the SCD table when changes are detected on the columns defined. Note that although several changes may be made to the same record on various columns defined as SCD **Type 2**, only one additional line tracks these changes in the SCD table.

The SCD schema in this type should include SCD-specific extra columns that hold standard log information such as:

• **start**: adds a column to your SCD schema to hold the start date. You can select one of the input schema columns as a start date in the SCD table.

• **end**: adds a column to your SCD schema to hold the end date value for a record. When the record is currently active, the end date is **NULL** or you can select **Fixed Year Value** and fill in a fictive year to avoid having a null value in the end date field.

  **Note**: The **end** column identifies active records. The surrogate ID value gets reset when the value of the **end** column changes. To avoid duplicated surrogate IDs, always make sure that the value of the **end** column remains unchanged in the target table.

• **version**: adds a column to your SCD schema to hold the version number of the record.

• **active**: adds a column to your SCD schema to hold the **true** or **false** status value. This column helps to easily spot the active record.
Tracking data changes using Slowly Changing Dimensions (type 0 through type 3)

This scenario describes a Job that stores and manages both the current and historical employee data in a MySQL table using SCD (Slowly Changing Dimensions).

The input data contains various employee details including *name*, *age*, *role*, and *salary*, and another *id* column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new MySQL table using SCD:

<table>
<thead>
<tr>
<th>id;name;age;role;salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1;Mark Smith;30;tester;11000.00</td>
</tr>
<tr>
<td>2;Thomas Johnson;32;developer;12000.00</td>
</tr>
<tr>
<td>3;Teddy Brown;33;tester;13000.00</td>
</tr>
</tbody>
</table>

Then the table is updated using SCD with the following renewed employee data.

<table>
<thead>
<tr>
<th>id;name;age;role;salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1;Mark Smith;31;tester;11000.00</td>
</tr>
<tr>
<td>2;Thomas Johnson;32;developer;12000.00</td>
</tr>
<tr>
<td>3;Teddy Brown;33;writer;13500.00</td>
</tr>
</tbody>
</table>

You can see the age of *Mark Smith* is updated from 30 to 31, the role of *Teddy Brown* is changed from *tester* to *writer*, and his salary is raised from 13000.00 to 13500.00. In this scenario,

- we don’t want to track the data changes for the *name* field, so we will perform Type 0 SCD on it,
- we want the new *age* data to overwrite the existing data, so we will perform Type 1 SCD on it,
- we want to retain the full history of the *role* data, and always create a new record with the changed data and close the previous record, so we will perform Type 2 SCD on it,
- we want to keep the current and previous dimension values for the *salary* field, so we will perform Type 3 SCD on it.

For more information about SCD types, see SCD management methodology on page 2511.

Creating a Job for tracking data changes in MySQL using SCD

Create a Job to open a connection to a MySQL database, insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions)

This Job retrieves and displays the inserted data on the console, then updates the employee data in MySQL using SCD, retrieves and displays the updated data on the console, finally closes the connection to the MySQL database.
Procedure

1. Create a new Job and add a tMysqlConnection component, two tFixedFlowInput components, two tMysqlSCD components, two tMysqlInput components, two tLogRow components, and a tMysqlClose component by typing their names in the design workspace or dropping them from the Palette.

2. Link the first tFixedFlowInput component to the first tMysqlSCD component using a Row > Main connection.

3. Do the same to link the first tMysqlInput component to the first tLogRow component, the second tFixedFlowInput component to the second tMysqlSCD component, and the second tMysqlInput component to the second tLogRow component.

4. Link the tMysqlConnection component to the first tFixedFlowInput component using a Trigger > OnSubjobOk connection.

5. Do the same to link the first tFixedFlowInput component to the first tMysqlInput component, the first tMysqlInput component to the second tFixedFlowInput component, the second tFixedFlowInput component to the second tMysqlInput component, and the second tMysqlInput component to the tMysqlClose component.
Opening a connection to a MySQL database

Configure the `tMysqlConnection` component to open a connection to a MySQL database.

**Procedure**

1. Double-click the `tMysqlConnection` component to open its **Basic settings** view.

2. In the **Host**, **Port**, **Database**, **Username**, and **Password** fields, enter the information required for the connection to the MySQL database.

Inserting the employee data into a MySQL table using SCD

Configure the first `tFixedFlowInput` component and the first `tMysqlSCD` component to insert the employee data into a MySQL database table using SCD (Slowly Changing Dimensions).

**Procedure**

1. Double-click the first `tFixedFlowInput` component to open its **Basic settings** view.

2. Click the button next to **Edit schema** and in the pop-up window define the schema by adding five columns: `id` and `age` of Integer type, `name` and `role` of String type, and `salary` of Double type.
When done, click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

3. In the **Mode** area, select **Use Inline Content (delimited file)**. Then in the **Content** field displayed, enter the following input employee data.

```
1;Mark Smith;30;tester;11000.00
2;Thomas Johnson;32;developer;12000.00
3;Teddy Brown;33;tester;13000.00
```

4. Click the first **tMysqlSCD** component to open its **Basic settings** view.

5. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component you have configured.

6. In the **Table** field, enter the name of **employee_scd**.

7. Click the **button next to SCD Editor** to open the SCD editor. All schema columns are listed on the **Unused** panel.

8. In the **name** field on the **Surrogate keys** panel, enter the name for the surrogate key, **SK** in this example.

9. From the **Unused** panel, drag and drop
   - **id** to the **Source keys** panel to use it as the key to ensure the unicity of the input data,
   - **name** to the **Type 0 fields** panel and no special action will be performed upon dimension changes of it,
- age to the **Type 1 fields** panel to perform Type 1 SCD on it,
- role to the **Type 2 fields** panel to perform Type 2 SCD on it, and
- salary to the **Type 3 fields** panel to perform Type 3 SCD on it.

10. In the **Versioning** panel, select the **version** check box to hold the version numbers for the historical and current records in the SCD table, and select also the **active** check box to add the column that will hold the **True** value for the current active record or the **False** value for the historical records in the SCD table.

When done, click **OK** to save the changes and close the SCD editor.

**Retrieving the inserted employee data from MySQL**

Configure the first **tMysqlInput** component and the first **tLogRow** component to retrieve the inserted employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component you have configured.

3. In the **Table Name** field, enter the name of the table from which the employee data will be retrieved. In this example, it is `employee_scd`.

4. Open the schema editor of the **tMysqlSCD** component, select and copy all its schema columns, then open the schema editor of the **tMysqlInput** component, define its schema by pasting those schema columns you have copied from the **tMysqlSCD** component.

When done, click **OK** to save the changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

5. Click the **Guess Query** button to fill the **Query** field with the automatically generated SQL query that will extract data of all columns from the specified table.
6. Double-click the first tLogRow component to open its Basic settings view. In the Mode area, select Table (print values in cells of a table) for better readability of the result displayed on the console.

**Updating the employee data in MySQL using SCD**

Configure the second tFixedFlowInput component and the second tMysqlSCD component to update the employee data in MySQL using SCD (Slowly Changing Dimensions).

**Procedure**

1. Double-click the second tFixedFlowInput component to open its Basic settings view.
2. Click the button next to Edit schema and in the pop-up window define the schema by copying and pasting the schema of the first tFixedFlowInput component.
3. In the Mode area, select Use Inline Content (delimited file). Then in the Content field displayed, enter the following updated employee data.

```
1;Mark Smith;31;tester;11000.00
2;Thomas Johnson;32;developer;12000.00
3;Teddy Brown;33;writer;13500.00
```
4. Repeat 4 on page 2517 through 10 on page 2518 in the procedure Inserting the employee data into a MySQL table using SCD on page 2516 to configure the second tMysqlSCD component.

**Retrieving the updated employee data from MySQL**

Configure the second tMysqlInput component and the second tLogRow component to retrieve the updated employee data from the MySQL SCD table and display it on the console.

**Procedure**

1. Repeat 1 on page 2518 through 5 on page 2519 in the procedure Retrieving the inserted employee data from MySQL on page 2518 to configure the second tMysqlInput component.
2. Repeat 6 on page 2520 in the procedure Retrieving the inserted employee data from MySQL on page 2518 to configure the second tLogRow component.

**Closing the connection to the MySQL database**

Configure the tMysqlClose component to close the connection to the MySQL database.

**Procedure**

1. Double-click the tMysqlClose component to open its Basic settings view.
2. From the Component List drop-down list, select the connection component that opens the connection you want to close. In this example, it is tMysqlConnection_1.

**Executing the Job to track data changes in MySQL using SCD**

After setting up the Job and configuring the components used in the Job for tracking data changes in MySQL using SCD, you can then execute the Job and verify the Job execution result.

**Procedure**

1. Press Ctrl + S to save the Job.
2. Press F6 to execute the Job.

As shown above, the new age data 31 for Mark Smith the old age data 30, a new record with the SK value set to 4 is created for the role change for Teddy Brown from tester to writer, and the values of the previous salary and the current salary for Teddy Brown are both kept in the newly created record.
**tMysqlSCDELT**

Reflects and tracks changes in a dedicated MySQL SCD table through SQL queries.

`tMysqlSCDELT` addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated MySQL SCD table.

**tMysqlSCDELT Standard properties**

These properties are used to configure `tMysqlSCDELT` running in the Standard Job framework.

The Standard `tMysqlSCDELT` component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong></td>
<td>No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td><strong>Repository:</strong></td>
<td>Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>DB Version</td>
<td>Select the Mysql version you are using.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

---

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>The IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication data for a dedicated database. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Source table</strong></td>
<td>Name of the input MySQL SCD table.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | Select to perform one of the following operations on the table defined:  
   - **None**: No action carried out on the table.  
   - **Drop and create the table**: The table is removed and created again  
   - **Create a table**: A new table gets created.  
   - **Create a table if not exists**: A table gets created if it does not exist.  
   - **Clear a table**: The table content is deleted. You have the possibility to rollback the operation.  
   - **Truncate a table**: The table content is deleted. You do not have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
   Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
   - **View schema**: choose this option to view the schema only.  
   - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
   - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
   - **Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.  
   - **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |
## Surrogate Key
Select the surrogate key column from the list.

## Creation
Select the method to be used for the surrogate key generation.
For more information regarding the creation methods, see SCD management methodology on page 2511.

## Source Keys
Select one or more columns to be used as keys, to ensure the unicity of incoming data.

## Use SCD Type 1 fields
Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

## Use SCD Type 2 fields
Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

## SCD type 2 fields
Click the `[+]` button to add as many rows as needed, each row for a column. Click the arrow on the right side of the cell and select the column whose value changes will be tracked using Type 2 SCD from the drop-down list displayed.
This table is available only when the Use SCD type 2 fields option is selected.

## Start date
Specify the column that holds the start date for type 2 SCD.
This list is available only when the Use SCD type 2 fields option is selected.

## End date
Specify the column that holds the end date for type 2 SCD.
This list is available only when the Use SCD type 2 fields option is selected.

### Note:
To avoid duplicated change records, it is recommended to select a column that can identify each change for this field.

## Log active status
Select this check box and from the Active field drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD.
This option is available only when the Use SCD type 2 fields option is selected.

## Log versions
Select this check box and from the Version field drop-down list displayed, select the column that holds the version number of the record for type 2 SCD.
This option is available only when the Use SCD type 2 fields option is selected.

## Advanced settings

### Debug mode
Select this check box to display each step during processing entries in a database.
tStat Catcher Statistics

Select this check box to collect log data at the component level.

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. 

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component is used as an output component. It requires an input component and Row main link as input. |

Dynamic settings

| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related Scenarios

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1879.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 2948.
tMysqlSP

Calls a MySQL database stored procedure.

tMysqlSP offers a convenient way to centralize multiple or complex queries in a database and call them easily.

**tMysqlSP Standard properties**

These properties are used to configure tMysqlSP running in the Standard Job framework.

The Standard tMysqlSP component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>SP Name</th>
<th>Type in the exact name of the Stored Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Is Function / Return result in</td>
<td>Select this check box, if a value only is to be returned. Select on the list the schema column, the value to be returned is based on.</td>
</tr>
</tbody>
</table>
| Parameters | Click the Plus button and select the various **Schema Columns** that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure. Select the **Type** of parameter:
- **IN**: Input parameter.
- **OUT**: Output parameter/return value.
- **IN OUT**: Input parameters is to be returned as value, likely after modification through the procedure (function).
- **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value. |

**Usage**

| Usage rule | This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic** |

**Note:**

Check **Inserting data in mother/daughter tables** on page 2426 if you want to analyze a set of records from a database table or DB query and return single records.
settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | The Stored Procedures syntax should match the Database syntax. |

Using tMysqlSP to find a State Label using a stored procedure

The following job aims at finding the State labels matching the odd State IDs in a Mysql two-column table. A stored procedure is used to carry out this operation.

- Drag and drop the following components used in this example: tRowGenerator, tMysqlSP, tLogRow.
- Connect the components using the Row Main link.
- The tRowGenerator is used to generate the odd id number. Double-click on the component to launch the editor.

- Click on the Plus button to add a column to the schema to generate.
- Select the Key check box and define the Type to Int.
- The Length equals to 2 digits max.
• Use the preset function called **sequence** but customize the Parameters in the lower part of the window.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Length</th>
<th>Functions</th>
<th>Parameters</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
<td></td>
<td>int</td>
<td></td>
<td>Z</td>
<td>sequence</td>
<td>sequence i...</td>
</tr>
</tbody>
</table>

Function parameters

Parameter | Value | Comment |
---|---|---|
sequence identifier | 's!' | |
start value | 1 | |
step | 2 | |

• Change the **Value** of **step** from 1 to 2 for this example, still starting from 1.
• Set the **Number of generated rows** to 25 in order for all the odd State id (of 50 states) to be generated.
• Click **OK** to validate the configuration.
• Then select the **tMysqlSP** component and define its properties.

**tMysqlSP_1**

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Built-In</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>DB Version</th>
<th>Mysql 5</th>
</tr>
</thead>
</table>

**Dynamic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Host</th>
<th>Port</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>&quot;localhost&quot;</td>
<td>&quot;3306&quot;</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Database</th>
<th>&quot;taend&quot;</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Username</th>
<th>Password</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;root&quot;</td>
<td>&quot;********&quot;</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Schema</th>
<th>Built-In</th>
<th>Edit scheme</th>
<th>Sync columns</th>
</tr>

</tr>
</thead>
<tbody>
<tr>
<td>Schema Column</td>
<td>Type</td>
</tr>
<tr>
<td>ID</td>
<td>IN</td>
</tr>
<tr>
<td>State</td>
<td>OUT</td>
</tr>
</tbody>
</table>

• Set the **Property type** field to **Repository** and select the relevant entry on the list. The connection details get filled in automatically.
• Else, set manually the connection information.
• Click **Sync Column** to retrieve the generated schema from the preceding component.
• Then click **Edit Schema** and add an extra column to hold the State Label to be output, in addition to the ID.
• Type in the name of the procedure in the **SP Name** field as it is called in the Database. In this example, *getstate*. The procedure to be executed states as follows:

```
DROP PROCEDURE IF EXISTS `talend`.`getstate` $$
CREATE DEFINER=`root`@`localhost` PROCEDURE `getstate`(IN pid INT, OUT pstate VARCHAR(50))
BEGIN
  SELECT LabelState INTO pstate FROM us_states WHERE idState = pid;
END $$
```

• In the **Parameters** area, click the plus button to add a line to the table.
• Set the **Column** field to *ID*, and the **Type** field to *IN* as it will be given as input parameter to the procedure.
• Add a second line and set the **Column** field to *State* and the **Type** to *Out* as this is the output parameter to be returned.
• Eventually, set the **tLogRow** component properties.

```
Starting job MysqlSP at 17:24 23/08/2007
<table>
<thead>
<tr>
<th>ID</th>
<th>State</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Alabama</td>
</tr>
<tr>
<td>3</td>
<td>Arizona</td>
</tr>
<tr>
<td>5</td>
<td>California</td>
</tr>
<tr>
<td>7</td>
<td>Connecticut</td>
</tr>
<tr>
<td>9</td>
<td>Florida</td>
</tr>
<tr>

</tr>
<tr>
<td>29</td>
<td>New Hampshire</td>
</tr>
<tr>
<td>31</td>
<td>New Mexico</td>
</tr>
<tr>
<td>33</td>
<td>North Carolina</td>
</tr>
</tbody>
</table>
```

The output shows the state labels corresponding to the odd state ids as defined in the procedure.
Note:
Check Inserting data in mother/daughter tables on page 2426 if you want to analyze a set of records from a database table or DB query and return single records.

Related scenarios

For related scenarios, see:

- Retrieving personal information using a stored procedure on page 2404.
- Checking number format using a stored procedure on page 2735.
- Executing a stored procedure using tMDMSP on page 2180.
**tMysqlTableList**

Lists the names of a given set of Mysql tables using a select statement based on a Where clause. tMysqlTableList iterates on a set of table names through a defined Mysql connection.

**tMysqlTableList Standard properties**

These properties are used to configure tMysqlTableList running in the Standard Job framework. The Standard tMysqlTableList component belongs to the Databases family. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tMysqlConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the Where clause to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

### Advanced settings

| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

**Global Variables**

- **CURRENT_TABLE:** the name of the table currently iterated upon. This is a Flow variable and it returns a string.
- **NB_TABLE:** the number of tables iterated upon so far. This is a Flow variable and it returns an integer.
- **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with Mysql components, especially with tMysqlConnection.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your job settings, for example, when your job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2446 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

**Iterating on DB tables and deleting their content using a user-defined SQL template**

The following Java scenario creates a three-component job that iterates on given table names from a MySQL database using a WHERE clause. It then deletes the content of the tables directly on the DBMS using a user-defined SQL template.

For advanced use, start with creating a connection to the database that contains the tables you want to empty of their content:

- In the **Repository** tree view, expand **Metadata** and right click **DB Connections** to create a connection to the relevant database and to store the connection information locally.

  For more information about Metadata, see Talend Studio User Guide.

Otherwise, drop a tMySQLConnection component in the design workspace and fill the connection details manually.

- Drop the database connection you created from the **Repository** onto the design workspace.

  The **Components** dialog box displays.

- Select **tMySQLConnection** and click **OK**.

  The **tMySQLConnection** components displays on the design workspace with all connection details automatically filled in its **Basic settings** view.

- Drop the following two components from the **Palette** onto the design workspace: **tMysqlTableList** and **tELT**.

- Connect **tMySQLConnection** to **tMysqlTableList** using an **OnSubjobOk** link.
• Connect tMysqlTableList to tELT using an Iterate link.
• If needed, double-click tMysqlConnection to display its Basic settings view and verify the connection details.

In this example, we want to connect to a MySQL database called examples.

• In the design workspace, double-click tMysqlTableList to display its Basic settings view and define its settings.

• On the Component list, select the relevant MySQL connection component if more than one connection is used.
• Enter a WHERE clause using the right syntax in the corresponding field to iterate on the table name(s) you want to delete the content of.

In this scenario, we want the job to iterate on all the tables which names start with "ex".

• In the design workspace, double-click tELT to display its Basic settings view and define its settings.
In **Database Name**, enter the name of the database containing the tables you want to process.

On the **Component list**, select the relevant MySQL connection component if more than one connection is used.

Click in the **Table name** field and press **Ctrl+Space** to access the global variable list.

From the global variable list, select `((String)globalMap.get("tMysqlTableList_1_CURRENT_TABLE"))`.

**To create the user-defined SQL template:**

- In the **Repository** tree view, expand **SQL Templates** and **MySQL** in succession.
  - Right-click **UserDefined** and select **Create SQLTemplate** from the drop-down list.
    
    The **New SQLTemplate** wizard opens.
• Enter a name for the new SQL template and fill in the other fields if needed and then click **Finish** to close the wizard.

An SQL pattern editor opens on the design workspace.

• Delete the existing code and enter the code necessary to carry out the desired action, deleting the content of all tables which names start with "ex" in this example.

Note:
In the SQL template code, you must use the correct variable name attached to the table name parameter ("__TABLE_NAME__" in this example). To display the variable name used, put your pointer in the **Table Name** field in the basic settings of the **tELT** component.

• Press **Ctrl+S** to save the new user-defined SQL template.

The next step is to add the new user-defined SQL template to the SQL template list in the **tELT** component.

To add the user-defined SQL template to the SQL template list:
• In the Component view of tELT, click the SQL Templates tab to display the SQLTemplate List.

• Click the Add button and add two SQL template lines.
• Click in the first line to display a drop-down arrow and then click the arrow to display the SQL template list.

• Select in the list the user-defined SQL template you already created.
• Make sure that the SQL template in the second line is Commit.
• Save your job and press F6 to execute it.

All tables in the MySQL examples database which names begin with "ex" are emptied from their content.

Related scenario

For tMysqlTableList related scenario, see Iterating on a DB table and listing its column names on page 2419.
tNamedPipeClose

Closes a named-pipe at the end of a process.
tNamedPipeClose closes a named-pipe opened with tNamedPipeOpen at the end of a process.

**tNamedPipeClose Standard properties**

These properties are used to configure tNamedPipeClose running in the Standard Job framework. The Standard tNamedPipeClose component belongs to the File family. The component in this framework is available in all Talend products.

**Basic settings**

| Pipe | Select an existing named-pipe from the list to close. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see [Talend Studio User Guide](https://help.talend.com). |

**Usage**

| Usage rule | This component is usually used to close a named-pipe at the end of a Job. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job. When a dynamic parameter is defined, the Pipe box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic](https://help.talend.com). |
connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenario**

For a related scenario, see Writing and loading data through a named-pipe.
tNamedPipeOpen

Opens a named-pipe for writing data into it.
Used in inner-process communication, tNamedPipeOpen opens a named-pipe for writing data into it.

**tNamedPipeOpen Standard properties**

These properties are used to configure tNamedPipeOpen running in the Standard Job framework.
The Standard tNamedPipeOpen component belongs to the File family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Name</th>
<th>Fill in the field with the name of the named-pipe.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete if already exist</td>
<td>Select this check box to avoid duplicate named-pipe.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | PIPE_NAME: the name of the named-pipe. This is a Flow variable and it returns a string. |
|------------------| PIPE_NATIVE_NAME: the native name of the named-pipe. This is a Flow variable and it returns a string. |
|                  | PIPE_OUTPUTSTREAM: the output stream of the named-pipe. This is a Flow variable and it returns an object. |
|                  | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| Usage rule | This component is usually used as the starting component in an inner-process communication Job. |
| Limitation                                                                 | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenario**

For a related scenario, see Writing and loading data through a named-pipe.
tNamedPipeOutput

Writes data into an existing open named-pipe.
tNamedPipeOutput writes data into a named-pipe opened with tNamedPipeOpen.

tNamedPipeOutput Standard properties

These properties are used to configure tNamedPipeOutput running in the Standard Job framework.
The Standard tNamedPipeOutput component belongs to the File family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Use existing pipe connection</th>
<th>Select this check box to use an existing named-pipe in the Pipe component list, or clear this check box to specify a named-pipe in Pipe name field.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Pipe component</td>
<td>Select an existing named-pipe component from the list.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This check box will display only when you select Use existing pipe connection.</td>
</tr>
<tr>
<td>Pipe name</td>
<td>Fill in the field with the name of an existing named-pipe.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>This check box will display only when you clear Use existing pipe connection.</td>
</tr>
<tr>
<td>Row separator</td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows in the output file.</td>
</tr>
<tr>
<td>Field separator</td>
<td>Character, string or regular expression to separate fields of the output file.</td>
</tr>
<tr>
<td>CSV options</td>
<td>Select this check box to take into account all parameters specific to CSV files, in particular Escape char and Text enclosure parameters.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td><strong>View schema:</strong></td>
<td>choose this option to view the schema only.</td>
</tr>
<tr>
<td><strong>Change to built-in property:</strong></td>
<td>choose this option to change the schema to Built-in for local changes.</td>
</tr>
</tbody>
</table>
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the Repository Content window.

  Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

  - **Built-in**: The schema will be created and stored locally for this component only. Related topic: see **Talend Studio User Guide**.

  - **Repository**: The schema already exists and is stored in the Repository, hence can be reused in various projects and Job flowcharts. Related topic: see **Talend Studio User Guide**.

  **Delete pipe if it exists**

  Select this check box to avoid duplicate named-pipe.

### Advanced settings

<table>
<thead>

</table>

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

  To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

  For further information about variables, see **Talend Studio User Guide**.
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is usually connected to another component in a subjob that reads data from a source.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your pipe connection dynamically from multiple connections planned in your Job.  

The **Dynamic settings** table is available only when the **Use existing pipe connection** check box is selected in the **Basic settings** view. When a dynamic parameter is defined, the **Pipe component** list box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see *Reading data from databases through context-based dynamic connections* on page 2446 and *Reading data from different MySQL databases using dynamically loaded connection parameters* on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |
tNeo4jBatchOutput

Receives data from the preceding component and writes the data into a local Neo4j database. tNeo4jBatchOutput is used to write nodes in a Neo4j database based on the defined index.

**tNeo4jBatchOutput Standard properties**

These properties are used to configure tNeo4jBatchOutput running in the Standard Job framework. The Standard tNeo4jBatchOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Field that contains the label list</th>
<th>Select the column from the input schema you have defined in the preceding components to provide labels for the nodes to be created. When the input data provides multiple labels for a node, separate those labels by semi-colons (;) in the preceding components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database path</td>
<td>Specify the directory to hold your data files. If the specified directory does not exist, it will be created. This field appears only if you do not select the <strong>Use an existing connection</strong> check box.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the <strong>Remote server</strong> check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.</td>
</tr>
<tr>
<td>Shutdown after job</td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as ‘I’d file not properly shutdown’ at next execution of Jobs involving Neo4j. This check box is available only if the <strong>Use an existing connection</strong> check box is not selected.</td>
</tr>
</tbody>
</table>

| Index name                        | Enter, within double quotation marks, the name of the index to be created for the nodes. This index is used to store the identifiers of the nodes and help create relationships. |
### Import identifier

Select the column from the input schema you have defined in the preceding components to provide identifiers for the nodes to be created. These identifiers are stored in the index to be created and must be unique cross the index. Therefore, ensure that the column to be used contains only unique values.

### Save the identifier

Select this check box to save the technical identifiers (native graph ids).

For further information about the different types of Neo4j entity identifiers, see Neo4j documentation: Entity identifier.

### Number of index elements in memory

Enter, without double quotation marks, the cache size used to keep the index elements in memory. This value must be enough to keep all of the index elements in memory.

For further information, see Neo4j documentation: Memory tuning.

---

## Advanced settings

### Neo4j configuration

Add parameters to the table to configure the database to be created.

For further information, see Neo4j documentation: Configuration settings.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

## Global Variables

### Global Variables

**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.
## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component and it always needs an incoming link.</th>
</tr>
</thead>
</table>
tNeo4jBatchOutputRelationship

Receives data from the preceding component and writes relationships in bulk into a local Neo4j database.

**tNeo4jBatchOutputRelationship Standard properties**

These properties are used to configure tNeo4jBatchOutputRelationship running in the Standard Job framework.

The Standard tNeo4jBatchOutputRelationship component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database path</strong></td>
<td>Specify the directory to hold your data files. This field appears only if you do not select the Use an existing connection check box.</td>
</tr>
<tr>
<td><strong>Shutdown after job</strong></td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as 'Id file not properly shutdown' at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected.</td>
</tr>
<tr>
<td><strong>Field for relationship types</strong></td>
<td>Select the column from the input schema you have defined in the preceding components to provide types for the relationships to be created.</td>
</tr>
</tbody>
</table>
| **Direction of the relationship** | Select the direction of the relationships to be created:  
  - **Outgoing**: The relationship starts from the start node to the end node.  
  - **Incoming**: The relationship starts from the end node to the start node. |
| Start node of the relationship | Defining the start node of each relationship using the node identifier:  
|                              | • **Name of the batch index**: select the tNeo4jBatchOutput component used to create the start nodes. The name of the index for these nodes are retrieved from that component.  
|                              | • **Field name for the batch index**: select the column from the input schema you have defined in the preceding components to provide the name of the start node of each relationship to be created. |
| End node of the relationship  | Defining the end node of each relationship using the node identifier:  
|                              | • **Name of the batch index**: select the tNeo4jBatchOutput component used to create the end nodes. The name of the index for these nodes are retrieved from that component.  
|                              | • **Field name for the batch index**: select the column from the input schema you have defined in the preceding components to provide the name of the end node of each relationship to be created. |
| Die on error                 | Select the check box to stop the execution of the Job when an error occurs.  
|                              | Clear the check box to skip any rows on error and complete the process for error-free rows. |

### Advanced settings

| Neo4j configuration | Add parameters to the table to configure the database to be created.  
|                    | For further information, see Neo4j documentation: [Configuration settings](#).  
| tStatCatcher Statistics | When entering values, use the syntax demonstrated by the examples given alongside the column names of this **Nodes files** table. |
| Global Variables    | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
|                 | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
|                 | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component is used as an output component and it always needs an incoming link. |

### Writing information of actors and movies to Neo4j with hierarchical relationship using Neo4j Batch components

In this scenario, Neo4j Batch components are used to import data about actors and movies from two CSV files in a local Neo4j database and create relationship for the data based on another CSV file that describes the actors' roles in the movies.

This scenario applies only to Talend products with Big Data.

The Neo4j Batch components provided by Talend supports bulk writing to a local Neo4j database only. They can be used neither with Neo4j versions prior to V3.2.X nor alongside Neo4j components that are using one of those Neo4j versions.

The components to be used are:

- One tNeo4jConnection component: it opens the connection to Neo4j to be reused.
- Three tFileInputDelimited components: they read the input information of actors and movies.
- Two tNeo4jBatchOutput components: they write information of movies and actors to the connected Neo4j database.
- One tNeo4jBatchOutputRelationship component: it creates relationship between actors and movies.
- One tNeo4jBatchSchema component: it creates an uniqueness constraint on the nodes in the database.
Creating the Neo4j Batch Job

Procedure

1. Ensure that the status of your Neo4j service and Neo4j console is stop.
   If you are using command-line to manage Neo4j, you can use neo4j status to check the status; if you have installed the Neo4j desktop application, you can check it directly in this application.

2. From the Repository on the Integration perspective, create a Job and add the components to be used by typing their names in the design workspace or dropping them from the Palette.

3. Connect the first tFileInputDelimited component to the first tNeo4jBatchOutput component using a Row > Main link. This subJob imports the actors data in the Neo4j database.

4. Connect the second tFileInputDelimited component to the second tNeo4jBatchOutput component using a Row > Main link. This subJob imports the movies data in the Neo4j database.

5. Connect the third tFileInputDelimited component to the tNeo4jBatchOutputRelationship component using a Row > Main link. This subJob creates relationship between actors and movies.

6. Connect the subJobs using Trigger > On Subjob Ok links.

Configuring the Neo4j connection to be reused

Procedure

1. Double-click the tNeo4jConnection component to open its Basic settings view.
2. From the **DB Version** list, select **Neo4J 3.2.X**.

3. Ensure that the **Use a remote server** check box is clear because that the Neo4j Batch components work only on the local mode.

4. In the **Database path** field, enter the path or browse to the database file.

**Bulk-writing the actors data in Neo4j**

**Procedure**

1. Double-click the first **tFileInputDelimited** component to open its **Component** view.

2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the actors’ IDs, names and their labels to be used in Neo4j.

   The input CSV file used in this example reads as follows:

   ```
   keanu,"Keanu Reeves",Actor
   laurence,"Laurence Fishburne",Actor
   carrieanne,"Carrie-Anne Moss",Actor
   ```

   The double quotation marks on the actor names are not mandatory.

3. Click the [...] button next to **Edit schema** to open the schema editor, and define the input schema based on the structure of the input file.

   In this example, the columns are **id**, **name** and **label**, all of type **String**.
4. Click OK to close this editor and accept the propagation of the schema to the next component.
5. In the Field separator field, enter a comma (,) to replace the default semicolon (;).
6. Double-click the first tNeo4jBatchOutput component to open its Component view.

7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.
8. Verify that the **Shutdown after Job** check box is clear.
9. From the Field that contains the label list drop-down list, select the column that provides labels.
10. In the **Index name** field, enter the name of the index to be created for the nodes.
11. From Import identifier drop-down list, select the column that provides IDs.

**Bulk-writing the movies data into Neo4j**

**Procedure**

1. Double-click the second tFileInputDelimited component to open its Component view.
2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the movies' IDs, names, release years and their labels to be used in Neo4j.

The input CSV file used in this example reads as follows:

```
tt0133093,"The Matrix",1999,Movie
tt0234215,"The Matrix Reloaded",2003,Movie;Sequel
tt0242653,"The Matrix Revolutions",2003,Movie;Sequel
```

The double quotation marks on the movie names are not mandate.

3. Click the [...] button next to **Edit schema** to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are **id**, **title**, **released** and **label**.

4. Click **OK** to close this editor and accept the propagation of the schema to the next component.

5. In the **Field separator** field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the second **tNeo4jBatchOutput** component to open its **Component** view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field that contains the label list** drop-down list, select the column that provides labels.

10. In the **Index name** field, enter the name of the index to be created for the nodes.

11. From **Import identifier** drop-down list, select the column that provides IDs.

**Creating relationships in bulk**

**Procedure**

1. Double-click the third **tFileInputDelimited** component to open its **Component** view.

2. In the **File name/Stream** field, enter the path or browse to the CSV file that describes the actor-movie relationships.
The input CSV file used in this example reads as follows:

<table>
<thead>
<tr>
<th>from</th>
<th>role</th>
<th>to</th>
<th>type</th>
</tr>
</thead>
<tbody>
<tr>
<td>keanu</td>
<td>&quot;Neo&quot;</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>keanu</td>
<td>&quot;Neo&quot;</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>keanu</td>
<td>&quot;Neo&quot;</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>&quot;Morpheus&quot;</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>&quot;Morpheus&quot;</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>laurence</td>
<td>&quot;Morpheus&quot;</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>&quot;Trinity&quot;</td>
<td>tt0133093</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>&quot;Trinity&quot;</td>
<td>tt0234215</td>
<td>ACTED_IN</td>
</tr>
<tr>
<td>carrieanne</td>
<td>&quot;Trinity&quot;</td>
<td>tt0242653</td>
<td>ACTED_IN</td>
</tr>
</tbody>
</table>

The double quotation marks on the role names are not mandatory. The value ACTED_IN is an user-defined relationship type that explains the relationship between the actors and the movies.

3. Click the [...] button next to Edit schema to open the schema editor, and define the input schema based on the structure of the input file.

In this example, the columns are from, role, to and type.

4. Click OK to close this editor and accept the propagation of the schema to the next component.

5. In the Field separator field, enter a comma (,) to replace the default semicolon (;).

6. Double-click the tNeo4jBatchOutputRelationship component to open its Component view.
7. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

8. Verify that the **Shutdown after Job** check box is clear.

9. From the **Field for relationship type** drop-down list, select the column that provides the relationship types.

10. From the **Direction of the relationship** drop-down list, select **Outgoing**.

11. In the **Start node of the relationship** area, select the tNeo4jBatchOutput component that provides the index of the start nodes, which is the `asActors` index in this example from the first tNeo4jBatchOutput. Then from the **Field name for the batch index** drop-down list, select the column that provides the actor names as the start nodes.

12. Repeat this action in the **End node of the relationship** area to select the `asMovie` index from the second tNeo4jBatchOutput and then select the column that provides the movie names as the end nodes.

**Adding uniqueness constraints on the nodes**

**Procedure**

1. Double-click the tNeo4jBatchSchema component to open its **Component** view.
2. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the tNeo4jConnection component.

3. Select the **Shutdown after Job** check box to properly close the connection after the execution.

4. In the **Schema definition** table, add two rows by clicking the [+] button twice:
   
   a) In the **Schema type** column, select **Node property is unique** for both of the rows to add uniqueness constraints to nodes in Neo4j.
   
   b) In the **For node with Label** column, enter, within double quotation marks, **Actor** and **Movie** respectively, which are the labels used by the actor nodes and the movie nodes. Therefore, what you enter here must be identical with the labels previously used when creating those nodes.
   
   c) In the **On property** column, enter, within double quotation marks, the node properties to which you need to add uniqueness constraints. For the actor nodes, enter **name** and for the movie nodes, enter **title**. The values you enter here must be identical with the column names previously defined to provide actor names and movie names for the nodes to be created by the tNeo4jBatchOutput components.

5. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to execute the Job.

**Results**

Once the Job runs successfully to the end, check the result in your Neo4j browser:
tNeo4jBatchSchema

Defines the schema of a local Neo4j database.

**tNeo4jBatchSchema Standard properties**

These properties are used to configure tNeo4jBatchSchema running in the Standard Job framework.

The Standard tNeo4jBatchSchema component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. This component supports Neo4j version V3.2.X only and does not support the remote mode. Therefore, do not reuse the connection to versions other than V3.2.X defined in a tNeo4jConnection component and do not select the Remote server check box in tNeo4jConnection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database path</td>
<td>Specify the directory to hold your data files. If the specified directory does not exist, it will be created. This field appears only if you do not select the Use an existing connection check box.</td>
</tr>
<tr>
<td>Shutdown after job</td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected.</td>
</tr>
<tr>
<td>Schema definition</td>
<td>Add indexes and unique property constraints to define the schema: • <strong>Schema type:</strong> select whether it is an index (Index on node property) or a constraint (Node property is unique) to be defined. • <strong>For node with label:</strong> enter, within double quotation marks, the label of a node. • <strong>On property:</strong> enter, within double quotation marks, the property of a node.</td>
</tr>
</tbody>
</table>
### Advanced settings

| Neo4j configuration | Add parameters to the table to configure the database to be created.
For further information, see Neo4j documentation: [Configuration settings](#).
When entering values, use the syntax demonstrated by the examples given alongside the column names of this **Nodes files** table. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Global Variables

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

### Usage

| Usage rule | This component is used standalone in a subjob to write a Neo4j graph schema. |
tNeo4jClose

Close an active connection to an Neo4j database in embedded mode.

**tNeo4jClose Standard properties**

These properties are used to configure tNeo4jClose running in the Standard Job framework. The Standard tNeo4jClose component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

| Connection | Select an active Neo4j database connection to be closed. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is to be used along with other Neo4j components, especially with tNeo4jConnection. |

| Limitation | n/a |

**Related scenarios**

For scenario in which tNeo4jClose is used, see:

- Writing information of actors and movies to Neo4j with hierarchical relationship on page 2589,
• Creating nodes with a label using a Cypher query on page 2602, and
• Importing data from a CSV file to Neo4j using a Cypher query on page 2606.
tNeo4jConnection

Opens a connection to a Neo4j database to be reused by other Neo4j components.
tNeo4jConnection starts the database in embedded mode, and checks the server availability in REST mode.

tNeo4jConnection Standard properties

These properties are used to configure tNeo4jConnection running in the Standard Job framework.
The Standard tNeo4jConnection component belongs to the Big Data and the Databases NoSQL families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| DB version | Select the Neo4j version you are using. When you use V3.2.X:
|            | • If you work with a remote server, only tNeo4jInput and tNeo4jRow can reuse the connection defined in tNeo4jConnection because these components work with Neo4j remote servers only.
|            | • If you work with a local server, only tNeo4jBatchOutput, tNeo4jBatchSchema and tNeo4jBatchOut putRelationship can reuse the connection defined in tNeo4jConnection because these components work with Neo4j local servers only.
|            | Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.
|            | Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.
|            | Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

| Remote server | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.
|              | • Set username: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.
|              | • Username and Password: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.

| Server URL | Specify the root URL. |
**tNeo4jConnection**

This field is available only if the **Use a remote server** check box is selected.

### Read only

Select this check box if you want to use the embedded database in read only mode. It’s useful if an application is already dedicated with the database.

This check box is available only when you are using a 2.X.X version.

**Warning:**

Do not use this mode when you have any output Neo4j component in your Job such as **tNeo4jOutput**, **tNeo4jOutputRelationship** or **tNeo4jRow**.

### Database path

If you use Neo4j in embedded mode, specify the path of data file.

This field is available only if the **Use a remote server** check box is not selected.

### Advanced settings

**tStatCatcher Statistics**

Select this check box to collect the log data at a component level.

### Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

**Usage rule**

This component is generally used with other Neo4j components, particularly **tNeo4jClose**.

**Limitation**

n/a

### Related scenarios

For scenario in which **tNeo4jConnection** is used, see:

- [Writing information of actors and movies to Neo4j with hierarchical relationship](#) on page 2589,
• Creating nodes with a label using a Cypher query on page 2602, and
• Importing data from a CSV file to Neo4j using a Cypher query on page 2606.
tNeo4jImportTool

Uses Neo4j Import Tool to create a Neo4j database and import large amounts of data in bulk from CSV files to this database.

tNeo4jImportTool Standard properties

These properties are used to configure tNeo4jImportTool running in the Standard Job framework.

The Standard tNeo4jImportTool component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

<table>
<thead>
<tr>
<th>Neo4j database folder</th>
<th>Enter, or browse to the directory you want tNeo4jImportTool to create a Neo4j database. The name you put in the path is used to name this database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes files</td>
<td>Complete this table to provide the CSV files that contain the information about the nodes to be imported.</td>
</tr>
<tr>
<td></td>
<td>• Path to CSV file: enter, within double quotation marks, the path to the CSV file to be read.</td>
</tr>
<tr>
<td></td>
<td>• CSV headers: enter, within double quotation marks, the headers used in this CSV file.</td>
</tr>
<tr>
<td></td>
<td>When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.</td>
</tr>
</tbody>
</table>

Relationship files

<table>
<thead>
<tr>
<th>Relationship files</th>
<th>Complete this table to provide the CSV files that contain the information about the relationships to be imported.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• Path to CSV file: enter, within double quotation marks, the path to the CSV file to be read.</td>
</tr>
<tr>
<td></td>
<td>• CSV headers: enter, within double quotation marks, the headers used in this CSV file.</td>
</tr>
<tr>
<td></td>
<td>When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.</td>
</tr>
</tbody>
</table>

Advanced settings

<table>
<thead>
<tr>
<th>Neo4j configuration</th>
<th>Add parameters to the table to configure the database to be created.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>For further information, see Neo4j documentation: Configuration settings.</td>
</tr>
<tr>
<td></td>
<td>When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.</td>
</tr>
</tbody>
</table>

Import configuration

| Import configuration | Add parameters to the table to configure Neo4j Import Tool.                                                                                                                                              |
For further information, see Neo4j documentation: Import Tool usage.

When entering values, use the syntax demonstrated by the examples given alongside the column names of this Nodes files table.

Global Variables

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

Usage

**Usage rule**

This component is to be used standalone in a subjob to load data in bulk from given CSV files that have been created with specific structure.

For further information about the CSV structure required by Neo4j Import Tool, see **Import**.

You can use tFileOutputDelimited to create the CSV files to be used. If so, bear the following configuration in mind:

- **Line separator**: " \n"
- **Field separator**: "," 
- Do not include headers.
- File encoding: UTF-8.

2568
tNeo4jInput

Reads data from Neo4j and sends data in the output Talend flow.

tNeo4jInput reads data from Neo4j based on Cypher query allowing any further transformation or processing of the data in the rest of the Job.

**tNeo4jInput Standard properties**

These properties are used to configure tNeo4jInput running in the Standard Job framework.

The Standard tNeo4jInput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>DB version</td>
<td>Select the Neo4j version you are using. When you are using Neo4j version 3.2.X, this component works in the remote mode only. Therefore, if you want to reuse a connection to Neo4j V3.2.X from tNeo4jConnection, ensure that you have selected the Remote server check box and properly configured the connection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels. This list is not shown if the Use an existing connection check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td>Shutdown after job</td>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component. Alternatively, you can use tNeo4jClose to shutdown the database. This avoids errors such as ‘Id file not properly shutdown’ at next execution of jobs involving Neo4j. This check box is available only if the Use an existing connection check box is not selected.</td>
</tr>
<tr>
<td>Remote server</td>
<td>Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.</td>
</tr>
<tr>
<td><strong>tNeo4jInput</strong></td>
<td></td>
</tr>
<tr>
<td>-----------------</td>
<td></td>
</tr>
</tbody>
</table>
| - **Set username**: this check box is available when you have selected the **Use a remote server** check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
- **Username** and **Password**: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.  
This check box appears only if you do not select the **Use an existing connection** check box and you are not using Neo4j V3.2.X. With V3.2.X, this component supports the remote mode only. |
| **Database path** |
| If you use Neo4j in embedded mode, specify the path of data file.  
This field appears only if you do not select the **Use an existing connection** check box or the **Remote server** check box. |
| **Schema and Edit Schema** |
| A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Query** |
| Enter your Cypher query in double quotes, with return parameters matching the mapping table. |
| **Mapping** |
| Complete this table to specify the column or columns to be extracted and the corresponding column family or families. The **Column** fields of this table are automatically filled once you have defined the schema; fill the **Return parameter** fields with return parameters to map the node properties in the Cypher query with the schema columns.  
Be sure to enclose your return parameters in double quotes. |
| **Advanced settings** |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component always needs an output link. |
| Limitation | n/a |

Related scenarios

For a related scenario, see Writing data to a Neo4j database and reading specific data from it on page 2576.
tNeo4jOutput

Receives data from the preceding component and writes the data into Neo4j.

tNeo4jOutput is used to write data into a Neo4j database, and/or update or delete entries in the database based on the index defined.

**tNeo4jOutput Standard properties**

These properties are used to configure tNeo4jOutput running in the Standard Job framework.

The Standard tNeo4jOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| DB version                 | Select the Neo4j version you are using.  
                              This component does not support Neo4j version V3.2.X.  
                              Do not reuse the connection to V3.2.X defined in a tNeo4jConnection component.  
                              Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.  
                              Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.  
                              This list is not shown if the Use an existing connection check box is selected.  
                              Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
| Remote server              | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.  
                              • Set username: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
                              • Username and Password: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.  
                              This check box appears only if you do not select the Use an existing connection check box. |
**Database path**

If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created.

This field appears only if you do not select the **Use an existing connection** check box or the **Remote server** check box.

**Shutdown after job**

Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.

Alternatively, you can use tNeo4jClose to shutdown the database.

This avoids errors such as ’Id file not properly shutdown’ at next execution of Jobs involving Neo4j.

This check box is available only if the **Use an existing connection** check box is not selected.

**Mapping**

Click the [...] button or double-click the component on the design workspace to open the indexes and relationships mapping editor. Use it to index node or create relationships during the node insertion.

- Select the **Auto indexed** check box for a column to automatically index nodes with this property.
- **Index creation**: With a column selected, click the [+ ] button to create as many indexes as you want on nodes with the property corresponding to the selected column.
  - **Name**: Specify an index name in double quotes.
  - **Key**: Specify an index key in double quotes.
  - **Value (empty for current row)**: Specify an index value in double quotes. If you leave this field empty, the default value of the index added on each node will be the value of this property of the current node.
  - **Unique**: Select this check box if you want the defined index to be created only once within the graph, rather than on each node.
- **Relationship creation**: With a column selected, click the [+ ] button to create as many relationships as you want for nodes with the property corresponding to the selected column.
  - **Type**: Specify a relationship type in double quotes.
  - **Direction**: Select a relationship direction, between **Outgoing** and **Incoming**.
  - **Index name**: Specify an index name for the relationship, in double quotes.
  - **Index key**: Specify an index key for the relationship, in double quotes.
  - **Value (empty for current row)**: Specify an index value for the relationship, in double quotes. If you leave this field empty, the default value of the index added on the relationship will be the value of this property of the current node.

**Use label (Neo4j > 2.0)**

Select this check box to create nodes with a label. Enter your label name in the **Label name** field.
This check box is not shown if **Neo4j 1.X.X** is selected from the **DB Version** list or **Delete** is selected from the **Data action** list.

Note that this option works only with Neo4j 2.0 onwards and Java 7.

### Data action

On the data of the node, you can perform:

- **Insert**: Add new node to the database.
- **Update**: Make changes to existing entries.
- **Update or insert**: Search the node with an index to update and make changes. If the node doesn’t exist, a new node will be inserted.
- **Delete**: Remove nodes fetched by the index according to the input flow.

### Index name

Specify the index name to query.

This field is available only if the action selected in **Data action** is other than **Insert**.

### Index key

Specify the index key to query.

This field is available only if the action selected in **Data action** is other than **Insert**.

### Index value

Select the index value to query.

This field is available only if the action selected in **Data action** is other than **Insert**.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word *line* when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Enter the number of rows to be completed before committing batches of nodes to the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Warning:</strong></td>
<td>This option is only supported by the embedded mode of the database. You can't make transactions in REST mode.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Batch import</th>
<th>Select this check box to activate the batch mode.</th>
</tr>
</thead>
</table>
| **Warning:** | - This option is only supported by the embedded mode of the database.  
  - It is recommended that you perform a backup operation before executing the Job to prevent data corruption. |

<table>
<thead>
<tr>

</tbody>
</table>

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
  **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
|------------------|----------------------------------------------------------------------------------------------------------------------------------|

2575
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component and it always needs an incoming link.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### Writing data to a Neo4j database and reading specific data from it

This scenario applies only to Talend products with Big Data.

This basic scenario describes a Job composed of two subJobs: the first subJob reads employees data from a CSV file and writes it to a Neo4j database, and then triggers the second subJob, which reads the employees data based on certain query conditions from the Neo4j database and displays the data on the Run console.

### Adding and linking components

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a tFileInputDelimited component, to read the employees data from a CSV file,
   - a tNeo4jOutput component to write the employees data to a Neo4j database,
   - a tNeo4jInput component to read the employees data from the Neo4j database based on given conditions, and
   - a tLogRow component to display the data on the Run console.
2. Link the tFileInputDelimited component to the tNeo4jOutput component using a Row > Main connection.
3. Link the tNeo4jInput component to the tLogRow component using a Row > Main connection.
4. Link the tFileInputDelimited component to the tNeo4jInput component using a Trigger > On Subjob Ok connection.
5. Label the components to better identify their roles in the Job.
Configuring the components

Importing data to the Neo4j database

Procedure

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the Components tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the employees data to read.

   The input CSV file used in this example is as follows:

   ```
   employeeID;employeeName;age;hireDate;salary;managerID
   1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
   2;Warren Adams;43;05-22-2008;11626.68;m6
   3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
   4;Herbert Quincy;54;06-14-2007;10694.71;m6
   5;Woodrow Polk;33;08-14-2007;13751.50;m4
   6;Theodore Johnson;47;01-26-2008;12426.87;m6
   7;Benjamin Adams;32;02-25-2008;10438.65;m4
   8;Woodrow Harrison;51;10-11-2008;11188.27;m5
   9;George Truman;40;04-28-2008;14254.49;m5
   10;Harry Jackson;38;04-01-2008;12798.78;m6
   ```
3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: `employeeID` (integer), `employeeName` (String), `age` (Integer), `hireDate` (Date), `salary` (Float), and `managerID` (String).

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

5. Click the **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

   Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, “http://localhost:7474/db/data” in this example.

6. If needed, click the **Sync columns** button to ensure the component has the same schema as the preceding component.

   Keep the rest of the parameters as they are.
Reading data from the Neo4j database

Procedure

1. Double-click the `tNeo4jInput` component to open its **Basic settings** view.

![Neo4jInput Component](Image)

2. As in the `tNeo4jOutput` component, specify the URL of the Neo4j server to connect to, "http://localhost:7474/db/data" in this example.

3. Click the [...] button next to **Edit schema** and define the schema for employees information display. When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

![Schema Dialog Box](Image)

The defined schema columns automatically appear in the **Mapping** table.
4. In the **Query** field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find employees who are more than 40 years old and are under the manager m6.

```cypher
"MATCH (n) WHERE n.age > 40 AND n.managerID = 'm6' RETURN n;"
```

5. Fill the **Return parameter** field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the **tLogRow** component to open its **Basic settings** view, and select the **Table (print values in cells of a table)** option to display the retrieved information in a table.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

The employees data of the CSV file is written to the Neo4j database and then the information of employees matching the set conditions is retrieved from the Neo4j database and displayed on the console.

### Writing family information to Neo4j and creating relationships

This scenario applies only to **Talend products with Big Data**.

This scenario describes a Job that will write family information to labeled nodes in a remote Neo4j database and create relationships based on the family names.

#### Adding and linking components

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
   - a **tFileInputDelimited** component, to read the family data from a CSV file,
• a **tNeo4jOutput** component to write the family data to a Neo4j database and create relationships between husband and wife.

2. Link the **tFileInputDelimited** component to the **tNeo4jOutput** component using a **Row > Main** connection.

3. Label the components to better identify their roles in the Job.

### Configuring the components

#### Configuring the data source

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the Components tab.

![Basic settings](image)

2. In the **File name/Stream** field, specify the path to the CSV file that contains the family data to read.

   The input CSV file used in this example is as follows:

   ```
   Name;Gender;Age;Family
   Jenny;Female;24;the Johnsons
   Jack;Male;26;the Johnsons
   Richard;Male;35;the Blacks
   Anne;Female;36;the Whites
   Helen;Female;28;the Blacks
   Tom;Male;38;the Whites
   ```

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: *name* (integer), *gender* (String), *age* (Integer), and *family* (String).
When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

![Schema of Families](image)

**Writing data to Neo4j and creating indexes and relationships**

**Procedure**

1. Click the **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

2. From the **DB Version** list, select **Neo4j 2.X.X** to enable node labeling.
3. Define a Neo4j database connection. In this example, the Neo4j database is accessible in REST mode, so select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.
4. Double-click the `tNeo4jOutput` component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

5. With the `name` column selected from the schema panel, click the **Index creation** tab, click the `[+]` button to add a row in the table, and create an index named `first_name` on this column:
   - In the **Name** field, enter `first_name` between double quotation marks.
   - In the **Key** field, enter `first_name` between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation.

6. With the `family` column selected from the schema panel, click the **Index creation** tab, click the `[+]` button to add a row in the table, and create an index named `family` on this column:
   - In the **Name** field, enter `family` between double quotation marks.
   - In the **Key** field, enter `family_name` between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation.

7. With the `family` column selected from the schema panel, click the **Relationship creation** tab, click the `[+]` button to add a row in the table, and create a relationship named `Spouse` on this column based on the index named `family`:
   - In the **Type** field, enter `Spouse` between double quotation marks.
   - From the **Direction** list field, select either **Outgoing** or **Incoming**.
   - In the **Index Name** field, enter `family` between double quotation marks.
   - In the **Index Key** field, enter `family_name` between double quotation marks.

Then click in the schema panel to validate your relationship creation, and click **OK** to close the mapping editor.
8. Select the **Use label (Neo4j > 2.0)** check box and enter *Families* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Families*.

9. From the **Data action** list, select **Insert or update**, and set a reference key in the **Index** area that appears:

   - In **Index name** field, enter *first_name* between double quotation marks.
   - In **Index key** field, enter *first_name* between double quotation marks.
   - From **Index value** field, select *name*. As the **Value** field is left blank in index creation, the index value will be the value of the *name* column for each row.

   This way, when the Job is executed, nodes will be inserted or updated in the Neo4j database based on the **first_name** index: for each data row, if a node containing the same first name already exists in the database, the node will be updated; otherwise, a new node will be created.

**Executing the Job and checking the result**

**Procedure**

1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.
2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, `http://localhost:7474/` in this example, and enter the following Cypher query in the command line to view the nodes.

   ```cypher
   MATCH (n:`Families`) RETURN n;
   ```

As shown in the graphic view, three pairs of nodes labeled *Families* have been created and those with the same family name are linked together via the relationship *Spouse*. 
MATCH (n: Families) RETURN n;

Families [6]

Properties

- name: Jenny
- gender: Female
- age: 24
- family: The Johnsons

Displaying 6 nodes, 6 relationships
tNeo4jOutputRelationship

Receives data from the preceding component and writes relationships into Neo4j.

**tNeo4jOutputRelationship Standard properties**

These properties are used to configure tNeo4jOutputRelationship running in the Standard Job framework.

The Standard tNeo4jOutputRelationship component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
| DB version              | Select the Neo4j version you are using.  
This component does not support Neo4j version V3.2.X.  
Do not reuse the connection to V3.2.X defined in a tNeo4jConnection component.  
Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur.  
Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels.  
This list is not shown if the Use an existing connection check box is selected.  
Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |
| Remote server           | Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field.  
• Set username: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear.  
• Username and Password: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.  
This check box appears only if you do not select the Use an existing connection check box. |
| Database path           | If you use Neo4j in embedded mode, specify the path of data file. |
This field appears only if you do not select the Use an existing connection check box.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

**Server url**

If you use Neo4j in REST mode, specify the root URL. This field appears only if you select the Remote server check box.

**Shutdown after job**

Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.

Alternatively, you can use tNeo4jClose to shutdown the database.

This avoids errors such as ‘Id file not properly shutdown’ at next execution of Jobs involving Neo4j.

This check box is available only if the Use an existing connection check box is not selected.

**Relationship type**

Specify the relationship type to create for each row.

**Start node / Index name**

Specify the index name to query the starting node of the newest relationship.

**Start node / Index key**

Specify the index key to query the starting node.
Start node / Index value
Select the index value to query the starting node.

Relationship direction
Select a relationship direction.
• **Outgoing**: The relationship starts from the start node to the end node.
• **Incoming**: The relationship starts from the end node to the start node.

End node / Index name
Specify the index name to query the ending node of the newest relationship.

End node / Index key
Specify the index key to query the ending node.

End node / Index value
Select the index value to query the ending node.

Mapping
Use this table to map relationship properties with the input schema columns.

**Advanced settings**

Commit every
Enter the number of rows to be completed before committing batches of nodes together the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

This option is only supported by the embedded mode of the database. You can’t make transactions in REST mode.

Batch import
Select this check to activate the batch mode.

This option is only supported by the embedded mode of the database. **Be very careful with the batch import mode. Because this option is unsafe, perform a backup before Job execution.**

If you want more explanations about memory mapping configuration of batch import, please refer to Neo4j documentation at: [http://neo4j.com/docs/stable/batchinsert-examples.html](http://neo4j.com/docs/stable/batchinsert-examples.html)

Node store mapped memory
Type in the memory size in MB allocated to nodes.

Relationship store mapped memory
Type in the memory size in MB allocated to relationships.

Property store mapped memory
Type in the memory size in MB allocated to property.

String store mapped memory
Type in the memory size in MB in Mo allocated to strings.

Array store mapped memory
Type in the memory size in MB allocated to arrays.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**
**NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an output component and it always needs an incoming link.</th>

**Writing information of actors and movies to Neo4j with hierarchical relationship**

This scenario applies only to **Talend products with Big Data**.

This scenario describes a Job that will import information about actors and movies from two CSV files into a remote Neo4j database and then create relationship between the actors and the movies based on another CSV file that describes the actors’ roles in the movies.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
   - a **tNeo4jConnection** component, to open a connection to a Neo4j database,
   - three **tFileInputDelimited** components, to read the input information of actors and movies,
   - two **tNeo4jOutput** components, to write information of movies and actors to the connected Neo4j database,
   - a **tNeo4jOutputRelationship** component, to create relationship between actors and movies, and
   - a **tNeo4jClose** component, to close the previous opened Neo4j connection at the end of Job execution.

2. Link the first **tFileInputDelimited** to the first **tNeo4jOutput** component using a **Row > Main** connection. This subJob will import the actors data into the Neo4j database.

3. Link the second **tFileInputDelimited** component to the second **tNeo4jOutput** component using a **Row > Main** connection. This subJob will import the movies data into the Neo4j database.

4. Link the third **tFileInputDelimited** component to the **tNeo4jOutputRelationship** component using a **Row > Main** connection. This subJob will create relationship between actors and movies.
5. Link the subjobs using **Trigger > On Subjob Ok** connections.
6. Label the components to better identify their roles in the Job.

**Configuring the components**

**Opening a Neo4j database connection**

**Procedure**

1. Double-click the **tNeo4jConnection** component to open its **Basic settings** view on the **Component** tab.
2. From the **DB Version** list, select **Neo4J 2.X.X** to enable node labeling.
3. Select the **Use a remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.

**Importing the actors data into Neo4j**

**Procedure**

1. Double-click the first **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that describes the actors’ names, the years they were born in, and their roles in the movies. The input CSV file used in this example is as follows:

<table>
<thead>
<tr>
<th>Name</th>
<th>Born</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keanu Reeves</td>
<td>1964</td>
</tr>
<tr>
<td>Laurence Fishburne</td>
<td>1961</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>1967</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of two columns, **name** and **born**, both of type String.

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
5. Click the first `tNeo4jOutput` component and select the **Component** tab to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the `tNeo4jConnection` component, which is the only connection component used in this example.

7. Double-click the `tNeo4jOutput` component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

8. With the `name` column selected from the schema panel, click the **Index creation** tab, click the `[+]` button to add a row in the table, and create an index named `name` on this column:
   - In the **Name** field, enter `name` between double quotation marks.
   - In the **Key** field, enter `name` between double quotation marks to give the index a key `name`.

Then click in the schema panel to validate your index creation, and click **OK** to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Actors* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Actors*.

**Importing the movies data into Neo4j**

**Procedure**

1. Double-click the second **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the information of the movies.
The input CSV file used in this example is as follows:

<table>
<thead>
<tr>
<th>Title</th>
<th>Released</th>
<th>Tagline</th>
</tr>
</thead>
<tbody>
<tr>
<td>The Matrix</td>
<td>03-31-1999</td>
<td>Welcome to the Real World</td>
</tr>
<tr>
<td>The Matrix Reloaded</td>
<td>05-07-2003</td>
<td>Free Your Mind</td>
</tr>
<tr>
<td>The Matrix Revolutions</td>
<td>10-27-2003</td>
<td>Everything that has a Beginning has an End</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, **title** (type String), **released** (type Date), and **tagline** (type String).

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

5. Click the second **tNeo4jOutput** component and select the **Component** tab to open its **Basic settings** view.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. Double-click the **tNeo4jOutput** component or click the **Mapping** button on the component’s **Basic settings** view to open the index and relationship mapping editor.

8. With the **title** column selected from the schema panel, click the **Index creation** tab, click the [+ ] button to add a row in the table, and create an index named **title** on this column:

   • In the **Name** field, enter **title** between double quotation marks.
   • In the **Key** field, enter **title** between double quotation marks to give the index a key.

Then click in the schema panel to validate your index creation, and click **OK** to close the mapping editor.
9. Select the **Use label (Neo4j > 2.0)** check box and enter *Movies* between double quotation marks in the **Label name** field so that the nodes to be created will be labeled *Movies*.

**Creating actor-movie relationship in Neo4j**

**Procedure**

1. Double-click the third **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that describes the actors’ roles in the movies.
The input CSV file used in this example is as follows:

<table>
<thead>
<tr>
<th>Actor</th>
<th>Movie</th>
<th>Role</th>
</tr>
</thead>
<tbody>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix</td>
<td>Neo</td>
</tr>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix Reloaded</td>
<td>Neo</td>
</tr>
<tr>
<td>Keanu Reeves</td>
<td>The Matrix Revolutions</td>
<td>Neo</td>
</tr>
<tr>
<td>Laurence Fishburn</td>
<td>The Matrix</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Laurence Fishburn</td>
<td>The Matrix Reloaded</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Laurence Fishburn</td>
<td>The Matrix Revolutions</td>
<td>Morpheus</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix</td>
<td>Trinity</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix Reloaded</td>
<td>Trinity</td>
</tr>
<tr>
<td>Carrie-Anne Moss</td>
<td>The Matrix Revolutions</td>
<td>Trinity</td>
</tr>
</tbody>
</table>

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of three columns, **actor**, **movie**, and **role**, all of type String.

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

5. Double-click the **tNeo4jOutputRelationship** component to open its **Basic settings** view.

   ![Image of tNeo4jOutputRelationship component](image)

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Relationship type** field, enter the type of relationship to be created, between double quotation marks. In this example, the relationship type is **ACTED_IN**, which will appear as the label of the relationship between nodes.

8. Define the start and end nodes and the direction of the relationship to be created. In this example, the relationship will be created from **Actors** nodes, on which an index called **name** has been defined, to **Movies** nodes, on which an index called **title** has been defined.
• **Start node**: enter *name* between double quotation marks in the **Index name** and **Index key** fields, and select the schema column *name* from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column *name* for each row.

• From the **Relationship direction** list, select **Outgoing**.

• **End node**: enter *title* between double quotation marks in the **Index name** and **Index key** fields, and select the schema column *title* from the **Index value** list. As the **Value** field is left blank in index creation, the index value will be the value of column *title* for each row.

9. Click the [+ ] button three times to add three rows in the **Mapping** table to define three properties of the relationship:

<table>
<thead>
<tr>
<th>Property</th>
<th>Value taken from...</th>
</tr>
</thead>
<tbody>
<tr>
<td><em>Actor</em></td>
<td><em>actor</em> column of the schema</td>
</tr>
<tr>
<td><em>Movie</em></td>
<td><em>movie</em> column of the schema</td>
</tr>
<tr>
<td><em>Role</em></td>
<td><em>role</em> column of the schema</td>
</tr>
</tbody>
</table>

**Executing the Job and checking the result**

**Procedure**

1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.

2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, `http://localhost:7474/` in this example, and enter the following Cypher query in the command line to view the nodes with the specified relationship between them.

```cypher
MATCH (a)-[:`ACTED_IN`]->(b) RETURN a,b;
```

As shown in the graphic view, *Actors* nodes are linked with *Movies* nodes via the relationship *ACTED_IN*, with properties as defined in the Job.
MATCH (a) - [:ACTED_IN] -> (b) RETURN a, b;

- **Movies**
  - The Matrix
  - The Matrix Revolutions
  - The Matrix

- **Actors**
  - Laurence Fishburne
  - Keanu Reeves
  - Hugo Weaving

**Displaying 6 nodes, 9 relationships**
**tNeo4jRow**

Executes the stated Cypher query onto the specified Neo4j database.

Depending on the nature of the query, tNeo4jRow acts on the data (although without handling data). tNeo4jRow is the specific component for Neo4j database query. It implements a flow in the Job design although it doesn’t provide output.

**tNeo4jRow Standard properties**

These properties are used to configure tNeo4jRow running in the Standard Job framework.

The Standard tNeo4jRow component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>DB version</strong></td>
<td>Select the Neo4j version you are using. When you are using Neo4j version 3.2.X, this component works in the remote mode only. Therefore, if you want to reuse a connection to Neo4j V3.2.X from tNeo4jConnection, ensure that you have selected the Remote server check box and properly configured the connection. Do not use a 2.X.X version and a 3.X.X version in the same Job. Otherwise, class conflict issues occur. Neo4j version 2.X.X is compatible only with Java 7 or higher but it offers support of advanced features such as node labels. This list is not shown if the Use an existing connection check box is selected. Upon selecting a database version, you will be prompted to install the corresponding database driver JAR files if not yet installed. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
<tr>
<td><strong>Remote server</strong></td>
<td>Select this check box if you use a Neo4j remote server, and specify the root URL in the Server URL field. • <strong>Set username</strong>: this check box is available when you have selected the Use a remote server check box and the Neo4j version you are using is earlier than 2.2. If the remote Neo4j server you want to connect to does not require user credentials, leave it clear. • <strong>Username</strong> and <strong>Password</strong>: enter the authentication information to connect to the remote Neo4j server to be used. Since Neo4j 2.2, user credentials are always required.</td>
</tr>
<tr>
<td><strong>This check box appears only if you do not select the Use an existing connection check box and you are not using Neo4j V3.2.X. With V3.2.X, this component supports the remote mode only.</strong></td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
<tr>
<td><strong>Database path</strong></td>
<td></td>
</tr>
<tr>
<td>If you use Neo4j in embedded mode, specify the directory to hold your data files. If the specified directory does not exist, it will be created.</td>
<td></td>
</tr>
<tr>
<td>This field appears only if you do not select the Use an existing connection check box or the Remote server check box.</td>
<td></td>
</tr>
<tr>
<td><strong>Shutdown after job</strong></td>
<td></td>
</tr>
<tr>
<td>Select this check box to shutdown the Neo4j database connection when no more operations on Neo4j are going to be performed after the current component.</td>
<td></td>
</tr>
<tr>
<td>Alternatively, you can use tNeo4jClose to shutdown the database.</td>
<td></td>
</tr>
<tr>
<td>This avoids errors such as 'Id file not properly shutdown’ at next execution of Jobs involving Neo4j.</td>
<td></td>
</tr>
<tr>
<td>This check box is available only if the Use an existing connection check box is not selected.</td>
<td></td>
</tr>
<tr>
<td><strong>Schema and Edit schema</strong></td>
<td></td>
</tr>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
<td></td>
</tr>
<tr>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
<td></td>
</tr>
<tr>
<td>• View schema: choose this option to view the schema only.</td>
<td></td>
</tr>
<tr>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
<td></td>
</tr>
<tr>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
<tr>
<td>When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.</td>
<td></td>
</tr>
<tr>
<td>You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
<td></td>
</tr>
<tr>
<td><strong>Query</strong></td>
<td></td>
</tr>
</tbody>
</table>
| Enter your Cypher query in double quotes. If you have some parameters corresponding to the input schema columns,
declare them with curly brackets ({})) and map them in the Parameters table.

### Parameters
Click the [+] button to add parameters corresponding to your Cypher query and map them with the input schema columns.

- **Parameter name**: Type in the name of your parameter, in double quotes.
- **Parameter value**: Select the schema column you want to map your parameter with.

### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to gather the Job processing metadata at the Job level as well as at each component level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Commit every</td>
<td>Enter the number of rows to be completed before committing batches of nodes together the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution. This option is only supported by the embedded mode of the database. You cannot make transactions in REST mode, that is to say, not on a remote server in the deprecated 2.X.X versions.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_NODE_INSERTED: the number of nodes inserted. This is an After variable and it returns a long.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_RELATIONSHIP_INSERTED: the number of relationships inserted. This is an After variable and it returns a long.</td>
</tr>
<tr>
<td></td>
<td>NB_PROPERTY_UPDATED: the number of properties updated. This is an After variable and it returns a long.</td>
</tr>
<tr>
<td></td>
<td>NB_NODE_DELETED: the number of nodes deleted. This is an After variable and it returns a long.</td>
</tr>
<tr>
<td></td>
<td>NB_RELATIONSHIP_DELETED: the number of relationships deleted. This is an After variable and it returns a long.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used as a standalone component or as an output component in a process.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>n/a</td>
</tr>
</tbody>
</table>

### Creating nodes with a label using a Cypher query

This scenario applies only to **Talend products with Big Data**.

This scenario describes a Job that creates nodes with a label in an embedded Neo4j database using a Cypher query, and then displays some properties of the specified node on the console.

### Adding and linking components

#### Procedure

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the **Palette**:
   - a **tNeo4jConnection** component, to open a connection to a Neo4j database,
   - a **tNeo4jRow** component, to create nodes in the Neo4j database with a Cypher query,
   - a **tNeo4jIntput** component, to read the specified properties of the created nodes,
   - a **tLogRow** component, to display the data on the **Run** console, and
   - a **tNeo4jClose** component, to close the Neo4j database connection established by the **tNeo4jConnection** component.

2. Link the **tNeo4jConnection** component to the **tNeo4jRow** component using a **Trigger > On Subjob Ok** connection.

3. Link the **tNeo4jRow** component to the **tNeo4jIntput** component using a **Trigger > On Subjob Ok** connection.

4. Link the **tNeo4jIntput** component to the **tLogRow** component using a **Row > Main** connection.

5. Link the **tNeo4jIntput** component to the **tNeo4jClose** component using a **Trigger > On Subjob Ok** connection.
Configuring the components

Configuring a Neo4j database connection and nodes creation

Procedure

1. Double-click the `tNeo4jConnection` component to open its Basic settings view on the Component tab.

2. From the DB Version list, select `Neo4J 2.X.X` to enable node labeling support.

3. In the Database path field, specify the directory for your data files, "E:/Talend/DB/Neo4j/data" in this example.

In this example, you will use Neo4j in embedded mode; to connect to a remote Neo4j server via REST, click the Use a remote server check box and specify the URL of the Neo4j server.
4. Double-click the `tNeo4jRow` component to open its **Basic settings** view on the **Component** tab.

![tNeo4jRow component](image)

5. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the `tNeo4jConnection` component, which is the only connection component used in this example.

6. In the **Query** field, type in the Cypher query to be executed by the component. In this example, type in the following query to create two nodes with the label `Managers` and three properties - `id`, `name`, and `position`:

```
CREATE (a:Managers { id: 1, name: 'Gerald White', position: 'HR directory'})
CREATE (b:Managers { id: 2, name: 'Jimmy Black', position: 'Sales manager'})
```

As this component does not have an input flow, leave the schema and the parameter settings blank.

**Configuring data retrieving and display**

**Procedure**

1. Double-click the `tNeo4jInput` component to open its **Basic settings** view.

![tNeo4jInput component](image)

2. Select the **Use an existing connection** check box to reuse the connection opened by the `tNeo4jConnection` component.
3. Click the [...] button next to **Edit schema** and define the schema corresponding to the node properties you want to retrieve and display. In this example, the schema is composed of two columns, *name* and *position*, both of type String.

When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.

![Schema of tNeo4jInput_1](image)

The defined schema columns automatically appear in the **Mapping** table.

4. In the **Query** field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to find the name and position of the manager whose ID is 2.

```cypher
"MATCH (ee:Managers{id:2}) RETURN ee.name, ee.position;"
```

or

```cypher
"MATCH (ee:Managers) WHERE ee.id = 2 RETURN ee.name, ee.position;"
```

5. Fill the **Return parameter** field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the **tLogRow** component to open its **Basic settings** view, and select the **Table (print values in cells of a table)** option to display the retrieved information in a table.

### Executing the Job

**Procedure**

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

```
[statistics] connecting to socket on port 4076
[statistics] connected
<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
</table>
name | position |
| Jimmy Black | Sales manager |
```

```
[statistics] disconnected
```

2605
Two nodes are created in the Neo4j database based on the Cypher query, with the data files written in the specified directory, and the defined information is retrieved and displayed on the console.

**Importing data from a CSV file to Neo4j using a Cypher query**

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that first imports employees data from a CSV file into a Neo4j database using a Cypher query, and then displays the information on the console.

**Adding and linking components**

**Procedure**

1. Create a Job and add the following components to the Job by typing theirs names in the design workspace or dropping them from the Palette:
   - a `tNeo4jConnection` component, to open a connection to a Neo4j database,
   - a `tFileInputDelimited` component, to read the source data from a CSV file,
   - a `tNeo4jRow` component, to write the employees data to the Neo4j database with a Cypher query,
   - a `tNeo4jInput` component, to read the employees data from the Neo4j database,
   - a `tLogRow` component, to display the data on the Run console, and
   - a `tNeo4jClose` component, to close the Neo4j database connection opened by the `tNeo4jConnection` component.

2. Link the `tNeo4jConnection` component to the `tFileInputDelimited` component using a `Trigger > On Subjob Ok` connection.

3. Link the `tFileInputDelimited` component to the `tNeo4jRow` component using a `Row > Main` connection.

4. Link the `tFileInputDelimited` component to the `tNeo4jInput` component using a `Trigger > On Subjob Ok` connection.

5. Link the `tNeo4jInput` component to the `tLogRow` component using a `Row > Main` connection.

6. Link the `tNeo4jInput` component to the `tNeo4jClose` component using a `Trigger > On Subjob Ok` connection.

7. Label the components to better identify their roles in the Job.
Configuring the components

Configuring a Neo4j database connection

Procedure

1. Double-click the tNeo4jConnection component to open its Basic settings view on the Component tab.

2. From the DB Version list, select Neo4J 2.X.X.

3. Select the Use a remote server check box and specify the URL of the Neo4j server in the Server URL field, "http://localhost:7474/db/data" in this example.
In this example, you will use Neo4j in REST mode; to connect to a remote Neo4j server in embedded mode, clear the **Use a remote server** check box and specify the Neo4j data file directory in the **Database path** field.

**Configuring data import**

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view on the **Component** tab.

2. In the **File name/Stream** field, specify the path to the CSV file that contains the employees data to read. The input CSV file used in this example is as follows:

   ```
   employeeID;employeeName;age;hireDate;salary;managerID
   1;Rutherford Roosevelt;38;06-10-2008;13336.58;m5
   2;Warren Adams;43;05-22-2008;11626.68;m6
   3;Andrew Roosevelt;55;04-01-2007;10052.95;m4
   4;Herbert Quincy;54;06-14-2007;10694.71;m6
   5;Woodrow Polk;33;08-14-2007;13751.50;m4
   6;Theodore Johnson;47;01-26-2008;12426.87;m6
   7;Benjamin Adams;32;02-25-2008;10438.65;m4
   8;Woodrow Harrison;51;10-11-2008;11188.27;m5
   9;George Truman;40;04-28-2008;14254.49;m5
   10;Harry Jackson;38;04-01-2008;12798.78;m6
   ```

3. In the **Header** field, specify the number of rows to skip as header rows. In this example, the first row of the CSV file is the header row.

4. Click the [...] button next to **Edit schema** to open the **Schema** dialog box, and define the input schema based on the structure of the input file. In this example, the input schema is composed of six columns: **employeeID** (integer), **employeeName** (String), **age** (Integer), **hireDate** (Date), **salary** (Double), and **managerID** (String). When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
5. Double-click the **tNeo4jRow** component to open its **Basic settings** view on the **Component** tab.

6. Select the **Use an existing connection** check box to reuse the Neo4j database connection opened by the **tNeo4jConnection** component, which is the only connection component used in this example.

7. In the **Query** field, type in the Cypher query to be executed by the component.

   In this example, type in the following query to create nodes with the label **Employees** and six properties, to hold the data from the input flow:

   - **ID**, which will take the value of the variable parameter **id**,
   - **Name**, which will take the value of the variable parameter **name**,
   - **Age**, which will take the value of the variable parameter **age**,
- *HireDate*, which will be the value of the variable parameter *hire_date*,
- *Salary*, which will take the value of the variable parameter *salary*, and
- *ManagerID*, which will be the value of the variable parameter *manager_id*.

```
CREATE (n:Employees{ID:{id}, Name:{name}, Age:{age}, HireDate:{hire_date}, Salary:{salary}, ManagerID:{manager_id}})
```

8. In the **Parameters** table, type in the variable parameters in the **Parameter** field in accordance with your Cypher query, and map each of them with an input schema column by selecting it from the **Parameter value** list field.

<table>
<thead>
<tr>
<th>Parameter name</th>
<th>Parameter value</th>
</tr>
</thead>
<tbody>
<tr>
<td>&quot;id&quot;</td>
<td>employeeID</td>
</tr>
<tr>
<td>&quot;name&quot;</td>
<td>employeeName</td>
</tr>
<tr>
<td>&quot;age&quot;</td>
<td>age</td>
</tr>
<tr>
<td>&quot;hire_date&quot;</td>
<td>hireDate</td>
</tr>
<tr>
<td>&quot;salary&quot;</td>
<td>salary</td>
</tr>
<tr>
<td>&quot;manager_id&quot;</td>
<td>managerID</td>
</tr>
</tbody>
</table>

**Configuring data retrieving and display**

**Procedure**

1. Double-click the **tNeo4jInput** component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box to reuse the connection opened by the **tNeo4jConnection** component.

3. Click the [...] button next to **Edit schema** and define the schema corresponding to the node properties you want to retrieve and display.

   When done, click **OK** to close the **Schema** dialog box and propagate the schema to the next component.
The defined schema columns automatically appear in the Mapping table.

4. In the Query field, type in the Cypher query to match the data to read from the Neo4j database. In this example, use the following Cypher query to retrieve all the properties of all the nodes with the label Employees.

```
"MATCH (n:Employees) RETURN *;
```

5. Fill the Return parameter field for each schema column with a return parameter in double quotes to map the node properties in the Neo4j database with the schema columns.

6. Double-click the tLogRow component to open its Basic settings view, and select the Table (print values in cells of a table) option to display the retrieved information in a table.

**Executing the Job**

**Procedure**

1. Press Ctrl+S to save the Job.
2. Press F6 or click Run on the Run tab to run the Job.
The employees data in the CSV file is written to the Neo4j database and displayed on the console.

### Importing data from a CSV file to Neo4j and creating relationships using a single Cypher query

This scenario applies only to Talend products with Big Data.

This scenario describes a Job that imports family information from a CSV file into a remote Neo4j database and create relationships between persons and families using a single Cypher query through a **tNeo4jRow** component.

Below is content of the CSV file to import data from in this example:

<table>
<thead>
<tr>
<th>Name</th>
<th>Gender</th>
<th>Age</th>
<th>Family</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jenny</td>
<td>Female</td>
<td>24</td>
<td>the Johnsons</td>
</tr>
<tr>
<td>Jack</td>
<td>Male</td>
<td>26</td>
<td>the Johnsons</td>
</tr>
<tr>
<td>Richard</td>
<td>Male</td>
<td>35</td>
<td>the Blacks</td>
</tr>
<tr>
<td>Anne</td>
<td>Female</td>
<td>36</td>
<td>the Whites</td>
</tr>
<tr>
<td>Helen</td>
<td>Female</td>
<td>28</td>
<td>the Blacks</td>
</tr>
<tr>
<td>Tom</td>
<td>Male</td>
<td>38</td>
<td>the Whites</td>
</tr>
</tbody>
</table>

As **MERGE** is used with **LOAD CSV** in this example, to ensure the Cypher query is executed in an efficient way, another **tNeo4jRow** component is used to create an index on the property to merge.

### Adding and linking components

#### Procedure

1. Create a Job and add two **tNeo4jRow** components to the Job by typing the component name in the design workspace or dropping them from the **Palette**.
2. Link the components using a **Trigger > On Sub Job Ok** connection.
3. Label the components to better identify their roles in the Job.
Configuring the components

Creating an index

Procedure

1. Double-click the first tNeo4jRow component to open its Basic settings view on the Component tab.

2. From the DB Version list, select Neo4J 2.X.X.

3. Select the Remote server check box and specify the URL of the Neo4j server in the Server URL field, "http://localhost:7474/db/data" in this example.

4. In the Query field, type in the following query to create an index on the property you are going to merge, which is the name property of the Family nodes in this example:

   "CREATE INDEX ON :Family(name)"

Importing data and creating relationships

Procedure

1. Double-click the second tNeo4jRow component to open its Basic settings view on the Component tab.
2. From the **DB Version** list, select **Neo4j 2.X.X**.

3. Select the **Remote server** check box and specify the URL of the Neo4j server in the **Server URL** field, "http://localhost:7474/db/data" in this example.

4. In the **Query** field, type in the following Cypher query to import family data from the CSV file, create relevant **Person** and **Family** nodes, and create relationships between persons and families:

   "LOAD CSV WITH HEADERS FROM 'file:E:/Talend/Data/Input/families.csv' AS csvLine
   FIELDTERMINATOR ';'
   MERGE (family:Family { name: csvLine.Family })
   CREATE (person:Person { name: csvLine.Name, gender: csvLine.Gender, age: toInt(csvLine.Age)})
   CREATE (person)-[:From]->(family)"

**Executing the Job and checking the result**

**Procedure**

1. Press **Ctrl+S** to save the Job, and press **F6** or click **Run** on the **Run** tab to run the Job.

2. In the address bar of your Web browser, enter the URL of the Neo4j database browser, http://localhost:7474/ in this example, and enter the following Cypher query in the command line to view the **Person** and **Family** nodes linked via the relationship **From**:

   ```cypher
   MATCH (a:Person)-[:From]->(b:Family) RETURN a,b;
   ```

As shown in the graphic view, nodes labeled **Family** and **Person** have been created and the nodes of persons from the same families are linked with the relevant **Family** nodes via the relationship **From**.
MATCH (a:Person)-[:From]->(b:Family) RETURN a, b;
tNetezzaBulkExec

Offers gains in performance while carrying out the Insert operations to a Netezza database.

**tNetezzaBulkExec Standard properties**

These properties are used to configure tNetezzaBulkExec running in the Standard Job framework.

The Standard tNetezzaBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>

</tbody>
</table>

---

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th><strong>Table</strong></th>
<th>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</th>
</tr>
</thead>
</table>
| **Schema and Edit Schema** | **Built-In**: You create and store the schema locally for this component only. **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. **Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:**  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **File Name** | Name of the file to be loaded. This file should be located on the same machine where the Studio is installed or where the Job using **tNetezzaBulkExec** is deployed. |

### Advanced settings

<p>| <strong>Additional JDBC Parameters</strong> | Specify additional JDBC parameters for the database connection created. This property is not available when the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong> view is selected. |
| <strong>Field Separator</strong> | Character, string or regular expression to separate fields. |
| <strong>Escape character</strong> | Character of the row to be escaped. |
| <strong>Date format / Date delimiter</strong> | Use Date format to distinguish the way years, months and days are represented in a string. Use Date delimiter to specify the separator between date values. |</p>
<table>
<thead>
<tr>
<th><strong>Time format/ Time delimiter</strong></th>
<th>Use Time format to distinguish the time is represented in a string. Use Time delimiter to specify the separator between time values.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually. This field is compulsory for DB data handling.</td>

<td>For further information about variables, see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component is mainly used when non particular transformation is required on the data to be loaded on to the database.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic](#).
connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation                                                                 | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

For use cases in relation with **tNetezzaBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tNetezzaClose

Closes the transaction committed in the connected Netezza database.

**tNetezzaClose Standard properties**

These properties are used to configure tNetezzaClose running in the Standard Job framework.

The Standard tNetezzaClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

**Usage**

**Usage rule**

This component is to be used along with Netezza components, especially with tNetezzaConnection and tNetezzaCommit.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenarios

No scenario is available for the Standard version of this component yet.
tNetezzaCommit

 Validates the data processed through the Job into the connected Netezza database.

 Using a unique connection, tNetezzaCommit commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

### tNetezzaCommit Standard properties

These properties are used to configure tNetezzaCommit running in the Standard Job framework.

The Standard tNetezzaCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

#### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

_**Warning:** If you want to use a Row > Main connection to link tNetezzaCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit._

#### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

#### Usage

| Usage rule | This component is more commonly used with other tNetezza* components, especially with the tNetezzaConnection and tNetezzaRollback components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces |
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tNetezzaCommit related scenario, see Inserting data in mother/daughter tables on page 2426.
tNetezzaConnection

Opens a connection to a Netezza database to be reused in the subsequent subJob or subJobs.

### tNetezzaConnection Standard properties

These properties are used to configure tNetezzaConnection running in the Standard Job framework.

The Standard tNetezzaConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional connection properties for the DB connection you are creating.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the Shared DB Connection Name field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the Use dynamic job and Use an independent process to run subjob options of the tRunJob component. Using a shared connection together</td>
</tr>
</tbody>
</table>
with a `tRunJob` component with either of these two options enabled will cause your Job to fail.

### Advanced settings

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

### Usage

<p>| | |</p>
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Usage rule</strong></td>
<td>This component is more commonly used with other tNetezza* components, especially with the <code>tNetezzaCommit</code> and <code>tNetezzaRollback</code> components.</td>
</tr>
<tr>
<td><strong>Limitation</strong></td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the <code>Install</code> button on the <code>Component</code> tab view. You can also find out and add all missing JARs easily on the <code>Modules</code> tab in the <code>Integration</code> perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Related scenarios

For a `tNetezzaConnection` related scenario, see Inserting data in mother/daughter tables on page 2426.
**tNetezzaInput**

Reads a database and extracts fields from a Netezza database based on a query.

tNetezzaInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tNetezzaInput Standard properties**

These properties are used to configure tNetezzaInput running in the Standard Job framework.

The Standard tNetezzaInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="icon.png" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>

<td>Name of the Netezza database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table into which the data is to be inserted.</td>
</tr>
<tr>
<td><strong>Action on table</strong></td>
<td>On the table defined, you can perform one of the following operations before loading the data:</td>
</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create a table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create a table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted before the data is loaded.</td>
</tr>
<tr>
<td></td>
<td><strong>Truncate table</strong>: executes a truncate statement prior to loading the data to clear the entire content of the table.</td>
</tr>
</tbody>
</table>
### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click *Edit schema* to make changes to the schema. If the current schema is of the *Repository* type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to *Built-in* for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select *No* upon completion and choose this schema metadata again in the *Repository Content* window.

### Data file

Full path to the data file to be used. If this component is used on its own (not connected to another component with input flow) then this is the name of an existing data file to be loaded into the database. If it is connected, with an input flow to another component; this is the name of the file to be generated and written with the incoming data to later be used with nzload to load into the database.

### Use named-pipe

Select this check box to use a named-pipe instead of a data file. This option can only be used when the component is connected with an input flow to another component. When the check box is selected, no data file is generated and the data is transferred to nzload through a named-pipe. This option greatly improves performance in both Linux and Windows.

**Note:**

This component on named-pipe mode uses a JNI interface to create and write to a named-pipe on any Windows platform. Therefore the path to the associated JNI DLL must be configured inside the java library path. The component comes with two DLLs for both 32 and 64 bit operating systems that are automatically provided in the Studio with the component.

### Named-pipe name

Specify a name for the named-pipe to be used. Ensure that the name entered is valid.
## Advanced settings

<table>
<thead>
<tr>
<th><strong>Advanced settings</strong></th>
<th><strong>Description</strong></th>

This component can be used as a standalone or an output component. |

Parameters

The following table lists the parameters you can use in the Advanced options table in the Advanced settings tab.

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>-if</td>
<td>Name of the log file to generate. The logs will be appended if the log file already exists. If the parameter is not specified, the default name for the log file is <code>&lt;table_name&gt;.&lt;db_name&gt;.nzlog</code>. And it’s generated under the current working directory where the job is running.</td>
</tr>
<tr>
<td>-bf</td>
<td>Name of the bad file to generate. The bad file contains all the records that could not be loaded due to an internal Netezza error. The records will be appended if the bad file already exists. If the parameter is not specified, the default name for the bad file is <code>&lt;table_name&gt;.&lt;db_name&gt;.nzbad</code>. And it’s generated under the current working directory where the job is running.</td>
</tr>
<tr>
<td>-outputDir</td>
<td>Directory path to where the log and the bad file are generated. If the parameter is not specified the files are generated under the current working directory.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>--------------------</td>
<td>-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>-logFileSize</code></td>
<td>Maximum size for the log file. The value is in MB. The default value is 2000 or 2GB. To save hard disk space, specify a smaller amount if your job runs often.</td>
</tr>
<tr>
<td><code>-compress</code></td>
<td>Specify this option if the data file is compressed. Valid values are &quot;TRUE&quot; or &quot;FALSE&quot;. Default value if &quot;FALSE&quot;. This option is only valid if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td><code>-skipRows &lt;n&gt;</code></td>
<td>Number of rows to skip from the beginning of the data file. Set the value to &quot;1&quot; if you like to skip the header row from the data file. The default value is &quot;0&quot;. This option should only be used if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td><code>-maxRows &lt;n&gt;</code></td>
<td>Maximum number of rows to load from the data file. This option should only be used if this component is used by itself and not connected to another component via an input flow.</td>
</tr>
<tr>
<td><code>-maxErrors</code></td>
<td>Maximum number of error records to allow before terminating the load process. The default value is &quot;1&quot;.</td>
</tr>
<tr>
<td><code>-ignoreZero</code></td>
<td>Binary zero bytes in the input data will generate errors. Set this option to &quot;NO&quot; to generate error or to &quot;YES&quot; to ignore zero bytes. The default value is &quot;NO&quot;.</td>
</tr>
<tr>
<td><code>-requireQuotes</code></td>
<td>This option requires all the values to be wrapped in quotes. The default value is &quot;FALSE&quot;. This option currently does not work with input flow. Use this option only in standalone mode with an existing file.</td>
</tr>
<tr>
<td><code>-nullValue &lt;token&gt;</code></td>
<td>Specify the token to indicate a null value in the data file. The default value is &quot;NULL&quot;. To improve slightly performance you can set this value to an empty field by specifying the value as single quotes: &quot;&quot;&quot;.</td>
</tr>
<tr>
<td><code>-fillRecord</code></td>
<td>Treat missing trailing input fields as null. You do not need to specify a value for this option in the value field of the table. This option is not turned on by default, therefore input fields must match exactly all the columns of the table by default. Trailing input fields must be nullable in the database.</td>
</tr>
<tr>
<td><code>-ctrlChar</code></td>
<td>Accept control chars in char/varchar fields (must escape NULL, CR and LF). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td><code>-ctlnString</code></td>
<td>Accept un-escaped CR in char/varchar fields (LF becomes only end of row). You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>-------------</td>
<td>-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td><code>-truncString</code></td>
<td>Truncate any string value that exceeds its declared char/varchar storage. You do not need to specify a value for this option in the value field of the table. This option is turned off by default.</td>
</tr>
<tr>
<td><code>-dateStyle</code></td>
<td>Specify the date format in which the input data is written in. Valid values are: “YMD”, “Y2MD”, “DMY”, “DMY2”, “MDY”, “MONDYM”, “MONDYM2”. The default value is “YMD”.</td>
</tr>
<tr>
<td><code>-dateDelim</code></td>
<td>Delimiter character between date parts. The default value is “:” for all date styles except for “MONDYM[2]” which is “ ” (empty space).</td>
</tr>
<tr>
<td><code>-y2Base</code></td>
<td>First year expressible using two digit year (Y2) dateStyle.</td>
</tr>
<tr>
<td><code>-timeStyle</code></td>
<td>Specify the time format in which the input data is written in. Valid values are: “24HOUR” and “12HOUR”. The default value is “24HOUR”. For slightly better performance you should keep the default value.</td>
</tr>
<tr>
<td><code>-timeDelim</code></td>
<td>Delimiter character between time parts. The default value is “:”.</td>
</tr>
<tr>
<td><code>-timeRoundNanos</code></td>
<td>Allow but round non-zero digits with smaller than microsecond resolution.</td>
</tr>
<tr>
<td><code>-boolStyle</code></td>
<td>Specify the format in which Boolean data is written in the data. Valid values are: “1_0”, “T_F”, “Y_N”, “TRUE_FALSE”, “YES”. The default value is “1_0”. For slightly better performance keep the default value.</td>
</tr>
<tr>
<td><code>-allowRelay</code></td>
<td>Allow load to continue after one or more SPU reset or failed over. The default behaviour is not allowed.</td>
</tr>
</tbody>
</table>
**Loading DATE, TIME and TIMESTAMP columns**

When this component is used with an input flow, the date format specified inside the component’s schema must match the value specified for `-dateStyle`, `-dateDelim`, `-timeStyle`, and `-timeDelim` options.

<table>

</tbody>
</table>

**Related scenario**

For a related use case, see [Inserting data in bulk in MySQL database](#) on page 2489.
tNetezzaOutput

Writes, updates, makes changes or suppresses entries in a Netezza database.

tNetezzaOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the designed Job.

**tNetezzaOutput Standard properties**

These properties are used to configure tNetezzaOutput running in the Standard Job framework.

The Standard tNetezzaOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Table</td>
<td>Name of the table to be written. Note that only one table can be written at a time</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations: 

- **Default**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create a table if not exists**: The table is created if it does not exist.
- **Drop a table if exists and create**: The table is removed if it already exists and created again.
- **Clear a table**: The table content is deleted. |
| **Action on data** | On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, job stops.
- **Update**: Make changes to existing entries.
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
- **Delete**: Remove entries corresponding to the input flow. |
**Warning:**

It is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the **Advanced settings** view where you can simultaneously define primary keys for the **Update** and **Delete** operations. To do that: Select the **Use field options** check box and then in the **Key in update column**, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the **Key in delete column** for the Delete operation.

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

| **Built-In:** You create and store the schema locally for this component only. |
| **Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No upon completion** and choose this schema metadata again in the **Repository Content** window.

| **Die on error** |
| This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link. |

**Advanced settings**

| **Additional JDBC parameters** |
| Specify additional connection properties for the DB connection you are creating. This option is not available if |
you have selected the **Use an existing connection** check box in the **Basic settings**.

**Note:**
You can press **Ctrl+Space** to access a list of predefined global variables.

<table>
<thead>
<tr>
<th><strong>Use Batch</strong></th>
<th>Select this check box to activate the batch mode for data processing.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at executions.</td>
</tr>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.</td>
</tr>
<tr>
<td><strong>Name</strong></td>
<td>Type in the name of the schema column to be altered or inserted as new column</td>
</tr>
<tr>
<td><strong>SQL expression</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td><strong>Reference column</strong></td>
<td>Type in a column of reference that the <strong>tDBOutput</strong> can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td><strong>Use field options</strong></td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th><strong>Global Variables</strong></th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**tNetezzaOutput**

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

**Usage**

**Usage rule**

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Netezza database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of *tMySqlOutput* in use, see Retrieving data in error with a Reject link on page 2474.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see *Talend Studio User Guide*.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also...
Related scenarios

For tNetezzaOutput related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2466.
tNetezzaRollback

Cancels the transaction committed in the connected Netezza database to avoid committing part of a transaction involuntarily.

**tNetezzaRollback Standard properties**

These properties are used to configure tNetezzaRollback running in the Standard Job framework.

The Standard tNetezzaRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tNetezzaConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tNetezza* components, especially with the tNetezzaConnection and tNetezzaCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. <td>Name of the database</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
**Built-In**: You create and store the schema locally for this component only.  
**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Table Name** | Enter the name of the table to be processed. |
| **Query type** | Either **Built-in** or **Repository**.  
**Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder  
**Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejection** link. |
## Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong>.</th>
</tr>
</thead>
</table>
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.  

**Note:**  
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by '?' in the SQL instruction of the **Query** field in the **Basic Settings** tab.  

**Parameter Index:** Enter the parameter position in the SQL instruction.  

**Parameter Type:** Enter the parameter type.  

**Parameter Value:** Enter the parameter value.  

**Note:**  
This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

## Global Variables

| **Global Variables** |  
QUERY: the query statement being processed. This is a Flow variable and it returns a string.  

NB_EFFECTED: the number of effected rows. This is an After variable and it returns an integer.  

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

### Global Variables

| Global Variables | **NB_LINE_UPDATED:** the number of rows updated. This is an After variable and it returns an integer.  
**NB_LINE_INSERTED:** the number of rows inserted. This is an After variable and it returns an integer.  
**NB_LINE_REJECTED:** the number of rows rejected. This is an After variable and it returns an integer.  
**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
|-----------------|-------------------------------------------------------------------------------------------------------------------|
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as an Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Limitation</td>
<td>This component does not support using SCD type 0 together with other SCD types.</td>
</tr>
</tbody>
</table>

### Related scenario

For related scenarios, see tMysqlSCD on page 2508.
tNetsuiteConnection

Creates a connection to the NetSuite SOAP server so that other NetSuite components in the Job can reuse the connection.

tNetsuiteConnection Standard properties

These properties are used to configure tNetsuiteConnection running in the Standard Job framework.
The Standard tNetsuiteConnection component belongs to the Business family.
The component in this framework is available in all Talend products.

Basic settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint</td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td>API version</td>
<td>Select the version of the NetSuite API you are connecting to. As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>
</tr>
<tr>
<td>E-mail and Password</td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>

</tbody>
</table>

Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable customizations</td>
<td>Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the Record Type dialog box, and custom fields will be retrieved and included into the schema. This option is enabled by default. You can disable it if you don’t need custom record types or custom fields. With this option enabled in the tNetsuiteConnection component, all the other components using this connection will have this option enabled.</td>
</tr>
</tbody>
</table>
**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

### Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

---

### Usage

| Usage rule | This component is more commonly used with other NetSuite components. |

---

### Related scenario

No scenario is available for this component yet.
**tNetsuiteInput**

Invokes the NetSuite SOAP service and retrieves data according to the conditions you specify.

**tNetsuiteInput Standard properties**

These properties are used to configure tNetsuiteInput running in the Standard Job framework.

The Standard tNetsuiteInput component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint</td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td>API version</td>
<td>Select the version of the NetSuite API you are connecting to. As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>

<tr>
<td>E-mail and Password</td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Role</td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td>Account</td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td>Application ID</td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
<tr>
<td>Record Type</td>
<td>Click the [...] button next to the field to open a dialog box, and then select a record type you want to retrieve or select the Use custom object check box and specify a custom record type in the Object Name field.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Warning**: The schema of this component is dynamically filled with columns corresponding to the NetSuite service fields, which vary depending on the **Record Type** selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors.

**Search conditions**

Define search conditions to match fields for data retrieval. Click the [+] button to add as many rows as you need, each row for a condition, and define each of your conditions:

- **Field**: select a field to search based on the condition.
- **Operator**: select an operator for the field search condition.
- **Value**: enter the value for the field search condition.
- **Value 2**: enter the second value for the field search condition, if relevant depending on the operator you select.

**Advanced settings**

**Body fields only**

Select this check box to retrieve only body fields.
Clear this check box to retrieve body fields and sublist values.

**Enable customizations**

Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the **Record Type** dialog box, and custom fields will be retrieved and included into the schema.

This option is enabled by default. You can disable it if you don’t need custom record types or custom fields.
tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Usage

| Usage rule | This component is usually used as a start component in a Talend flow and it requires an output component. |

Handling data with NetSuite

This scenario describes a Job that reads data from NetSuite, transforms the data and writes the transformed data to NetSuite, finally displays the transformed data on the console.

![Diagram](image)

Adding the components

Create a new Job and add the following five components by typing their names in the design workspace or dropping them from the Palette:
• two tNetsuiteInput components: to read data that matches the specified search criteria from the NetSuite server.
• a tMap component: to transform the input data to the output structure.
• a tNetsuiteOutput component: to write the transformed data into the NetSuite server.
• a tLogRow component: to display the data received from the NetSuite server.

Configuring and linking the components

Reading, transforming, and writing data in NetSuite

Procedure

1. Double-click the first tNetsuiteInput to open its Basic settings view.

![Image of tNetsuiteInput settings]

2. In the Endpoint, API version, E-mail, Password, Role, Account, and Application ID fields, enter the information required to access NetSuite.

3. Click the [...] button next to the Record Type field, and from the dialog box that opens select Location to read the location type information from NetSuite.

   The schema corresponding to the location record type is automatically retrieved.

4. Define a search condition.
   a) Click the [+] button below the Search conditions table to add one row.
   b) Click the cell of the Field column and select internalId from the drop-down list.
   c) Click the cell of the Operator column and select List - Any Of from the drop-down list.
   d) In the cell of the Value column, enter java.util.Arrays.asList("1") to retrieve only the record whose internalId is set to 1.

5. Connect the first tNetsuiteInput to tMap using a Row > Main connection.

6. Double-click tNetsuiteOutput to open its Basic settings view.
7. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

8. In the **Action** list, select **insert** to insert the transformed data into NetSuite.

9. Click the ** [...] ** button next to the **Record Type** field, and in the dialog box that opens select **Location** to write the location type information into NetSuite.

10. Click the ** [...] ** button next to **Edit schema** to open the schema editor. You can see the schema has already been prefilled. Keep only the columns that are relevant to your operation and delete others. In this example, keep the column **Name**, **Parent**, **IncludeChildren**, **IsInactive**, **TranPrefix**, **Logo**, **MakeInventoryAvailable**, **MakeInventoryAvailableStore**, **CustomFieldList**, and **ExternalId**.

11. Connect **tMap** to **tNetsuiteOutput** using a **Row > "New Output" (Main)** connection. In the pop-up dialog box, enter the name of the output connection, *out* in this example. Then click **Yes** to let **tMap** get the schema of the target component **tNetsuiteOutput**.

12. Double-click **tMap** to open its **Map Editor** and configure data flow mappings.
a) In the \textit{out} output table, set the value of the \textbf{Name} column by entering "Paris" in the corresponding \textit{Expression} column field.

b) Drag and drop the \textit{Parent} column in the \textit{row1} input table onto the \textit{Expression} column of the corresponding row in the \textit{out} output table.

c) Do the same to drag and drop other columns \textit{IncludeChildren}, \textit{IsInactive}, \textit{TranPrefix}, \textit{Logo}, \textit{MakeInventoryAvailable}, \textit{MakeInventoryAvailableStore}, \textit{CustomFieldList}, and \textit{ExternalId} in the \textit{row1} input table onto the \textit{Expression} column of the corresponding row in the \textit{out} output table.

\textbf{Retrieving the transformed data from NetSuite}

\textbf{Procedure}

1. Double-click the second \texttt{tNetsuitelnput} to open its \textit{Basic settings} view.
2. In the **Endpoint**, **API version**, **E-mail**, **Password**, **Role**, **Account**, and **Application ID** fields, enter the information required to access NetSuite.

3. Click the [...] button next to the **Record Type** field, and from the dialog box that opens select **Location** to read the location type information from NetSuite.

   The schema corresponding to the location record type is automatically retrieved.

4. Define a search condition.
   a) Click the [+] button below the **Search condition** table to add one row.
   b) Click the cell of the **Field** column and select **name** from the drop-down list.
   c) Click the cell of the **Operator** column and select **String - Contains** from the drop-down list.
   d) In the cell of the **Value** column, enter **Paris** to retrieve only the record whose **name** contains **Paris**.

5. Double-click **tLogRow** to open its **Basic settings** view.

6. In the **Mode** area, select **Vertical (each row is a key/value list)** for better readability of the result.

7. Connect the second **tNetsuiteInput** to **tLogRow** using a **Row > Main** connection.

8. Connect the first **tNetsuiteInput** to the second **tNetsuiteInput** using a **Trigger > OnSubjobOk** connection.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** or click **Run** on the **Run** tab to run the Job.

As shown above, the data has been transformed and written into NetSuite, then the transformed data is retrieved from NetSuite and displayed on the console.
**tNetsuiteOutput**

Invokes the NetSuite SOAP service and inserts, updates, or removes data on the NetSuite SOAP server.

**tNetsuiteOutput Standard properties**

These properties are used to configure tNetsuiteOutput running in the Standard Job framework.

The Standard tNetsuiteOutput component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select a tNetsuiteConnection component to reuse its connection details to set up the connection to the NetSuite server. With a tNetsuiteConnection selected, the settings related to connection setup will not be displayed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Endpoint</td>
<td>Enter the WebService URL required to connect to the NetSuite server.</td>
</tr>
<tr>
<td>API version</td>
<td>Select the version of the NetSuite API you are connecting to. As of version 7.1, API versions 2014.2 and 2016.2 have been deprecated.</td>
</tr>
<tr>
<td>E-mail and Password</td>
<td>Enter your user credentials to access the NetSuite SOAP service. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Role</td>
<td>Enter your NetSuite role ID.</td>
</tr>
<tr>
<td>Account</td>
<td>Enter your NetSuite web services account number (also called account ID).</td>
</tr>
<tr>
<td>Application ID</td>
<td>Enter the NetSuite application ID generated for your account. An application ID is required starting from NetSuite version 2015 and above. You can find your application ID or create a new one on NetSuite’s Manage Integration page.</td>
</tr>
<tr>
<td>Record Type</td>
<td>Click the [...] button next to the field to open a dialog box, and then select a record type you want to retrieve or select the Use custom object check box and specify a custom record type in the Object Name field.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>---</td>
<td></td>
</tr>
</tbody>
</table>
| **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com). |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Warning:**
The schema of this component is prefilled with columns corresponding to the NetSuite service fields, which vary depending on the **Record Type** selected. You can delete columns that are not relevant to your operation, but do not rename any schema columns or this may cause execution errors.

<table>
<thead>
<tr>
<th><strong>Action</strong></th>
<th>Select an action to perform from the list.</th>
</tr>
</thead>
</table>
| **Add**: Adds a new record to your data. If a duplicate is found and the **Die on error** check box is selected, the Job stops; if the **Die on error** check box is cleared, the duplicate is ignored and the Job continues.  
**Update**: Makes changes to an existing record.  
If the record corresponding to the specified **Internal ID** does not exist, and the **Die on error** check box is selected, the Job stops.  
To use this option, the **InternalId** column must exist in the schema and set as Key.  
**Upsert**: Updates the record corresponding to the specified ID, or inserts a new record if it does not exist.  
To use this option, a column for record ID must exist in the schema and set as Key.  
**Delete**: Removes an existing record. |
If the record corresponding to the specified Internal ID does not exist and the Die on error check box is selected, the Job stops.

To use this option, the InternalId column must exist in the schema and set as Key.

### Sync outgoing schema

After the component schema is updated, click this button to propagate the schema to the outgoing flow(s), which can be a normal flow, a reject flow, or both, if the component has any.

### Advanced settings

#### Enable customizations

Select this check box to instruct the component to retrieve customizations - custom record types and custom fields. With this option enabled, custom record types will be retrieved and can be selected in the Record Type dialog box, and custom fields will be retrieved and included into the schema.

This option is enabled by default. You can disable it if you don’t need custom record types or custom fields.

#### Use native Upsert operation

Select this check box to use the Upsert operation provided by NetSuite.

To use NetSuite’s Upsert operation, the ExternalId column must exist in the schema and set as Key.

This option is available when Upsert is selected from the Action list in Basic settings.

By default, for compatibility reasons, this option is disabled and the component performs the Add or Update action for an upsert depending on whether the record ID is specified.

#### Batch size

Specify the number of records to be processed in each batch.

Note that batching will be disabled if the output component has an outgoing flow.

#### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>CURRENT_INTERNALID: The internal ID of the record currently inserted or processed. This is a Flow variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

2665
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component is usually used as an end component in a Talend flow and it requires an input component. |

### Related scenario

For a related scenario, see *Handling data with NetSuite* on page 2657.
tNormalize

Normalizes the input flow following SQL standard to help improve data quality and thus eases the data update.

tNormalize Standard properties

These properties are used to configure tNormalize running in the Standard Job framework.
The Standard tNormalize component belongs to the Processing family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td>---</td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td>---</td>
</tr>
<tr>
<td>Column to normalize</td>
<td>Select the column from the input flow which the normalization is based on.</td>
</tr>
<tr>
<td>Item separator</td>
<td>Enter the separator which will delimit data in the input flow.</td>
</tr>
</tbody>
</table>

Note:
The item separator is based on regular expressions, so the character ‘.’ (a special character for regular expression) should be avoided or used carefully here.
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Get rid of duplicated rows from output</td>
<td>Select this check box to deduplicate rows in the data of the output flow.</td>
</tr>
<tr>
<td>Use CSV parameters</td>
<td>Select this check box to include CSV specific parameters such as escape mode and enclosure character.</td>
</tr>
<tr>
<td>Discard the trailing empty strings</td>
<td>Select this check box to discard the trailing empty strings.</td>
</tr>
<tr>
<td>Trim resulting values</td>
<td>Select this check box to trim leading and trailing whitespace from the resulting data.</td>
</tr>
<tr>
<td><strong>Note:</strong></td>
<td>When both Discard the trailing empty string and Trim resulting values check boxes are selected, the former works first.</td>
</tr>
</tbody>
</table>

### Global Variables

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

**Usage rule**

This component can be used as intermediate step in a data flow.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
Normalizing data

This simple scenario illustrates a Job that normalizes a list of tags for Web forum topics, and displays the result in a table on the Run console.

This list is not well organized and it contains trailing empty strings, leading and trailing whitespace, and repeated tags, as shown below.

ldap,  
   db2, jdbc driver,  
grid computing,  talend architecture ,  
content, environment,,  
tmap,,  
eclipse,  
database, java, postgresql,  
tmap,  
database, java, sybase,  
deployment,,  
repository,  
database, informix, java

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: tFileInputDelimited, tNormalize, tLogRow.
2. Connect the components using Row > Main connections.

Configuring the components

Procedure

1. Double-click the tFileInputDelimited component to open its Basic settings view.

2. In the File name field, specify the path to the input file to be normalized.
3. Click the [...] button next to Edit schema to open the Schema dialog box, and set up the input schema by adding one column named Tags. When done, click OK to validate your schema setup and close the dialog box, leaving the rest of the settings as they are.

4. Double-click the tNormalize component to open Basic settings view.

5. Check the schema, and if necessary, click Sync columns to get the schema synchronized with the input component.

6. Define the column the normalization operation is based on.
   In this use case, the input schema has only one column, Tags, so just accept the default setting.

7. In the Advanced settings view, select the Get rid of duplicate rows from output, Discard the trailing empty strings, and Trim resulting values check boxes.

8. In the tLogRow component, select the Print values in the cells of table radio button.
**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Click **Run** on the Run tab or press **F6** to execute the Job.

The list is tidied up, with duplicate tags, leading and trailing whitespace and trailing empty strings removed, and the result is displayed in a table cell on the console.
tOpenbravoERPInput

Extracts data from OpenBravoERP database according to the conditions defined in specific columns.
tOpenbravoERPInput connects to an OpenbravoERP database entity via the appropriate Web service.

**tOpenbravoERPInput Standard properties**

These properties are used to configure tOpenbravoERPInput running in the Standard Job framework. The Standard tOpenbravoERPInput component belongs to the Business family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

<td>Click Sync columns to retrieve the schema from the previous component connected in the Job.</td>
</tr>
</tbody>
</table>

**Note:**
For this component, the schema corresponds to a selected entity.

WHERE Clause
Enter your WHERE clause.
### Order by
Select this check box to define how to order the results (the elements in the drop-down list depend on the entity selected).

**Sort:** Choose whether to organise the results in either **Ascending** or **Descending** order.

### First result
Enter the row number you want to retrieve first.

### Max result
Enter the maximum number of results you want to retrieve.

### Advanced settings

| Advanced separator (for numbers) | Select this check box to modify the separators to be used for the numbers. Either:  
|---------------------------------|------------------------------------------------|
|                                 | **Thousands separator**  
|                                 | or  
|                                 | **Decimal separator**  

| tStatCatcher Statistics | Select this check box to collect the log data at a component level. |

### Global Variables

| Global Variables | **NB_LINE:** the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
|------------------|-----------------------------------------------------------------|
|                  | **ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
|                  | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
|                  | For further information about variables, see **Talend Studio User Guide**. |

### Usage

| Usage rule | This component is generally used as an input component. An output component is required. |

### Related Scenario

For a scenario in which **tOpenbravoERPIInput** might be used, see **Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows** on page 2217.
tOpenbravoERPOutput

Writes data in an OpenbravoERP database.

**tOpenbravoERPOutput** writes an object in an OpenbravoERP database via the appropriate Web service.

**tOpenbravoERPOutput Standard properties**

These properties are used to configure tOpenbravoERPOutput running in the Standard Job framework. The Standard tOpenbravoERPOutput component belongs to the Business family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Openbravo REST Webservice URL</strong></td>
<td>Enter the URL of the Web service that allows you to connect to the OpenbravoERP database.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>User authentication information. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Action on data</strong></td>
<td>From the list, select the one of the following actions: Update/Create or Remove</td>
</tr>
<tr>
<td><strong>Use existing data file</strong></td>
<td>Select this check box if desired and then select the file by browsing your directory.</td>
</tr>
<tr>
<td><strong>Entity</strong></td>
<td>Select the appropriate entity from the drop-down list.</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema**      | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

</tbody>
</table>

### Usage

| Usage rule | This component is used as an output component. It requires an input component.                                                                                                             |

### Related scenario

For a scenario in which **tOpenbravoERPOutput** may be used, see [Writing data in a Microsoft CRM database and putting conditions on columns to extract specified rows](#) on page 2217.
**tOracleBulkExec**

Offers gains in performance during operations performed on data of an Oracle database.

tOracleBulkExec inserts, appends, replaces or truncate data in an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tOracleBulkExec Standard properties**

These properties are used to configure tOracleBulkExec running in the Standard Job framework.

The Standard tOracleBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version in use. |
| **Host** | IP address of the database server. |
| **Port** | Port number listening the database server. |
| **Database** | Database name. |
| **Schema** | Schema name. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |

<table>
<thead>
<tr>
<th><strong>Action on table</strong></th>
<th>On the table defined, you can perform one of the following operations:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>None</strong></td>
<td>No operation is carried out.</td>
</tr>
<tr>
<td><strong>Drop and create table</strong></td>
<td>The table is removed and created again.</td>
</tr>
<tr>
<td><strong>Create table</strong></td>
<td>The table does not exist and gets created.</td>
</tr>
<tr>
<td><strong>Create table if not exists</strong></td>
<td>The table is created if it does not exist.</td>
</tr>
<tr>
<td><strong>Drop table if exists and create</strong></td>
<td>The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td><strong>Clear table</strong></td>
<td>The table content is deleted.</td>
</tr>
<tr>
<td><strong>Truncate table</strong></td>
<td>The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
</tbody>
</table>

| **Data file name** | Name of the file to be loaded. |
| **Warning:** | This file should be located on the same machine as the Jobserver. |

| **Action on data** | On the data of the table defined, you can perform: |
**Insert:** Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.

**Update:** Update the existing data. You have to set the key on the schema if this option is selected.

**Append:** Append data to the table, whether the table is empty or not.

**Replace:** If the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.

**Truncate:** If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Built-In

You create and store the schema locally for this component only.

### Repository

You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Advanced settings

<table>
<thead>
<tr>
<th>Advanced separator (for number)</th>
<th>Select this check box to change the separator used for the numbers.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing control file</td>
<td>Select this check box if you use a control file (.ctl) and specify its path in the <strong>.ctl file name</strong> field.</td>
</tr>
<tr>
<td>Record format</td>
<td>Define the record format: <strong>Default:</strong> format parameters are set by default.</td>
</tr>
<tr>
<td><strong>Stream</strong></td>
<td>set Record terminator.</td>
</tr>
<tr>
<td><strong>Fixed</strong></td>
<td>set the Record length.</td>
</tr>
<tr>
<td><strong>Variable</strong></td>
<td>set the Field size of the record length.</td>
</tr>
</tbody>
</table>

**Specify .ctl file's INTO TABLE clause manually**
Select this check box to manually fill in the INTO TABLE clause of the control file.

**Fields terminated by**
Character, string or regular expression to separate fields:
- **None**: no separator is used.
- **Whitespace**: the separator used is a space.
- **EOF (used for loading LOBs from lobfile)**: the separator used is an EOF character (End Of File).
- **Other terminator**: Set another terminator in the Field terminator field.

**Use fields enclosure**
Select this check box if you want to use enclosing characters for the text:
- **Fields enclosure (left part)**: character delimiting the left of the field.
- **Field enclosure (right part)**: character delimiting the right of the field.

**Use schema's Date Pattern to load Date field**
Select this check box to use the date pattern of the schema in the date field.

**Specify field condition**
Select this check box to define data loading condition.

**Preserve blanks**
Select this check box to preserve the blanks.

**Trailing null columns**
Select this check box to load null columns.

**Load options**
Click + to add data loading options:
- **Parameter**: select a loading parameter from the list.
- **Value**: enter a value for the parameter selected.

**NLS Language**
In the list, select the language used for the data that are not used in Unicode.

**Set Parameter NLS_TERRITORY**
Select this check box to modify the territory conventions used for day and weeks numbering. Your OS value is the default value used.

**Encoding**
Select the encoding from the list, or enter the encoding between double quotes if it does not exist in the list. This field is compulsory for database data handling.

**Output**
Select the type of output for the standard output of the Oracle database:
- to console.
- to global variable.

**Convert columns and table names to uppercase**
Select this check box to uppercase the names of the columns and the name of the table.
Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE_DATA: the number of rows read. This is an After variable and it returns an integer.</th>

<tr>
<td></td>
<td>For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Limitation

The database server/client must be installed on the same machine where the Studio is installed or where the Job using tOracleBulkExec is deployed, so that the component functions properly.

Truncating and inserting file data into an Oracle database

This scenario describes how to truncate the content of an Oracle database and load the content of an input file. The related Job is composed of three components that respectively creates the content, output this content into a file to be loaded into the Oracle database after the database table has been truncated.

Building the Job

Procedure

1. Drop the following components: tOracleInput, tFileOutputDelimited and tOracleBulkExec from the Palette to the design workspace.
2. Connect the tOracleInput to the tFileOutputDelimited using a Row > Main link.
3. Connect the tOracleInput to the tOracleBulkExec using a OnSubjobOk trigger link.

Results

Configuring the components

Procedure

1. Double-click the tOracleInput to open its Basic settings view.
2. Define the Oracle connection details. It is recommended to store the database connection details in the Metadata folder of the Repository tree view in order to retrieve them easily at any time in any Job.
3. Define the schema, if it is not stored in the **Repository**. In this example, the schema contains four columns as follows: `ID_Contract`, `ID_Client`, `Contract_type` and `Contract_Value`.

4. Define the **tFileOutputDelimited** component parameters, including output **File Name**, **Row separator**, and **Fields delimiter**.

5. Double-click on the **tOracleBulkExec** to define the database populating properties.

6. In the **Property Type** list, select **Repository** if you stored the database connection details under the **Metadata** node of the **Repository** or select **Built-in** to define them manually. In this scenario, use the **Built-in** mode.

7. Set the connection parameters in the following fields: **Host**, **Port**, **Database**, **Schema**, **Username**, and **Password**.

8. Fill in the name of the **Table** to be populated and the **Action on data** to be carried out. In this use case, select **insert**.

9. In the **Schema** list, select **Built-in**, and click the `[...]` button next to the **Edit schema** field to define the structure of the data to be passed to the next component.

10. Click the **Advanced settings** view to configure the advanced settings of the component.
11. Select the **Use an existing control file** check box if you want to use a control file (.ctl) storing the status of the physical structure of the database. Or, fill in the following fields manually: **Record format**, **Specify .ctl file's INTO TABLE clause manually**, **Field terminated by**, **Use fields enclosure**, **Use schema's Date Pattern to load Date field**, **Specify field condition**, **Preserve blanks**, **Trailing null columns**, **Load options**, **NLS Language** and **Set Parameter NLS_TERRITORY** according to your database.

12. In the **Encoding** list, select the encoding, or enter the encoding between double quotes if it does not exist in the list.

13. In the **Output** list, select **to console** to output the standard output of the database in the console.

**Executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.

2. Press **F6** to run the Job. The log is shown in the console of the **Run** view and the table is populated with the parameter file data.

**Results**

Related topic: see **Inserting data in bulk in MySQL database** on page 2489.
**tOracleClose**

Closes the transaction committed in the connected Oracle database.

**tOracleClose Standard properties**

These properties are used to configure tOracleClose running in the Standard Job framework.

The Standard tOracleClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the connection component of interest if more than one connection is planned for the current Job.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

**Usage rule**

This component is to be used along with Oracle components, especially with tOracleConnection and tOracleCommit.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenarios

No scenario is available for the Standard version of this component yet.
**tOracleCommit**

Validates the data processed through the Job into the connected Oracle database

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch and thus provides gain in performance.

**tOracleCommit Standard properties**

These properties are used to configure tOracleCommit running in the Standard Job framework.

The Standard tOracleCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tOracleCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStatCatcher Statistics                       | Select this check box to collect log data at the component level. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is more commonly used with other tOracle* components, especially with the tOracleConnection and tOracleRollback components.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces</td>
</tr>
</tbody>
</table>
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tOracleCommit related scenario, see Inserting data in mother/daughter tables on page 2426
**tOracleConnection**

Opens a connection to the specified Oracle database for reuse in the subsequent subJob or subJobs.

**tOracleConnection Standard properties**

These properties are used to configure tOracleConnection running in the Standard Job framework.

The Standard tOracleConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Use SSL</td>
<td>Select this check box to use the SSL protocol to protect the communication with your database server.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when ORACLE CUSTOM is selected from the Connection Type drop-down list and Oracle 12-7 is selected from the DB Version drop-down list.</td>
</tr>
<tr>
<td>TrustStore file</td>
<td>The path to the TrustStore file used to authenticate your database server in SSL authentication.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when the Use SSL check box is selected.</td>
</tr>
<tr>
<td>TrustStore password</td>
<td>The password for the TrustStore file.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when the Use SSL check box is selected.</td>
</tr>
<tr>
<td>Need Client authentication</td>
<td>Select this check box if SSL client authentication is needed.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when the Use SSL check box is selected.</td>
</tr>
<tr>
<td>KeyStore file</td>
<td>The path to the keystore file used for SSL client authentication.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when the Need Client authentication check box is selected.</td>
</tr>
<tr>
<td>KeyStore password</td>
<td>The password for the KeyStore file.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td></td>
<td>This property is available only when the Need Client authentication check box is selected.</td>
</tr>
<tr>
<td>Disable CBC protection</td>
<td>Select this check box to disable the use of CBC (Cipher Block Chaining) in SSL authentication.</td>
</tr>
</tbody>
</table>
This property is available only when the **Use SSL** check box is selected.

### Additional JDBC parameters
Specify additional connection properties for the DB connection you are creating.

**Note:**
You can set the encoding parameters through this field.

### Use or register a shared DB Connection
Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

### Specify a data source alias
Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

### Advanced settings

#### Auto Commit
Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.

#### tStatCatcher Statistics
Select this check box to gather the job processing metadata at a Job level as well as at each component level.
Usage

| Usage rule | This component is more commonly used with other tOracle* components, especially with the tOracleCommit and tOracleRollback components. |

Related scenario

For **tOracleConnection** related scenario, see **tMysqlConnection** on page 2425
tOracleInput

Reads an Oracle database and extracts fields based on a query.

tOracleInput executes a database query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

**tOracleInput Standard properties**

These properties are used to configure tOracleInput running in the Standard Job framework.

The Standard tOracleInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| Property type | Either **Built-In** or **Repository**.  
**Built-In:** No property data stored centrally.  
**Repository:** Select the repository file where the properties are stored. |
| ![icon] | Click this icon to open a database connection wizard and store the database connection parameters you set in the component **Basic settings** view.  
For more information about setting up and storing database connection parameters, see Talend Studio User Guide. |
| Use an existing connection | Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined. |

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Connection type</strong></th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>WALLET</strong></td>
<td>Select this connection type to store credentials in an Oracle wallet.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
</tbody>
</table>

| **DB Version** | Select the Oracle version in use. |
| **Host** | Database server IP address. |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database. |

| **Oracle schema** | Oracle schema name. |

| **Username and Password** | DB user authentication data. |
| | To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: |
| | • **View schema**: choose this option to view the schema only. |
| | • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. |
| | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |

| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

| **Table name** | Database table name. |
### Query type and Query

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Specify a data source alias

Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*.

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

### Advanced settings

#### Additional JDBC parameters

Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, `encryption=1;clientname=Talend`.

This field is not available if the **Use an existing connection** check box is selected.

#### tStatCatcher Statistics

Select this check box to collect log data at the component level.

#### Use fetch size

Select this check box and in the **Fetch size** field displayed, specify the number of rows to fetch in one go from the database. The performance can be improved by tuning this fetch size to an appropriate value.

#### Trim all the String/Char columns

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

#### Trim column

Remove leading and trailing whitespace from defined columns.

#### No null values

Check this box to improve the performance if there are no null values.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Oracle databases.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Using context parameters when reading a table from an Oracle database

In this scenario, we will read a table from an Oracle database using a context parameter to refer to the table name.

### Dropping and linking the components

**Procedure**

1. Create a new Job and add the following components by typing their names in the design workspace or dropping them from the **Palette**: a **tOracleInput** component and a **tLogRow** component.
2. Connect **tOracleInput** to **tLogRow** using a **Row > Main** link.

![Diagram showing connection between tOracleInput and tLogRow](image)

**Configuring the components**

**Procedure**

1. Double-click **tOracleInput** to open its **Basic Settings** view in the **Component** tab.

![Oracle Input Component Settings](image)

2. Select a connection type from the **Connection Type** drop-down list. In this example, it is **Oracle SID**.
   
   Select the version of the Oracle database to be used from the **DB Version** drop-down list. In this example, it is **Oracle 12-7**.
   
   In the **Host** field, enter the Oracle database server’s IP address. In this example, it is **192.168.31.32**.
   
   In the **Database** field, enter the database name. In this example, it is **TALEND**.
   
   In the **Oracle schema** field, enter the Oracle schema name. In this example, it is **TALEND**.
   
   In the **Username** and **Password** fields, enter the authentication details.

3. Click the [...] button next to **Edit schema** to open the schema editor.
4. Click the [+] button to add four columns: ID and AGE of the integer type, NAME and SEX of the string type.

Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

5. Put the cursor in the Table Name field and press F5 for context parameter setting. The dialog box New Context Parameter pops up.

For more information about context settings, see Talend Studio User Guide.

6. In the Name field, enter the context parameter name. In this example, it is TABLE.

In the Default value field, enter the name of the Oracle database table to be queried. In this example, it is PERSON.
7. Click **Finish** to validate the setting.

The context parameter `context.TABLE` automatically appears in the **Table Name** field.

8. In the **Query Type** list, select **Built-In**. Then, click **Guess Query** to get the query statement.

   ```sql
   "SELECT +context.TABLE+."ID", +context.TABLE+.NAME, +context.TABLE+.SEX, +context.TABLE+.AGE FROM +context.TABLE
   ```

9. Double-click **tLogRow** to open its **Basic settings** view in the **Component** tab.

10. In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the results.

### Saving and executing the Job

#### Procedure

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```
[statistics] connecting to socket on port 3750
[statistics] connected

<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>ID</td>
</tr>
<tr>
<td>----</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
<tr>
<td>4</td>
</tr>
<tr>
<td>5</td>
</tr>
</tbody>
</table>

[statistics] disconnected
```

As shown above, the data in the Oracle database table *PERSON* is displayed on the console.

### Related scenarios

For related scenarios, see:
- Reading data from different MySQL databases using dynamically loaded connection parameters on page 497.
tOracleOutput

 Writes, updates, makes changes or suppresses entries in an Oracle database.

tOracleOutput executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

**tOracleOutput Standard properties**

These properties are used to configure tOracleOutput running in the Standard Job framework.

The Standard tOracleOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="Icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Connection type</th>
<th>Drop-down list of available drivers:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Oracle OCI</strong></td>
<td>Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.</td>
</tr>
<tr>
<td><strong>Oracle Custom</strong></td>
<td>Select this connection type to access a clustered database.</td>
</tr>
<tr>
<td><strong>Oracle Service Name</strong></td>
<td>Select this connection type to use the TNS alias that you give when you connect to the remote database.</td>
</tr>
<tr>
<td><strong>WALLET</strong></td>
<td>Select this connection type to store credentials in an Oracle wallet.</td>
</tr>
<tr>
<td><strong>Oracle SID</strong></td>
<td>Select this connection type to uniquely identify a particular database on a system.</td>
</tr>
</tbody>
</table>

| DB Version | Select the Oracle version in use. |
| Host | Database server IP address. |
| Port | Listening port number of DB server. |
| Database | Name of the database. |

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

| Table | Name of the table to be written. Note that only one table can be written at a time. |

**Action on table**

**Note:**

The Action on table list will not be available if you select the Enable parallel execution check box in the Advanced settings view.

On the table defined, you can perform one of the following operations:

**Default:** No operation is carried out.
<table>
<thead>
<tr>
<th>Action on data</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td><strong>Create table if does not exist</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>Truncate table with reuse storage</strong>: The table content is deleted. You do not have the possibility to rollback the operation. However, it is allowed to reuse the existing storage allocated to the table though the storage is considered empty.</td>
</tr>
</tbody>
</table>

**Warning:**
If you select the Use an existing connection check box and select an option other than Default from the Action on table list, a commit statement will be generated automatically before the data insert/update/delete operation.

<table>
<thead>
<tr>
<th>Schema and Edit schema</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action on data</strong>: On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td><strong>Insert</strong>: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td><strong>Update</strong>: Make changes to existing entries</td>
</tr>
<tr>
<td><strong>Insert or update</strong>: Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td><strong>Update or insert</strong>: Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td><strong>Delete</strong>: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>

**Warning:**
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th><strong>Built-In</strong></th>
<th>You create and store the schema locally for this component only.</th>
</tr>
</thead>
</table>
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.  
You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)). |

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your **Job** in **Talend Runtime**.

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

### Advanced settings

**Use alternate schema**

Select this option to use a schema other than the one specified by the component that establishes the database connection (that is, the component selected from the **Component list** drop-down list in **Basic settings** view). After selecting this option, provide the name of the desired schema in the **Schema** field.

This option is available when **Use an existing connection** is selected in **Basic settings** view.
### Additional JDBC parameters
Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings view.

**Note:**
You can press **Ctrl+Space** to access a list of predefined global variables.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
<tr>
<td>Additional Columns</td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or actions that require particular preprocessing.</td>
</tr>
<tr>
<td>Name:</td>
<td>Type in the name of the schema column to be altered or inserted as new column.</td>
</tr>
<tr>
<td>SQL expression:</td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td>Position:</td>
<td>Select Before, Replace, or After following the action to be performed on the reference column.</td>
</tr>
<tr>
<td>Reference column:</td>
<td>Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.</td>
</tr>
<tr>
<td>Use field options</td>
<td>Select this check box to customize a request, especially when there is double action on data.</td>
</tr>
</tbody>
</table>
| Use Hint Options | Select this check box to activate the hint configuration area which helps you optimize a query's execution. In this area, parameters are:  
  - **HINT**: specify the hint you need, using the syntax /*+ */.  
  - **POSITION**: specify where you put the hint in a SQL statement.  
  - **SQL_STMT**: select the SQL statement you need to use. |
| Convert columns and table to uppercase | Select this check box to set the names of columns and table in upper case. |
| Debug query mode | Select this check box to display each step during processing entries in a database. |
| Use Batch Size | Select this check box to activate the batch mode for data processing. |
| Batch Size | Specify the number of records to be processed in each batch. |
This field appears only when the **Use batch mode** check box is selected.

| Support null in "SQL WHERE" statement | Select this check box to validate null in "SQL WHERE" statement. |

### Global Variables

| Global Variables | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.  
**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.  
**NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.  
**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.  
**QUERY**: the query statement processed. This is an After variable and it returns a string.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#).  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

### Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.  
**Row > Rejects** This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in an Oracle database. It also allows you to create a reject flow using a link to filter data in error.  
For an example of **tMysqlOutput** in use, see [Retrieving data in error with a Reject link](#) on page 2474. |

| Dynamic settings | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable. |
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

### Related scenarios

For `tOracleOutput` related topics, see:

- Inserting a column and altering data using `tMysqlOutput` on page 2466.
tOracleOutputBulk

Wrote a file with columns based on the defined delimiter and the Oracle standards.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two-step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component, detailed in a separate section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

**tOracleOutputBulk Standard properties**

These properties are used to configure tOracleOutputBulk running in the Standard Job framework.

The Standard tOracleOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>

<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning</strong></td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
</tbody>
</table>
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only. |
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

**Advanced separator (for number)**

Select this check box to change data separators for numbers:

- **Thousands separator**: define separators you want to use for thousands.
- **Decimal separator**: define separators you want to use for decimals.

**Field separator**

Character, string or regular expression to separate fields.

**Row separator**

String (ex: `\n` on Unix) to separate rows.

**Encoding**

Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.

**Bulk file parameters**

Set the parameters **Buffer Size** and **StringBuilder Size** for a performance gain according to the memory size.

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a job level as well as at each component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is to be used along with <strong>tOracleBulkExec</strong> component. Used together they offer gains in performance while feeding an Oracle database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component family</td>
<td>Databases/Oracle</td>
</tr>
</tbody>
</table>

### Related scenarios

For use cases in relation with **tOracleOutputBulk**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tOracleOutputBulkExec

Executes the Insert action in the specified Oracle database.

As a dedicated component, it allows gains in performance during Insert operations to an Oracle database.

The tOracleOutputBulk and tOracleBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tOracleOutputBulkExec component.

**tOracleOutputBulkExec Standard properties**

These properties are used to configure tOracleOutputBulkExec running in the Standard Job framework.

The Standard tOracleOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th>Connection type</th>

<table>
<thead>
<tr>
<th>Username and Password</th>
<th>DB user authentication data.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Table</th>
<th>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Action on table</th>
<th>On the table defined, you can perform one of the following operations:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>None</strong></td>
<td>No operations is carried out.</td>
</tr>
</tbody>
</table>

2710
Drop and create table: The table is removed and created again.

Create table: The table does not exist and gets created.

Create table if not exists: The table is created if does not exist.

Drop table if exists and create: The table is removed if it already exists and created again.

Clear table: The table content is deleted.

Truncate table: The table content is deleted. You do not have the possibility to rollback the operation.

File Name
Name of the file to be generated and loaded.

Warning:
This file is generated on the machine specified by the URI in the Host field so it should be on the same machine as the database server.

Create directory if not exists
This check box is selected by default. It creates a directory to hold the output table if required.

Append
Select this check box to add the new rows at the end of the file.

Action on data
On the data of the table defined, you can perform:

Insert: Insert data to an empty table. If the table already contains data, the Job stops and the existing data remains in the table.

Update: Update the existing data. You have to set the key on the schema if this option is selected.

Append: Append data to the table, whether the table is empty or not.

Replace: if the table already contains data, delete all the existing data and insert the new data. If the table is empty, insert the new data.

Truncate: If the table already contains data, truncate all the existing data and insert the new data. If the table is empty, insert the new data.

Schema and Edit Schema
A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- View schema: choose this option to view the schema only.
- Change to built-in property: choose this option to change the schema to Built-in for local changes.
- Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon
Built-In: You create and store the schema locally for this component only.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Field separator
Character, string or regular expression to separate fields.

Advanced settings

Advanced separator (for number)
Select this check box to change data separators for numbers:

**Thousands separator**: define separators you want to use for thousands.

**Decimal separator**: define separators you want to use for decimals.

Use existing control file
Select this check box and browse to the .ctl control file you want to use.

Field separator
Character, string or regular expression to separate fields.

Row separator
String (ex: \n on Unix) to separate rows.

Specify .ctl file’s INTO TABLE clause manually
Select this check box to enter manually the INTO TABLE clause of the control file directly into the code.

Use schema’s Date Pattern to load Date field
Select this check box to use the date model indicated in the schema for dates.

Specify field condition
Select this check box to define a condition for loading data.

Preserve blanks
Select this check box to preserve blank spaces.

Trailing null columns
Select this check box to load data with all empty columns.

Load options
Click + to add data loading options:

**Parameter**: select a loading parameter from the list.

**Value**: enter a value for the parameter selected.

NLS Language
From the drop-down list, select the language for your data if the data is not in Unicode.

Set Parameter NLS_TERRITORY
Select this check box to modify the conventions used for date and time formats. The default value is that of the operating system.
### Encoding
Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling.

### Oracle encoding type
Select the Oracle-specific encoding type for the data to be processed. This encoding type allows *tOracleOutputBulkExec* to properly generate the Sybase Bulk command.

### Output
Select the type of output for the standard output of the Oracle database:
- to console,
- to global variable.

### Convert columns and table names to uppercase
Select this check box to put columns and table names in upper case.

### Bulk file parameters
Set the parameters **Buffer Size** and **StringBuilder Size** for a performance gain according to the memory size.

### tStatCatcher Statistics
Select this check box to gather the job processing metadata at a job level as well as at each component level.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide. |

| Limitation | The database server/client must be installed on the same machine where the Studio is installed or where the Job using *tOracleOutputBulkExec* is deployed, so that the component functions properly. |
Related scenarios

For use cases in relation with **tOracleOutputBulkExec**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tOracleRollback

Cancels the transaction commit in the connected Oracle database to avoid committing part of a transaction involuntarily.

tOracleRollback Standard properties

These properties are used to configure tOracleRollback running in the Standard Job framework. The Standard tOracleRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tOracle* components, especially with the tOracleConnection and tOracleCommit components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection |
Related scenario

For **tOracleRollback** related scenario, see **tMysqlRollback** on page 2491.
tOracleRow

Executes the stated SQL query on the specified Oracle database.

Depending on the nature of the query and the database, tOracleRow acts on the actual DB structure or on the data (although without handling data). The SQLBuilder tool helps you write easily your SQL statements.

tOracleRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tOracleRow Standard properties**

These properties are used to configure tOracleRow running in the Standard Job framework.

The Standard tOracleRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
| Connection type | Drop-down list of available drivers:  
**Oracle OCI**: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.  
**Oracle Service Name**: Select this connection type to use the TNS alias that you give when you connect to the remote database.  
**Oracle SID**: Select this connection type to uniquely identify a particular database on a system.  
**Oracle Custom**: Select this connection type to access a clustered database. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>DB Version</td>
<td>Select the Oracle version in use.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| Query type     | Either Built-in or Repository.                                                                                     |
|                | **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.                      |

**Built-In**: You create and store the schema locally for this component only.  
**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
**Repository:** Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Use NB_LINE**

This option allows you to feed the variable with the number of rows inserted/updated/deleted to the next component or subjob. This field only applies if the query entered in **Query** field is an INSERT, UPDATE or DELETE query.

- **NONE:** does not feed the variable.
- **INSERTED:** feeds the variable with the number of rows inserted.
- **UPDATED:** feeds the variable with the number of rows updated.
- **DELETED:** feeds the variable with the number of rows deleted.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the **Talend Runtime** side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in **Talend Runtime**.

If you use the component’s own DB configuration, your data source connection will be closed at the end of the component. To prevent this from happening, use a shared DB connection with the data source alias specified.

This check box is not available when the **Use an existing connection** check box is selected.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link.

**Advanced settings**

**Propagate QUERY’s recordset**

Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.

**Note:**

This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**.

**Use PreparedStatement**

Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by "?" in the SQL instruction of the **Query field** in the **Basic Settings** tab.

**Parameter Index:** Enter the parameter position in the SQL instruction.
**Parameter Type:** Enter the parameter type.

**Parameter Value:** Enter the parameter value.

**Note:**
This option is very useful if you need to execute the same query several times. Performance levels are increased. You can also use PreparedStatement to avoid SQL injection. For a detailed scenario of utilizing this feature, see Using PreparedStatement objects to query data on page 2498.

---

**Commit every**
Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions.

**tStatCatcher Statistics**
Select this check box to collect log data at the component level.

---

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexiblility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an</td>
</tr>
</tbody>
</table>
environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenarios

For related topics, see:

- Combining two flows for selective output on page 2503
- Procedure on page 622.

| **Global Variables** | **NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.  
**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.  
**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as Output component. It requires an Input component and Row main link as input.</th>
</tr>
</thead>
</table>

### Dynamic settings

Click the `[+]` button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>This component does not support using SCD type 0 together with other SCD types.</th>
</tr>
</thead>
</table>

### Related scenario

For related scenarios, see tMysqlSCD on page 2508.
**tOracleSCDELT**

Reflects and tracks changes in a dedicated Oracle SCD table through SQL queries.

tOracleSCDELT addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated Oracle SCD table.

**tOracleSCDELT Standard properties**

These properties are used to configure tOracleSCDELT running in the Standard Job framework.

The Standard tOracleSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all [Talend products](https://www.talend.com/marketplace/download).

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see [Dynamic database components](https://www.talend.com/marketplace/download) on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply</strong>.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
</tbody>
</table>

**Built-in:** No property data stored centrally. Enter properties manually.

**Repository:** Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see [Talend Studio User Guide](https://www.talend.com/marketplace/download).
**Oracle OCI**: Select this connection type to use Oracle Call Interface with a set of C-language software APIs that provide an interface to the Oracle database.

**Oracle Service Name**: Select this connection type to use the TNS alias that you give when you connect to the remote database.

**Oracle SID**: Select this connection type to uniquely identify a particular database on a system.

**Oracle Custom**: Select this connection type to access a clustered database.

---

</tr>
<tr>
<td></td>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
</tbody>
</table>

**Schema and Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and
<table>
<thead>
<tr>
<th><strong>Surrogate Key</strong></th>

<tbody>
<tr>
<td><strong>Creation</strong></td>
<td>Select the method to be used for the surrogate key generation. For more information regarding the creation methods, see SCD management methodology on page 2511.</td>
</tr>
<tr>
<td><strong>Source Keys</strong></td>
<td>Select one or more columns to be used as keys, to ensure the unicity of incoming data.</td>
</tr>
<tr>
<td><strong>Source fields value include Null</strong></td>
<td>Select this check box to allow the source columns to have Null values. <strong>Note:</strong> The source columns here refer to the fields defined in the SCD type 1 fields and SCD type 2 fields tables.</td>
</tr>
<tr>
<td><strong>Use SCD Type 1 fields</strong></td>
<td>Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.</td>
</tr>
<tr>
<td><strong>Use SCD Type 2 fields</strong></td>
<td>Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes. <strong>Start date:</strong> Adds a column to your SCD schema to hold the start date value. You can select one of the input schema columns as Start Date in the SCD table. <strong>End Date:</strong> Adds a column to your SCD schema to hold the end date value for the record. When the record is currently active, the End Date column shows a null value, or you can select Fixed Year value and fill it in with a fictive year to avoid having a null value in the End Date field. <strong>Note:</strong> To avoid duplicated change records, it is recommended to select a column that can identify each change for this field. <strong>Log Active Status:</strong> Adds a column to your SCD schema to hold the true or false status value. This column helps to easily spot the active record. <strong>Log versions:</strong> Adds a column to your SCD schema to hold the version number of the record.</td>
</tr>
</tbody>
</table>

**Built-in:** The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. **Repository:** The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide.
Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC parameters</strong></th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</th>

</table>

Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is used as an output component. It requires an input component and Row main link as input.</th>
</tr>
</thead>
</table>
| **Dynamic settings** | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related Scenarios

For related scenarios, see:

- Tracking data changes in a Snowflake table using the `tJDBCSCDELT` component on page 1879.
- Tracking data changes in a PostgreSQL table using the `tPostgreSQLSCDELT` component on page 2948.
tOracleSP

Calls an Oracle database stored procedure.
tOracleSP offers a convenient way to centralize multiple or complex queries in a database and call them easily.

**tOracleSP Standard properties**

These properties are used to configure tOracleSP running in the Standard Job framework.
The Standard tOracleSP component belongs to the Databases family.
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>

<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td></td>
<td>Built-In: You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
<tr>
<td>SP Name</td>
<td>Type in the exact name of the Stored Procedure (or Function)</td>
</tr>
<tr>
<td>Is Function / Return result in</td>
<td>Select this check box, if the stored procedure is a function and one value only is to be returned.</td>
</tr>
<tr>
<td></td>
<td>Select on the list the schema column, the value to be returned is based on.</td>
</tr>
</tbody>
</table>
Click the Plus button and select the various Schema Columns that will be required by the procedures. Note that the SP schema can hold more columns than there are parameters used in the procedure.

Select the Type of parameter:
- **IN**: Input parameter.
- **OUT**: Output parameter/return value.
- **IN OUT**: Input parameter is to be returned as value, likely after modification through the procedure (function).
- **RECORDSET**: Input parameters is to be returned as a set of values, rather than single value.

**Note:**
Check Inserting data in mother/daughter tables on page 2426 if you want to analyze a set of records from a database table or DB query and return single records.

The Custom Type is used when a Schema Column you want to use is user-defined. Two Custom Type columns are available in the Parameters table. In the first Custom Type column:
- Select the check box in the Custom Type column when the corresponding Schema Column you want to use is of user-defined type.
- If all listed Schema Columns in the Parameters table are of custom type, you can select the check box before Custom Type once for them all.

Select a database type from the DB Type list to map the source database type to the target database type:
- **Auto-Mapping**: Map the source database type to the target database type automatically (default).
- **CLOB**: Character large object.
- **BLOB**: Binary large object.
- **DECIMAL**: Decimal numeric object.
- **NUMERIC**: Character 0 to 9.
- **XMLTYPE**: XML schema type.

**Warning:**
When mapping a column selected from the Return result in list box or set to the IN or OUT type of parameter to XMLTYPE, make sure that the column is of type String in the schema.

In the second Custom Type column, you can precise what the custom type is. The type may be:
- **STRUCT**: used for one element.
- **ARRAY**: used for a collection of elements.

In the Custom name column, specify the name of the custom type that you have given to this type.
Warning:
When an OUT parameter uses the custom type, make sure that its corresponding Schema Column has chosen the Object type in the schema table.

<table>
<thead>
<tr>
<th>Specify a data source alias</th>
<th>Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Additional JDBC parameters</th>
<th>Specify additional connection properties for the DB connection you are creating. This option is not available if you have selected the Use an existing connection check box in the Basic settings.</th>
</tr>
</thead>
<tbody>
<tr>
<td>NLS Language</td>
<td>In the list, select the language used for the data that are not used in Unicode.</td>
</tr>
<tr>
<td>NLS Territory</td>
<td>Select the conventions used for date and time formats. The default value is that of the operating system.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to gather the job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used as intermediary component. It can be used as start component but only input parameters are thus allowed.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Limitation**

The Stored Procedures syntax should match the Database syntax.
Checking number format using a stored procedure

The following job aims at connecting to an Oracle Database containing Social Security Numbers and their holders' name, calling a stored procedure that checks the SSN format of against a standard ###-###-#### format. Then the verification output results, 1 for valid format and 0 for wrong format get displayed onto the execution console.

• Drag and drop the following components from the Palette: tOracleConnection, tOracleInput, tOracleSP and tLogRow.
• Link the tOracleConnection to the tOracleInput using a Then Run connection as no data is handled here.
• And connect the other components using a Row Main link as rows are to be passed on as parameter to the SP component and to the console.
• In the tOracleConnection, define the details of connection to the relevant Database. You will then be able to reuse this information in all other DB-related components.
• Then select the tOracleInput and define its properties.

• Select the Use an existing connection check box and select the tOracleConnection component in the list in order to reuse the connection details that you already set.
• Select Repository as Property type as the Oracle schema is defined in the DB Oracle connection entry of the Repository. If you haven’t recorded the Oracle DB details in the Repository, then fill in the Schema name manually.
Then select **Repository** as **Schema**, and retrieve the relevant schema corresponding to your Oracle DB table.

<table>
<thead>
<tr>
<th>ID</th>
<th>NAME</th>
<th>CITY</th>
<th>SSNUMBER</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Jack</td>
<td>LA</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>2</td>
<td>Tom</td>
<td>NYC</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>3</td>
<td>Bill</td>
<td>SF</td>
<td>123-45-6789</td>
</tr>
<tr>
<td>4</td>
<td>Jana</td>
<td>NYC</td>
<td>236-52-2955</td>
</tr>
<tr>
<td>5</td>
<td>Brandon</td>
<td>SLC</td>
<td>561-52-B267</td>
</tr>
</tbody>
</table>

In this example, the SSN table has a four-column schema that includes *ID*, *NAME*, *CITY* and *SSNUMBER*.

In the **Query** field, type in the following Select query or select it in the list, if you stored it in the Repository.

```
select ID, NAME, CITY, SSNUMBER from SSN
```

Then select the **tOracleSP** and define its **Basic settings**.

- **Use an existing connection**
- **Schema**: *Repository*
- **SP Name**: "is_ssn"
- **Parameters**

<table>
<thead>
<tr>
<th>Scheme Column</th>
<th>Type</th>
<th>DBType</th>
<th>Custom Type</th>
<th>Custom Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>SSNUMBER</td>
<td>IN</td>
<td>AUTO-MAPPING</td>
<td></td>
<td>STRUCT</td>
</tr>
</tbody>
</table>

- **Like for the tOracleInput component, select Repository in the Property type field and select the Use an existing connection check box, then select the relevant entries in the respective list.**
- **The schema used for the tOracleSP slightly differs from the input schema. Indeed, an extra column (SSN_Valid) is added to the Input schema. This column will hold the format validity status (1 or 0) produced by the procedure.**

In the **SP Name** field, type in the exact name of the stored procedure (or function) as called in the Database. In this use case, the stored procedure name is *is_ssn*. 
The basic function used in this particular example is as follows:

```sql
CREATE OR REPLACE FUNCTION is_ssn(string_in VARCHAR2)
RETURN PLS_INTEGER
IS
  -- validating ###-##-#### format
BEGIN
  IF TRANSLATE(string_in, '0123456789A', 'AAAAAAAAAAB') = 'AAA-AA-AAAA' THEN
    RETURN 1;
  END IF;
  RETURN 0;
END is_ssn;
/
```

As a return value is expected in this use case, the procedure acts as a function, so select the Is function check box.

The only return value expected is based on the ssn_valid column, hence select the relevant list entry.

In the Parameters area, define the input and output parameters used in the procedure. In this use case, only the SSNumber column from the schema is used in the procedure.

Click the plus sign to add a line to the table and select the relevant column (SSNumber) and type (IN).

Then select the tLogRow component and click Sync Column to make sure the schema is passed on from the preceding tOracleSP component.

Select the Print values in cells of a table check box to facilitate the output reading.

Then save your job and press F6 to run it.

On the console, you can read the output results. All input schema columns are displayed even though they are not used as parameters in the stored procedure.

The final column shows the expected return value, whether the SS Number checked is valid or not.

Note:

Check Inserting data in mother/daughter tables on page 2426 if you want to analyze a set of records from a database table or DB query and return single records.
Related scenarios

For related scenarios, see:

- Retrieving personal information using a stored procedure on page 2404.
- Using tMysqlSP to find a State Label using a stored procedure on page 2528.
- Executing a stored procedure using tMDMSP on page 2180.
**tOracleTableList**

Lists the names of specified Oracle tables using a SELECT statement based on a WHERE clause. 
tOracleTableList iterates on a set of tables through a defined Oracle connection.

**tOracleTableList Standard properties**

These properties are used to configure tOracleTableList running in the Standard Job framework. 
The Standard tOracleTableList component belongs to the Databases family. 
The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tOracleConnection component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td>Where clause for table name selection</td>
<td>Enter the WHERE clause that will be used to identify the tables to iterate on.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Global Variables**

- **CURRENT_TABLE**: the name of the table currently iterated upon. This is a Flow variable and it returns a string.
- **NB_TABLE**: the number of tables iterated upon so far. This is a Flow variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

**View schema**: choose this option to view the schema only.
**Change to built-in property**: choose this option to change the schema to Built-in for local changes.
**Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

Define the elements to be checked in the table provided.
- **Column**: shows the column(s) from the input schema. It is completed automatically once a schema is retrieved or created.
- **Element type**: select the element type for the input column. Only one column can be defined as Measure.
- **Default**: type in the default value to be used if you have selected the Use default option in the On element error field.

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data on the component level.</th>
</tr>
</thead>
</table>

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

### Usage

| Usage rule | This component requires an input component. |
### Connections

Outgoing links (from this component to another):
- **Row**: Main; Rejects
- **Trigger**: Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Main; Rejects

For further information regarding connections, see [Talend Studio User Guide](https://help.talend.com).

### Limitation

This component only works on **Normal** Palo cubes.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in [Talend Help Center](https://help.talend.com).

### Related scenario

For a related scenario, see *Rejecting inflow data when the elements to be written do not exist in a given cube* on page 2790.
tPaloClose

Closes an active connection to a Palo Server.
This component is used to disconnect a connection to a Palo server to release occupied resources.

**tPaloClose Standard properties**

These properties are used to configure tPaloClose running in the Standard Job framework.
The Standard tPaloClose component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

| Component List | Select a tPaloConnection component from the drop-down list if more than one connection is planned for the current Job. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is more commonly used with other Palo components, especially tPaloConnection. |

| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for |
example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tPaloConnection

Opens a connection to a Palo Server and allows other components involved in a process to share the connection for the duration of the process.

### Related scenario

For related scenarios, see *Creating a dimension with elements* on page 2766.
tPaloCube

Performs operations on a given Palo cube.
This component creates, deletes or clears Palo cubes from existing dimensions in a Palo database.

**tPaloCube Standard properties**

These properties are used to configure tPaloCube running in the Standard Job framework.
The Standard tPaloCube component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level. |
| Host Name | Enter the host name or the IP address of the host server. |
| Server Port | Type in the listening port number of the Palo server. |
| Username and Password | Enter the Palo user authentication data.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| Database | Type in the name of the database in which the operation is to take place. |
| Cube | Type in the name of the cube where the operation is to take place. |
| Cube type | From the drop-down list, select the type of cube on which the operation is to be carried out:
- **Normal**: this is the normal and default type of cube.
- **Attribute**: an Attribute cube is created with a normal cube.
- **User Info**: User Info cubes can be created/modified with this component. |
| Action on cube | Select the operation you want to carry out on the cube defined:
- **Create cube**: the cube does not exist and will be created.
- **Create cube if not exists**: the cube is created if it does not exist.
- **Delete cube if exists and create**: the cube is deleted if it already exists and a new one will be created.
- **Delete cube**: the cube is deleted from the database. |
- **Clear cube**: the data is cleared from the cube.

**Dimension list**

Add rows and enter the name of existing database dimension's to be used in the cube. The order of the dimensions in the list determines the order of the dimensions created.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | CUBENAME: the name of the cube. This is an After variable and it returns a string.  
ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

**Usage**

| Usage rule | Can be used as a standalone component for dynamic cube creation with a defined dimension list. |

**Connections**

Outgoing links (from this component to another):  
**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):  
**Row**: Iterate  
**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see [Talend Studio User Guide](#).

**Limitation**

The cube creation process does not create dimensions from scratch, so the dimensions to be used in the cube must be created beforehand.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can
Creating a cube in an existing database

The Job in this scenario creates a new two dimensional cube in the Palo demo database *Biker*.

To replicate this scenario, proceed as follows:

**Configuring the tPaloCube component**

**Procedure**

1. Drop **tPaloCube** from the **Palette** onto the design workspace.
2. Double-click **tPaloCube** to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.
4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

6. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

7. In the **Cube** field, type in the name you want to use for the cube to be created, for example, *bikerTalend*.

8. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

9. In the **Action on cube** field, select the action to be performed. In this scenario, select *Create cube*.

10. Under the **Dimension list** table, click the plus button twice to add two rows into the table.

11. In the **Dimension list** table, type in the name for each newly added row to replace the default row name. In this scenario, type in *Months* for the first row and *Products* for the second. These two dimensions exist already in the Biker database where the new cube will be created.

### Job execution

Press **F6** to run the Job.

A new cube has been created in the *Biker* database and the two dimensions are added into this cube.
tPaloCubeList

Retrieves a list of cube details from the given Palo database.

This component lists cube names, cube types, number of assigned dimensions, the number of filled cells from the given database.

Discovering the read-only output schema of tPaloCubeList

The below table presents information related to the read-only schema of the tPaloCubeList component.

<table>
<thead>
<tr>
<th>Column</th>
<th>Type</th>
<th>Description</th>

<td>Type in the name of the database whose cube details you want to retrieve.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_CUBES**: the number of cubes. This is an After variable and it returns an integer.  
**CUBEID**: the ID of the cube. This is a Flow variable and it returns an integer.  
**CUBENAME**: the name of the cube. This is a Flow variable and it returns a string.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see [Talend Studio User Guide](#). |

**Usage**

| **Usage rule** | This component can be used as a start component. It requires an output component. |
| **Connections** | Outgoing links (from this component to another):  
**Row**: Main, Iterate;  
**Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |
## Limitation

The output schema is fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Retrieving detailed cube information from a given database

The Job in this scenario retrieves detailed information of the cubes pertaining to the demo Palo database, **Biker**.

![Diagram](https://via.placeholder.com/150)

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop **tPaloCubeList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloCubeList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

**Configuring the tPaloCube component**

**Procedure**

1. Double-click the **tPaloCube** component to open its **Component** view.
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name in which you want to create the cube, *Biker* in this example.

**Job execution**

Press **F6** to run the Job.

The cube details are retrieved from the *Biker* database and are listed in the console of the **Run** view.

```plaintext
[statistics] connected
26|Orders|8|4529|1236|30400|133005|1|0
27|biker|Talent|2|1830|3|1|0

Creating a database

The Job in this scenario creates a new database on a given Palo server.
To replicate this scenario, proceed as follows:

**Procedure**

1. Drop **tPaloDatabase** from the component **Palette** onto the design workspace.
2. Double-click the **tPaloDatabase** component to open its **Component** view.

3. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

4. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is *7777*.

5. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

6. In the **Database** field, type in the database name in which you want to create the cube, *talendDatabase* in this example.

7. In the **Action on database** field, select the action to be performed. In this scenario, select **Create database** as the database to be created does not exist.

8. Press **F6** to run the Job.

**Results**

A new database is created on the given Palo server.
tPaloDatabaseList

Lists database names, database types, number of cubes, number of dimensions, database status and database id from a given Palo server.

The tPaloDatabaseList retrieves a list of database details from the given Palo server.

**Discovering the read-only output schema of tPaloDatabaseList**

The below table presents information related to the read-only output schema of the tPaloDatabaseList component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database_id</td>

For further information regarding connections, see [Talend Studio User Guide](#).
Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Retrieving detailed database information from a given Palo server

The Job in this scenario retrieves details of all of the databases from a given Palo server.

To replicate this scenario, proceed as follows:

Setting up the Job

Procedure

1. Drop tPaloDatabaseList and tLogRow from the component Palette onto the design workspace.
2. Right-click tPaloDatabaseList to open the contextual menu.
3. From this menu, select Row > Main to link the two components.

Configuring the tPaloDatabaseList component

Procedure

1. Double-click the tPaloDatabaseList component to open its Component view.
2. In the Host name field, type in the host name or the IP address of the host server, localhost for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

**Job execution**

Press **F6** to run the Job.

Details of all of the databases in the Palo server are retrieved and listed in the console of the Run view.

<p>| | | | |</p>
<table>
<thead>

</table>

For further information about the output schema, see *Discovering the read-only output schema of tPaloDatabaseList* on page 2759.
tPaloDimension

Manages Palo dimensions, even elements inside a database.

The tPaloDimension creates, drops or recreates dimensions with or without dimension elements inside a Palo database.

**tPaloDimension Standard properties**

These properties are used to configure tPaloDimension running in the Standard Job framework.

The Standard tPaloDimension component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use an existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>

</table>
Creating a dimension with elements

The Job in this scenario creates a date dimension with simple element hierarchy composed of three levels: Year, Month, Date.

To replicate this scenario, proceed as follows:

Setting up the Job

Procedure

1. Drop tPaloConnection, tRowGenerator, tMap, tPaloDimension from the component Palette onto the design workspace.
2. Right-click tPaloConnection to open the contextual menu and select Trigger > On Subjob Ok to link it to tRowGenerator.
3. Right-click tRowGenerator to open the contextual menu and select Row > Main to link it to tMap.

Note: tRowGenerator is used to generate rows at random in order to simplify this process. In the real case, you can use one of the other input components to load your actual data.

4. Right-click tMap to open the contextual menu and select Row > New output to link to tPaloDimension, then name it as out1 in the dialog box that pops up.

Setting up the DB connection

Procedure

1. Double-click the tPaloConnection component to open its Component view.
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are *admin*.

### Configuring the input component

**Procedure**

1. Double-click **tRowGenerator** to open its editor.

   ![tRowGenerator Editor](image)

   **Schema**
   
<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Functions</th>
<th>Environment</th>
</tr>
</thead>
<tbody>
<tr>
<td>random_date</td>
<td></td>
<td>Date</td>
<td>getRandomDate</td>
<td></td>
</tr>
</tbody>
</table>

   **Function parameters**
   
   return an ISO formatted random date

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Value</th>
<th>Comment</th>
</tr>
</thead>
<tbody>
<tr>
<td>min</td>
<td>&quot;2010-01-01&quot;</td>
<td>minimum date</td>
</tr>
<tr>
<td>max</td>
<td>&quot;2010-12-31&quot;</td>
<td>maximum date (superior to ...)</td>
</tr>
</tbody>
</table>

   ![Function Parameters](image)

   Click **OK** to validate your modifications and close the editor.

2. On the upper part of the editor, click the plus button to add one column and rename it as **random_date** in the **Column** column.

3. In the newly added row, select **Date** in the **Type** column and **getRandomDate** in the **Functions** column.

4. In the **Function parameters** view on the lower part of this editor, type in the new minimum date and maximum date values in the **Value** column. In this example, the minimum is *2010-01-01*, the maximum is *2010-12-31*.

5. Click **OK** to validate your modifications and close the editor.

6. On the dialog box that pops up, click **OK** to propagate your changes.

### Configuration in the tMap editor

**Procedure**

1. Double-click **tMap** to open its editor.
2. On the **Schema editor** view on the lower part of the **tMap** editor, under the **out1** table, click the plus button to add three rows.

3. In the **Column** column of the **out1** table, type in the new names for the three newly added rows. They are **Year**, **Month**, and **Date**. These rows are then added automatically into the **out1** table on the upper part of the **tMap** editor.

4. In the **out1** table on the upper part of the **tMap** editor, click the **Expression** column in the **Year** row to locate the cursor.

5. Press **Ctrl+space** to open the drop-down variable list.

6. Double-click **TalendDate.formatDate** to select it from the list. The expression to get the date displays in the **Year** row under the **Expression** column. The expression is `TalendDate.formatDate("yyyy-MM-dd HH:mm:ss",myDate)`.

7. Replace the default expression with `TalendDate.formatDate("yyyy", row1.random_date)`.

8. Do the same for the **Month** row and the **Date** row to add this default expression and to replace it with `TalendDate.formatDate("MM", row1.random_date)` for the **Month** row and with `TalendDate.formatDate("dd-MM-yyyy", row1.random_date)` for the **Date** row.

9. Click **OK** to validate this modification and accept the propagation by clicking **OK** in the dialog box that pops up.

**Configuring the tPaloDimension component**

**Procedure**

1. On the workspace, double-click **tPaloDimension** to open its **Component** view.
2. Select the **Use an existing connection** check box. Then **tPaloConnection_1** displays automatically in the **Connection configuration** field.

3. In the **Database** field, type in the database in which the new dimension is created, **talendDatabase** for this scenario.

4. In the **Dimension** field, type in the name you want to use for the dimension to be created, for example, **Date**.

5. In the **Action on dimension** field, select the action to be performed. In this scenario, select **Create dimension if not exist**.

6. Select the **Create dimension elements** check box.

7. In the **Consolidation Type** area, select the **Normal** check box.

8. Under the element hierarchy table in the **Consolidation Type** area, click the plus button to add three rows into the table.

9. In the **Input column** column of the element hierarchy table, select **Year** from the drop-down list for the first row, **Month** for the second and **Date** for the third. This determinates levels of elements from different columns of the input schema.

**Job execution**

Press **F6** to run the Job.

A new dimension is then created in your Palo database **talendDatabase**.
tPaloDimensionList

Retrieves a list of dimension details from the given Palo database.

tPaloDimensionList lists dimension names, dimension types, number of dimension elements, maximum dimension indent, maximum dimension depth, maximum dimension level, dimension id from a given Palo server.

Discovering the read-only output schema of tPaloDimensionList

The below table presents information related to the read-only output schema of the tPaloDimensionList component.

<table>
<thead>
<tr>
<th>Database</th>
<th>Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dimension_id</td>
<td>long</td>
<td>Internal ID of the dimension.</td>
</tr>
<tr>

<tr>
<td>Dimension_max_depth</td>
<td>int</td>
<td>Maximum depth of the dimension</td>
</tr>
<tr>
<td>Dimension_type</td>
<td>int</td>
<td>Type of the dimension.</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 0 =normal</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 1 =system</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 2 =attribute</td>
</tr>
<tr>
<td></td>
<td></td>
<td>- 3 =user info</td>
</tr>
</tbody>
</table>

tPaloDimensionList Standard properties

These properties are used to configure tPaloDimensionList running in the Standard Job framework.
The Standard tPaloDimensionList component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |
| **Host Name** | Enter the host name or the IP address of the host server. |
| **Server Port** | Type in the listening port number of the Palo server. |
| **Username and Password** | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Database** | The name of the database where the dimensions of interest reside. |
| **Retrieve cube dimensions** | Select this check box to retrieve dimension information from an existing cube. |
| **Cube** | Type in the name of the cube from which dimension information is retrieved. **Note:** Available when you select the Retrieve cube dimensions check box. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
  - Built-in: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide.  
  - Repository: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **Advanced settings** |  
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |
### Global Variables

<table>
<thead>
<tr>

### Retrieving detailed dimension information from a given database

The Job in this scenario retrieves details of all of the dimensions from a given database.
To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop `tPaloDimensionList` and `tLogRow` from the component `Palette` onto the design workspace.
2. Right-click `tPaloDimensionList` to open the contextual menu.
3. From this menu, select `Row > Main` to link the two components.

**Configuring the tPaloDimensionList component**

**Procedure**

1. Double-click the `tPaloDimensionList` component to open its `Component` view.

2. In the **Host name** field, type in the host name or the IP address of the host server, `localhost` for this example.
3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is `7777`.
4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.
5. In the **Database** field, type in the database name where the dimensions of interest reside, `Biker` in this example.

**Job execution**

Press **F6** to run the Job.

Details of all the dimensions in the `Biker` database are retrieved and listed in the console of the `Run` view.
For further information about the output schema, see Discovering the read-only output schema of tPaloDimensionList on page 2771.
tPaloInputMulti

Retrieves the stored or calculated values in combination with the element records out of a cube.
The tPaloInputMulti retrieves data (elements as well as values) from a Palo cube.

**tPaloInputMulti Standard properties**

These properties are used to configure tPaloInputMulti running in the Standard Job framework.
The Standard tPaloInputMulti component belongs to the Business Intelligence family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>

<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database where the elements of interest reside.</td>
</tr>
<tr>
<td>Cube</td>
<td>Type in the name of the cube where the dimension elements to be retrieved are stored.</td>
</tr>
</tbody>
</table>
| Cube type                 | Select the cube type from the drop-down list for the cube of concern. This type may be:  
  - Normal  
  - Attribut  
  - System  
  - User Info |
| Commit size               | Type in the row count of each batch to be retrieved. |
| Schema and Edit Schema    | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available: |
• **View schema**: choose this option to view the schema only.
• **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

| Built-in: | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository: | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |

**Cube Query**

Complete this table with the query you want to use to retrieve data. The columns to be filled are:

- **Column**: the schema columns are added automatically to this column once defined in the schema editor. The schema columns are used to store the retrieved dimension elements.
- **Dimensions**: type in each of the dimension names of the cube from which you want to retrieve dimension elements.
- **Elements**: type in the dimension elements from which data is retrieved. If several elements are needed from one single dimension, separate them with a comma.

**Warning:**
The dimension order listed in this column must be consistent with the order given in the cube that stores these dimensions.

**Advanced settings**

- **tStat Catcher Statistics**: Select this check box to collect log data at the component level.

**Global Variables**

- **Global Variables**: **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an output component.</th>
</tr>
</thead>
</table>

Connections

Outgoing links (from this component to another):
- **Row**: Main
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Iterate
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see Talend Studio User Guide.

Limitation

According to the architecture of OLAP-Systems only one single value (text or numeric) could be retrieved from the cube. The MEASURE column and the TEXT column are fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Retrieving dimension elements from a given cube

The Job in this scenario retrieves several dimension elements from a demo Palo cube Sales.

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop **tPalInputMulti** and **tLogRow** from the component Palette onto the design workspace.
2. Right-click **tPalInputMulti** to open its contextual menu.
3. In the menu, select **Row > Main** to connect **tPaloInputMulti** to **tLogRow** with a **row** link.

**Setting up the DB connection**

**Procedure**

1. Double-click the **tPaloInputMulti** component to open its **Component** view.

   ![tPaloInputMulti Component View]

2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are **admin**.

**Configuring the Cube Query**

**Procedure**

1. In the **Database** field, type in the database name in which the cube to be used is stored.

2. In the **Cube** field, type in the cube name in which the dimensions of interests are stored. In this scenario, it is one of the demo cubes **Sales**.

3. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

4. Next to the **Edit schema** field, click the three-dot button to open the schema editor.
5. In the schema editor, click the plus button to add the rows of the schema to be edited. In this example, add rows corresponding to all of the dimensions stored in the Sales cube: Products, Regions, Months, Years, Datatypes, Measures. Type in them in the order given in this cube.

6. Click OK to validate this editing and accept the propagation of this change to the next component. Then these columns are added automatically into the Column column of the Cube query table in the Component view. If the order is not consistent with the one in the Sales cube, adapt it using the up and down arrows under the schema table.

7. In the Dimensions column of the Cube query table, type in each of the dimension names stored in the Sales cube regarding to each row in the Column column. In the Sales cube, the dimension names are: Products, Regions, Months, Years, Datatypes, Measures.

8. In the Elements columns of the Cube query table, type in the dimension elements you want to retrieve regarding to the dimensions they belong to. In this example, the elements to be retrieved are All Products, Germany and Austria (Belonging to the same dimension Regions, these two elements are entered in the same row and separated with a comma), Jan, 2009, Actual, Turnover.

Job execution

Procedure

1. Click tLogRow to open its Component view.

2. In the Mode area, select the Table (print values in cells of a table) check box to display the execution result in a table.
3. Press **F6** to run the Job.

Results

The dimension elements and the corresponding Measure values display in the **Run** console.

tPaloOutput

Takes the input stream and writes it to a given Palo cube.
The tPaloOutput writes one row of data (elements as well as values) into a Palo cube.

**tPaloOutput Standard properties**

These properties are used to configure tPaloOutput running in the Standard Job framework. The Standard tPaloOutput component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined. Note that when a Job contains the parent Job and the child Job, <strong>Component List</strong> presents only the connection components in the same Job level.</td>
</tr>
<tr>
<td>Host Name</td>
<td>Enter the host name or the IP address of the host server.</td>
</tr>
<tr>
<td>Server Port</td>
<td>Type in the listening port number of the Palo server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>

</tr>
<tr>
<td><strong>Commit size</strong></td>
<td>Type in the row count of each batch to be written into the cube.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
</tbody>
</table>
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Built-in:</th>
<th>The schema is created and stored locally for this component only. Related topic: see <a href="#">Talend Studio User Guide</a>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository:</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <a href="#">Talend Studio User Guide</a>.</td>
</tr>
</tbody>
</table>

**Measure value**

Select the column from the input stream which holds the Measure or Text values.

**Splash mode**

Select the splash mode used to write data into a consolidated element. The mode may be:

- **Add**: it writes values to the underlying elements.
- **Default**: it uses the default splash mode.
- **Set**: it simply sets or replaces the current value and make the distribution based on the other values.
- **Disable**: it applies no splashing.

For further information about the Palo splash modes, see Palo’s user guide.

<table>
<thead>
<tr>
<th>Add values</th>
<th>Select this check box to add new values to the current values for a sum. Otherwise these new values will overwrite the current ones.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use eventprocessor</td>
<td>Select this check box to call the supervision server.</td>
</tr>
</tbody>
</table>

**Die on error**

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an input component.</th>
</tr>
</thead>
</table>

| Connections | Outgoing links (from this component to another):
Row: Main
Trigger: Run if; On Component Ok; On Component Error. |

Incoming links (from one component to this one):
Row: Main; Reject

For further information regarding connections, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Limitation</th>
<th>Numeric measures are only be accepted as Double or String type. When the string type is used, write the value to be processed between quotation marks.</th>
</tr>
</thead>
</table>

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Writing data into a given cube

The Job in this scenario writes new values in the Sales cube given as demo in the Demo database installed with Palo.

To replicate this scenario, proceed as follows:
Setting up the Job

Procedure
1. Drop tFixedFlowInput and tPaloOutputMulti from the component Palette onto the design workspace.
2. Right-click tFixedFlowInput to open its contextual menu.
3. In this menu, select Row > Main to connect this component to tPaloOutputMulti.

Configuring the input component

Procedure
1. Double-click the tFixedFlowInput component to open its Component view.

   ![Component view](image)

   - **Basic settings**
     - **Advanced settings**
     - **Dynamic settings**
     - **View**
     - **Documentation**

   **Schema**
   - Schema: Built-In
   - Edit schema
   - Number of rows: 1
   - Mode
     - Use Single Table

   **Values**
   - Products: "Desktop L"
   - Regions: "Germany"
   - Months: "Jan"
   - Years: "2009"
   - Datatypes: "Actual"
   - Measures: "Turnover"
   - Value: 1,234.56

   - Use Inline Table
   - Use Inline Content (delimited file)

2. Click the three-dot button to open the schema editor.
3. In the schema editor, click the plus button to add 7 rows and rename them respectively as Products, Regions, Months, Years, Datatypes, Measures and Values. The order of these rows must be consistent with that of the corresponding dimensions in the Sales cube and the type of the Value column where the measure value resides is set to double/Double.

4. Click OK to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the Value table under the Use single table check box, in the Mode area.

5. In the Value table, type in values for each row in the Value column. In this example, these values are: Desktop L, Germany, Jan, 2009, Actual, Turnover, 1234.56.

**Configuring the output component**

**Procedure**

1. Double-click tPaloOutputMulti to open its Component view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are **admin**.

4. In the **Database** field, type in the database name in which you want to create the cube, **Demo** in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, **Sales**.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select **Value**.

**Job execution**

Press **F6** to run the Job.

The inflow data has been written into the **Sales** cube.

---

**Rejecting inflow data when the elements to be written do not exist in a given cube**

The Job in this scenario tries to write data into the **Sales** cube but as the elements of interest do not exist in this cube, the inflow data is rejected.

To replicate this scenario, proceed as follows:
Setting up the Job

Procedure
1. Drop `tFixedFlowInput`, `tPaloCheckElements`, `tPaloOutputMulti` and `tLogRow` from the component Palette onto the design workspace.
2. Right-click `tFixedFlowInput` to open its contextual menu.
3. In this menu, select Row > Main to connect this component to `tPaloCheckElements`.
4. Do the same to connect `tPaloOutputMulti` using row link.
5. Right-click `tPaloCheckElements` to open its contextual menu.
6. In this menu, select Row > Reject to connect this component to `tLogRow`.

Configuring the input component

Procedure
1. Double-click the `tFixedFlowInput` component to open its Component view.
2. Click the three-dot button to open the schema editor.

<table>
<thead>
<tr>
<th>Column</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Products</td>
<td>&quot;Desktop L&quot;</td>
</tr>
<tr>
<td>Regions</td>
<td>&quot;Germany&quot;</td>
</tr>
<tr>
<td>Months</td>
<td>&quot;Jan&quot;</td>
</tr>
<tr>
<td>Years</td>
<td>&quot;2009&quot;</td>
</tr>
<tr>
<td>Datatypes</td>
<td>&quot;Actual&quot;</td>
</tr>
<tr>
<td>Measures</td>
<td>&quot;Turnover&quot;</td>
</tr>
<tr>
<td>Value</td>
<td>123456</td>
</tr>
</tbody>
</table>
In the schema editor, click the plus button to add 7 rows and rename them respectively as Products, Regions, Months, Years, Datatypes, Measures and Values. The order of these rows must be consistent with that of the corresponding dimensions in the Sales cube and the type of the Value column where the measure value resides is set to double/Double.

Click OK to validate the editing and accept the propagation prompted by the dialog box that pops up. Then the schema column labels display automatically in the Value table under the Use single table check box, in the Mode area.

In the Value table, type in values for each row in the Value column. In this example, these values are: Smart Products, Germany, Jan, 2009, Actual, Turnover, 1234.56. The Smart Products element does not exist in the Sales cube.

Configuring the tPaloCheckElements component

Procedure

1. Double-click tPaloCheckElements to open its Component view.
2. In the **Host name** field, type in `localhost`.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is `7777`.

4. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are `admin`.

5. In the **Database** field, type in the database name in which you want to create the cube, `Demo` in this example.

6. In the **Cube** field, type in the name of the cube you want to write data in, for example, `Sales`.

7. In the **On Element error** field, select **Reject row** from the drop-down list.

8. In the element table at the bottom of the **Basic settings** view, click the **Element type** column in the **Value** row and select **Measure** from the drop down list.

**Configuring the output component**

**Procedure**

1. Double-click `tPaloOutputMulti` to open its **Component** view.
2. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is **7777**.

3. In the **Username** field and the **Password** field, type in the authentication information. In this example, both of them are **admin**.

4. In the **Database** field, type in the database name in which you want to create the cube, **Demo** in this example.

5. In the **Cube** field, type in the name of the cube you want to write data in, for example, **Sales**.

6. In the **Cube type** field, select the **Normal** type from the drop-down list for the cube to be created, meaning this cube will be normal and default.

7. In the **Measure Value** field, select the Measure element. In this scenario, select **Value**.

### Job execution

Press **F6** to run the Job.

The data to be written is rejected and displayed in the console of the **Run** view. You can read that the error message is **Smart Products**.

```text
[statistics] connecting to socket on port 3407
[statistics] connected
| tLogRow_1
| Products | Regions | Months | Years | Datatypes | Measures | Value | errorMessage
|----------|---------|--------|-------|-----------|---------|-------|----------------|
| Smart Products | Germany | Jan | 2009 | Actual | Turnover | 1234.56 | Products: Smart Products
[statistics] disconnected
Job JobOutputExistingElements ended at 14:45 09/11/2010. [exit code=0]
```
tPaloRule

Manages rules in a given cube.

The tPaloRule creates or modifies rules in a given cube.

tPaloRule Standard properties

These properties are used to configure tPaloRule running in the Standard Job framework.

The Standard tPaloRule component belongs to the Business Intelligence family.

The component in this framework is available in all Talend products.

Basic settings

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.
| Host Name | Enter the host name or the IP address of the host server.
| Server Port | Type in the listening port number of the Palo server.
| Username and Password | Enter the Palo user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.
| Database | Type in the name of the database where the dimensions applying the rules of interest reside.
| Cube | Type in the name of the cube whose dimension information is retrieved.
| Cube rules | Complete this table to perform various actions on specific rules.
| Definition | type in the rule to be applied.
| External Id | type in the user-defined external ID.
| Comment | type in comment for this rule.
| Activated | select this check box to activate this rule.
| Action | select the action to be performed from the drop-down list.
| - Create | create this rule.
| - Delete | delete this rule.
| - Update | update this rule. |
Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | This component can be used in standalone for rule creation, deletion or update. |

Connections

| Outgoing links (from this component to another): Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |

| Incoming links (from one component to this one): Row: Iterate Trigger: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error. |

For further information regarding connections, see Talend Studio User Guide.

Limitation

| Update or deletion of a rule is available only when this rule has been created with external ID. Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Creating a rule in a given cube

The Job in this scenario creates a rule applied on dimensions of a given cube.
To replicate this scenario, proceed as follows:

**Setting up the DB connection**

**Procedure**

1. Drop tPaloRule from the component Palette onto the design workspace.
2. Double-click the tPaloRule component to open its Component view.

3. In the Host name field, type in the host name or the IP address of the host server, `localhost` for this example.
4. In the Server Port field, type in the listening port number of the Palo server. In this scenario, it is 7777.
5. In the Username field and the Password field, type in the authentication information. In this example, both of them are `admin`.
6. In the Database field, type in the database name in which the dimensions applying the created rules reside, `Biker` in this example.
7. In the Cube field, type in the name of the cube which the dimensions applying the created rules belong to, for example, `Orders`. 
Setting the Cube rules

Procedure

1. Under the Cube rules table, click the plus button to add a new row.
2. In the Cube rules table, type in "['2009'] = 123" in the Definition column, OrderRule1 in the External Id column and Palo Demo Rules in the Comment column.
3. In the Activated column, select the check box.
4. In the Action column, select Create from the drop-down list.

Job execution

Press F6 to run the Job.

The new rule has been created and the value of every 2009 element is 123.

<table>
<thead>
<tr>
<th></th>
<th>A</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>localhost/Biker</td>
</tr>
<tr>
<td>2</td>

<td>The formula of this rule. For further information about this formula, see the Palo user guide.</td>
</tr>
<tr>
<td>rule_extern_id</td>
<td>string</td>
<td>The user-defined external id.</td>
</tr>
<tr>
<td>rule_comment</td>
<td>string</td>
<td>The user-edited comment on this rule.</td>
</tr>
<tr>
<td>rule_activated</td>
<td>boolean</td>
<td>Indicates if this rule had been activated or not.</td>
</tr>
</tbody>
</table>

tPaloRuleList Standard properties

These properties are used to configure tPaloRuleList running in the Standard Job framework. The Standard tPaloRuleList component belongs to the Business Intelligence family. The component in this framework is available in all Talend products.

Basic settings

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

Enter the host name or the IP address of the host server.

Type in the listening port number of the Palo server.

Enter the Palo user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

The name of the database where the cube of interest resides.
<table>
<thead>
<tr>
<th>Cube</th>
<th>Type in the name of the cube in which you want to retrieve the rule information.</th>
</tr>
</thead>
</table>

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Built-in</th>
<th>The schema is created and stored locally for this component only. Related topic: see <em>Talend Studio User Guide</em>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Repository</td>
<td>The schema already exists and is stored in the Repository, hence can be reused. Related topic: see <em>Talend Studio User Guide</em>.</td>
</tr>
</tbody>
</table>

### Advanced settings

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Global Variables

**Global Variables**

- **NB_RULES**: the number of rules. This is an After variable and it returns an integer.
- **EXTERNAL_RULEID**: the external ID of the rule. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*. |
Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used in standalone or as start component of a process.</th>
</tr>
</thead>
</table>

Connections

Outgoing links (from this component to another):
- **Row**: Main; Iterate.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Iterate
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On Component Ok; On Component Error.

For further information regarding connections, see *Talend Studio User Guide*.

Limitation

The output schema is fixed and read-only.

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Retrieving detailed rule information from a given cube

The Job in this scenario retrieves rule details applied on the dimensions of a given cube.

To replicate this scenario, proceed as follows:

**Setting up the Job**

**Procedure**

1. Drop **tPaloRuleList** and **tLogRow** from the component **Palette** onto the design workspace.
2. Right-click **tPaloRuleList** to open the contextual menu.
3. From this menu, select **Row > Main** to link the two components.

**Configuring the tPaloRuleList component**

**Procedure**

1. Double-click the **tPaloRuleList** component to open its **Component** view.
2. In the **Host name** field, type in the host name or the IP address of the host server, *localhost* for this example.

3. In the **Server Port** field, type in the listening port number of the Palo server. In this scenario, it is 7777.

4. In the **Username** and **Password** fields, type in the authentication information. In this example, both of them are *admin*.

5. In the **Database** field, type in the database name where the dimensions applying the rules of interest reside, *Biker* in this example.

6. In the **Cube** field, type in the name of the cube which the rules of interest belong to.

### Job execution

Press F6 to run the Job.

Details of all of the rules in the *Orders* cube are retrieved and listed in the console of the Run view.

```
[statistics] connecting to socket on port 3743
[statistics] connected

<table>
<thead>
<tr>
<th>rule_identifier</th>
<th>rule_definition</th>
<th>ruleExternId</th>
<th>ruleComment</th>
<th>ruleActivated</th>
</tr>
</thead>
<tbody>
<tr>
<td>[]</td>
<td></td>
<td></td>
<td>[2009] = 123</td>
<td>OrderRule1</td>
</tr>
</tbody>
</table>

[statistics] disconnected
Job tPalo ended at 16:35 12/11/2010. [exit code=0]
```

For further information about the output schema, see Discovering the read-only output schema of tPaloRuleList on page 2799.
**tParAccelBulkExec**

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelBulkExec performs an Insert action on the data.

**tParAccelBulkExec Standard properties**

These properties are used to configure tParAccelBulkExec running in the Standard Job framework.

The Standard tParAccelBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

| Use an existing connection | Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. |

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional JDBC parameters for the database connection created. This property is not available when the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong> view is selected.</th>
</tr>
</thead>
</table>
| **Copy mode**                 | Select the copy mode you want to use from either:  
                                | **Basic**: Standard mode, without optimisation.  
                                | **Parallel**: Allows you to use several internal ParAccel APIs in order to optimise loading speed. |
| **Filename**                  | Name of the file to be loaded. |
| **Warning:**                  | **Warning:** This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server. |
| **File Type**                 | Select the file type from the list. |
| **Field Layout**              | Select the field layout from the list. |
| **Field separator**           | Character, string or regular expression to separate fields. |
| **Explicit IDs**              | The ID is already present in the file to be loaded or will be set by the database. |
| **Remove Quotes**             | Select this check box to remove quotation marks from the file to be loaded. |
| **Max. Errors**               | Type in the maximum number of errors before your Job stops. |
| **Date Format**               | Type in the date format to be used. |
| **Time/Timestamp Format**     | Enter the date and hour format to be used. |
| **Additional COPY Options**   | Enter the specific, customized ParAccel option that you want to use. |
| **Log file**                  | Browse to or enter the access path to the log file in your directory. |
| **Logging level**             | Select the information type you want to record in your log file. |
tParAccelBulkExec

<table>
<thead>
<tr>
<th>tStat Catcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Usage

#### Usage rule

This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a Row > Reject link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2474.

#### Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

#### Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

### Related scenarios

For related scenarios, see:

- Inserting transformed data in MySQL database on page 2482 of tMysqlOutputBulk.
- Inserting data in bulk in MySQL database on page 2489 of tMysqlOutputBulkExec.
- Truncating and inserting file data into an Oracle database on page 2681 of tOracleBulkExec.
tParAccelClose

Closes a transaction.
The tParAccelClose closes the transaction committed in the connected DB.

**tParAccelClose Standard properties**

These properties are used to configure tParAccelClose running in the Standard Job framework.
The Standard tParAccelClose component belongs to the Databases family.
The component in this framework is available in all **Talend products**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the <strong>tParAccelConnection</strong> component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is to be used along with ParAccel components, especially with **tParAccelConnection** and **tParAccelCommit**. |
| Dynamic settings | Click the [+ button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the **Basic settings** view becomes unusable. For more information on **Dynamic**... |
settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
### tParAccelCommit

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus provides gain in performance.

The tParAccelCommit validates the data processed through the job into the connected DB.

### tParAccelCommit Standard properties

These properties are used to configure tParAccelCommit running in the Standard Job framework.

The Standard tParAccelCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

#### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tParAccelConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tParAccelCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

#### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

#### Usage

**Usage rule**

This component is more commonly used with other tParAccel* components, especially with the tParAccelConnection and tParAccelRollback components.

**Dynamic settings**

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces...
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For tParAccelCommit related scenario, see Inserting data in mother/daughter tables on page 2426
tParAccelConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.
The tParAccelConnection opens a connection to the database for a current transaction.

tParAccelConnection Standard properties

These properties are used to configure tParAccelConnection running in the Standard Job framework.
The Standard tParAccelConnection component belongs to the Databases and the ELT families.
The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child. This option is incompatible with the <strong>Use dynamic job</strong> and <strong>Use an independent process to run subjob</strong> options of the</td>
</tr>
</tbody>
</table>
tParAccelConnection

| tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail. |

Advanced settings

| Auto Commit | Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |

| tStatCatcher Statistics | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

Usage

| Usage rule | This component is more commonly used with other tParAccel* components, especially with the tParAccelCommit and tParAccelRollback components. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Related scenario

For tParAccelConnection related scenario, see tMysqlConnection on page 2425
tParAccelInput

Reads a database and extracts fields based on a query.

tParAccelInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

tParAccelInput Standard properties

These properties are used to configure tParAccelInput running in the Standard Job framework.

The Standard tParAccelInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in</strong>: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository</strong>: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Database icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view.</td>

<tr>
<td></td>
<td>For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

| **Host** | Database server IP address. |
| **Port** | Listening port number of the DB server. |
| **Database** | Name of the database |
| **Schema** | Exact name of the schema |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In**: | You create and store the schema locally for this component only. |
| **Repository**: | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:** | |
| • **View schema**: choose this option to view the schema only. | |
| • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. | |
| • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. | |
| **Table name** | Name of the table to be read. |
**Query type and Query**
Enter your DB query paying particularly attention to sequence the fields properly in order to match the schema definition.

**Guess Query**
Click the **Guess Query** button to generate the query which corresponds to your table schema in the Query field.

**Guess schema**
Click the **Guess schema** button to retrieve the table schema.

**Advanced settings**

**Additional JDBC Parameters**
Specify additional JDBC parameters for the database connection created.
This property is not available when the Use an existing connection check box in the Basic settings view is selected.

**Use cursor**
When selected, helps to decide the row set to work with at a time and thus optimize performance.

**Trim all the String/Char columns**
Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**
Remove leading and trailing whitespace from defined columns.

**tStat Catcher Statistics**
Select this check box to collect log data at the component level.

**Global Variables**

**Global Variables**

**NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.
For further information about variables, see **Talend Studio User Guide**.

**Usage**

**Usage rule**
This component covers all possible SQL queries for ParAccel databases.
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the
missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For related scenarios, see:
**tParAccelOutput**

Executes the action defined on the table and/or on the data of a table, according to the input flow form the previous component.

The tParAccelOutput writes, updates, modifies or deletes the data in a database.

**tParAccelOutput Standard properties**

These properties are used to configure tParAccelOutput running in the Standard Job framework.

The Standard tParAccelOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.

2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see  Talend Studio User Guide.

<table>
<thead>
<tr>

<td>On the data of the table defined, you can perform:</td>
</tr>
<tr>
<td></td>
<td>Insert: Add new entries to the table. If duplicates are found, job stops.</td>
</tr>
<tr>
<td></td>
<td>Update: Make changes to existing entries</td>
</tr>
<tr>
<td></td>
<td>Insert or update: Insert a new record. If the record with the given</td>
</tr>
<tr>
<td></td>
<td>reference already exists, an update would be made.</td>
</tr>
<tr>
<td></td>
<td>Update or insert: Update the record with the given reference. If the record</td>
</tr>
<tr>
<td></td>
<td>does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td></td>
<td>Delete: Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
Warning:
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Built-In: You create and store the schema locally for this component only.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Die on error

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

Advanced settings

Use alternate schema
Select this option to use a schema other than the one specified by the component that establishes the database.
connection (that is, the component selected from the Component list drop-down list in Basic settings view). After selecting this option, provide the name of the desired schema in the Schema field. This option is available when Use an existing connection is selected in Basic settings view.

### Additional JDBC Parameters
Specify additional JDBC parameters for the database connection created. This property is not available when the Use an existing connection check box in the Basic settings view is selected.

### Commit every
Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

### Additional Columns
This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

**Name:** Type in the name of the schema column to be altered or inserted as new column

**SQL expression:** Type in the SQL statement to be executed in order to alter or insert the relevant column data.

**Position:** Select Before, Replace or After following the action to be performed on the reference column.

**Reference column:** Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.

### Use field options
Select this check box to customize a request, especially when there is double action on data.

### Use Batch
Select this check box to activate the batch mode for data processing.

**Note:**
This check box is available only when you have selected the Insert, Update, or Delete option in the Action on data option.

### Batch Size
Specify the number of records to be processed in each batch. This field appears only when the Use batch mode check box is selected.

### tStat Catcher Statistics
Select this check box to collect log data at the component level.
## Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td><strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_INSERTED</strong>: the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_DELETED</strong>: the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>NB_LINE_REJECTED</strong>: the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td><strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>

</tr>
</tbody>
</table>

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in a ParAccel database. It enables you to create a reject flow, with a <strong>Row &gt; Rejects</strong> link filtering the data in error. For a usage example, see <strong>Retrieving data in error with a Reject link</strong> on page 2474.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the <strong>[+]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
<tr>
<td></td>
<td>The <strong>Dynamic settings</strong> table is available only when the <strong>Use an existing connection</strong> check box is selected in the <strong>Basic settings</strong> view. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable.</td>
</tr>
<tr>
<td></td>
<td>For examples on using dynamic parameters, see <strong>Reading data from databases through context-based dynamic connections</strong> on page 2446 and <strong>Reading data from different MySQL databases using dynamically loaded connection parameters</strong> on page 497. For more information on <strong>Dynamic settings</strong> and context variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>
Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

**Related scenarios**

For a related scenario, see:

- Inserting a column and altering data using `tMysqlOutput` on page 2466.
tParAccelOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tParAccelOutputBulkExec component, detailed in a different section. The advantage of using two separate steps is that the data can be transformed before it is loaded in the database.

The tParAccelOutputBulk writes a file with columns based on the defined delimiter and the ParAccel standards.

**tParAccelOutputBulk Standard properties**

These properties are used to configure tParAccelOutputBulk running in the Standard Job framework.

The Standard tParAccelOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>File Name</td>
<td>Name of the file to be generated.</td>
</tr>
<tr>
<td><strong>Warning:</strong></td>
<td>This file is generated on the local machine or a shared folder on the LAN.</td>
</tr>
<tr>
<td>Append</td>
<td>Select this check box to add the new rows at the end of the file</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong></td>
<td>You create and store the schema locally for this component only.</td>
</tr>
</tbody>
</table>
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Include header</strong></td>
<td>Select this check box to include the column header.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding type from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
Usage

**Usage rule**
This component is to be used along with **tParAccelBulkExec** component. Used together they offer gains in performance while feeding a ParAccel database.

**Component family**
Databases/ParAccel

Related scenarios

For use cases in relation with **tParAccelOutputBulk**, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tParAccelOutputBulkExec

Improves performance when loading data in ParAccel database.

The tParAccelOutputBulk and tParAccelBulkExec are generally used together in a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in tParAccelOutputBulkExec.

The tParAccelOutputBulkExec performs an Insert action on the data.

tParAccelOutputBulkExec Standard properties

These properties are used to configure tParAccelOutputBulkExec running in the Standard Job framework.

The Standard tParAccelOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

For related scenarios, see:

- Inserting transformed data in MySQL database on page 2482 of tMysqlOutputBulk.
- Inserting data in bulk in MySQL database on page 2489 of tMysqlOutputBulkExec.
- Truncating and inserting file data into an Oracle database on page 2681 of tOracleBulkExec.
**tParAccelRollback**

Avoids to commit part of a transaction involuntarily.

The tParAccelRollback cancels the transaction commit in the connected DB.

**tParAccelRollback Standard properties**

These properties are used to configure tParAccelRollback running in the Standard Job framework.

The Standard tParAccelRollback component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tParAccelConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

### Usage

| Usage rule | This component is more commonly used with other tParAccel* components, especially with the tParAccelConnection and tParAccelCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the **Component List** box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection. |
Related scenario

For tParAccelRollback related scenario, see tMysqlRollback on page 2491.
tParAccelRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tParAccelRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn’t provide output.

**tParAccelRow Standard properties**

These properties are used to configure tParAccelRow running in the Standard Job framework.

The Standard tParAccelRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*. 2832
| **Host** | Database server IP address |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database |
| **Schema** | Exact name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| **Built-In**: You create and store the schema locally for this component only. **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| **Table Name** | Name of the table to be read. |
| **Query type** | Either Built-in or Repository. |
| **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder. **Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in. |
| **Guess Query** | Click the Guess Query button to generate the query which corresponds to your table schema in the Query field. |
| **Query** | Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition. |
**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional JDBC parameters for the database connection created. This property is not available when the Use an existing connection check box in the Basic settings view is selected.</th>
</tr>
</thead>
</table>
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.  

**Note:**  
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of Object and this component is usually followed by tParseRecordSet. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by '?' in the SQL instruction of the Query field in the Basic Settings tab.  

- **Parameter Index**: Enter the parameter position in the SQL instruction.  
- **Parameter Type**: Enter the parameter type.  
- **Parameter Value**: Enter the parameter value.  

**Note:**  
This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

| **Global Variables** | **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.  

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the |
|---------------------|---------------------------------------------------------------------------------------------------------------|
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component offers the flexibility benefit of the DB query and covers all possible SQL queries. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Limitation

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

Related scenarios

For a related scenario, see:

- Combining two flows for selective output on page 2503
- Procedure on page 622.
- Removing and regenerating a MySQL table index on page 2497.
tParAccelSCD

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

The tParAccelSCD reflects and tracks changes in a dedicated ParAccel SCD table.

**tParAccelSCD Standard properties**

These properties are used to configure tParAccelSCD running in the Standard Job framework.

The Standard tParAccelSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the Repository file where properties are stored. The following fields are pre-filled in using fetched data.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<p>| Connection type | Select the relevant driver on the list. |
| Host | Database server IP address. |</p>
<table>
<thead>
<tr>
<th><strong>Port</strong></th>
<th>Listening port number of DB server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the DB schema.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. 
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window. |
| **Built-in** | The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*. |
| **Repository** | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs. 
For more information, see *SCD management methodology* on page 2511. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values.  
**Warning:**  
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

Advanced settings

Additional JDBC Parameters

Specify additional JDBC parameters for the database connection created.

This property is not available when the Use an existing connection check box in the Basic settings view is selected.

End date time details

Specify the time value of the SCD end date time setting in the format of HH:mm:ss. The default value for this field is 12:00:00.

This field appears only when SCD Type 2 is used and Fixed year value is selected for creating the SCD end date.

Debug mode

Select this check box to display each step during processing entries in a database.

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

Global Variables

NB_LINE_UPDATED: the number of rows updated. This is an After variable and it returns an integer.

NB_LINE_INSERTED: the number of rows inserted. This is an After variable and it returns an integer.

NB_LINE_REJECTED: the number of rows rejected. This is an After variable and it returns an integer.

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component is used as Output component. It requires an Input component and Row main link as input.

Dynamic settings

Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to acces
s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation        | This component does not support using SCD type 0 together with other SCD types. |

### Related scenario

For related scenarios, see tMysqlSCD on page 2508.
tParseRecordSet

Parses a recordset rather than individual records from a table.

The tParseRecordSet parses a set of records from a database table or DB query and possibly returns single records.

**tParseRecordSet Standard properties**

These properties are used to configure tParseRecordSet running in the Standard Job framework.

The Standard tParseRecordSet component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Prev. Comp. Column list</th>
<th>Set the column from the database that holds the recordset.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>

Related Scenario

For an example of **tParseRecordSet** in use, see [Using PreparedStatement objects to query data](#) on page 2498.
tPatternUnmasking

Unmasks data masked with the tPatternMasking component to retrieve the original data.

The tPatternUnmasking component can only unmask data masked with the tPatternMasking component, using the FF1 with AES or FF1 with SHA-2 method combined with a user-defined password.

For each column to unmask from the input data, select the value from the Field type list, and enter the Values, Path, Range and Date Range values set when the input data was masked using tPatternMasking.

tPatternUnmasking Standard properties

These properties are used to configure tPatternUnmasking running in the Standard Job framework.

The Standard tPatternUnmasking component belongs to the Data Quality family.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Sync columns to retrieve the schema from the previous component connected in the Job. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td>• View schema: choose this option to view the schema only. • Change to built-in property: choose this option to change the schema to Built-in for local changes. • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
<td></td>
</tr>
<tr>
<td>The output schema of this component contains one read-only column, ORIGINAL_MARK. This column identifies by true or false if the record is an masked or original respectively.</td>
<td></td>
</tr>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
<tr>
<td>Modifications</td>
<td>Define in the table what fields to unmask and how to unmask them:</td>
</tr>
</tbody>
</table>
Use the same settings for the **Field type**, **Values**, **Path**, **Range** and **Date Range** columns as the ones used for masking the input data with the tPatternMasking component.

**Column to unmask**: Select the column from the input flow that contains the data to be unmasked.

Each column is processed sequentially, meaning that data unmasking operations will be performed on the data from the first column, the second column, and so on.

In a column, each data field is a fixed length field, except the last data field.

For fixed length fields, each value must contain the same number of characters, for example: "30001,30002,30003" or "FR,EN".

In a column, the last Enumeration or Enumeration from file data field is a variable length field.

For variable length fields, each value might not always contain the same number of characters, for example: "30001,300023,30003" or "FR,ENG".

**Field type**: Select the field type the data belongs to.

- **Interval**: When selected, set a range of numeric values used for masking purposes in the **Range** field, using the following syntax: "<min>,<max>".

  The number of unmasked characters from the input data corresponds to the number of characters of the maximum value.

  For example, "1,999" will be interpreted as "001,999", which means that three characters from the input data will be masked by a value randomly selected from the defined range of values.

- **Enumeration**: When selected, enter a comma-separated list of values to be used for masking data in the **Values** field, using the following syntax: "value1,value2,value3".

- **Enumeration from file**: When selected, set the path to the CSV file containing a list of values used for masking data in the **Path** field. The file must contain one value per row and each value must be unique.

- **Date pattern (YYYYMMDD)**: When selected, set a range of years in the **Date Range** field, using the following syntax: "<min_year>,<max_year>".

  Years can only have four digits, for example: "1900,2100".

  The input dates to be masked must follow the YYYYMMDD pattern, for example: 20180101.

  For example, if the input date is 20180101 and the value in the **Date Range** is "1900,2100", 19221221 could be the output date.

In the **Values**, **Path**, **Range** and **Date Range**, values must be enclosed in double quotes.

When the input data is invalid, meaning that a value does not match the pattern defined in the component, the generated value is **null**.
## Advanced settings

| **Method** | From this list, select the Format-Preserving Encryption (FPE) algorithm that was used to mask data, **FF1 with AES** or **FF1 with SHA-2**:

The **FF1 with AES** method is based on the Advanced Encryption Standard in CBC mode. The **FF1 with SHA-2** method depends on the secure hash function HMAC-256.

Java 8u161 is the minimum required version to use the **FF1 with AES** method. To be able to use this FPE method with Java versions earlier than 8u161, download the Java Cryptography Extension (JCE) unlimited strength jurisdiction policy files from Oracle website. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Password for FF1 methods</strong></td>
<td>To unmask data, the <strong>FF1 with AES</strong> and <strong>FF1 with SHA-2</strong> methods require the password specified in the <strong>Password for FF1 methods</strong> field when the data was masked with the tPatternMasking component.</td>
</tr>
<tr>
<td><strong>Use tweaks</strong></td>
<td>If tweaks have been generated while encrypting the data, select this check box. When selected, the <strong>Column containing tweaks</strong> list is displayed. A tweak allows to decrypt all data of a record.</td>
</tr>
<tr>
<td><strong>Column containing tweaks</strong></td>
<td>Available when the <strong>Use tweaks</strong> check box is selected. Select the column that contains the tweaks. If you do not see it, make sure you have declared in the input component the tweaks generated by the masking component.</td>
</tr>
</tbody>
</table>
| **Seed for random generator** | Set a random number if you want to generate the same sample of substitute data in each execution of the Job. The seed is not set by default.

If you do not set the seed, the component creates a new random seed for each Job execution. Repeating the execution with a different seed will result in a different sample being generated. |
| **Encoding** | Select the encoding from the list or select **Custom** and define it manually. If you select Custom and leave the field empty, the supported encodings depend on the JVM that you are using. This field is compulsory for the file encoding.

When you set **Field type** to **Enumeration from file**, define the file path in **Path (CSV File)**. |
| **Output the original row?** | Select this check box to output original data rows in addition to the substitute data. Outputting both the original and substitute data can be useful in debug or test processes. |
| **Should Null input return NULL?** | This check box is selected by default. When selected, the component outputs null when input values are null. Otherwise, the component returns the default value when the input is null, that is an empty string for string values, 0 for numeric values and the current date for date values.

If the input is null, the **Generate Sequence** function will not return null, even if the check box is selected. |
| **Should EMPTY input return EMPTY?** | When this check box is selected, empty values are left unchanged in the output data. Otherwise, the selected functions are applied to the input data. |
Send invalid data to "Invalid" output flow

This check box is selected by default.
- Selected: When the data can be unmasked, they are sent to the main flow. Otherwise, the data are sent to the "Invalid" output flow.
- Cleared: The data are sent to the main flow.

Invalid data are any values that do not match the pattern.

---

tStat Catcher  Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

---

Usage

Usage rule

This component is an intermediary step. It requires an input and output flows.

---

Unmasking Australian phone numbers

The Job in this scenario uses the tPatternUnmasking component to retrieve the original Australian phone numbers masked with the tPatternMasking component.

The original Australian phone numbers are 02 7010 8328, 08 5550 3018 and 07 5550 5556.

This scenario describes a Job which uses:
- the tFileInputDelimited component to read a CSV file that contains Australian phone numbers masked with the tPatternMasking component;
- the tPatternUnmasking component to unmask the input Australian phone numbers;
- the tFileOutputDelimited component to output masked and original phone numbers values.

To replicate this scenario, retrieve the masked_phonenumbers.csv file from the Downloads tab of the online version of this page at https://help.talend.com.

This file contains Australian phone numbers masked with the tPatternMasking component, using the FF1 with AES method combined with a user-defined password.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput, tPatternUnmasking and tFileOutputDelimited.
2. Connect the three components together using Row > Main links.

Results

---

2845
Configuring the input component

Procedure

1. Double-click tFileInputDelimited to open its Basic settings view in the Component tab.

   ![Basic settings view](image)

   - File name/Stream: Set the path to the file that contains the encrypted masked phone numbers.
     - Example: In this example, set the path to the masked_phonenumbers.csv file.
   - CSV options: Select this check box.
   - Edit schema: Click the [...] button to add a column of String type.
   - OK: Click OK and accept to propagate the changes when prompted.

2. In the File name/Stream field, set the path to the file that contains the encrypted masked phone numbers.

   Example
   - In this example, set the path to the masked_phonenumbers.csv file.

3. Select the CSV options check box.

4. Click the [...] button next to Edit schema and use the [+ button in the dialog box to add a column of String type.

   ![Edit schema dialog box](image)

5. Click OK in the dialog box and accept to propagate the changes when prompted.

6. In the Header field, enter 1.
Configuring the unmasking operations

Configure one unmasking operation for each part of the input phone numbers. Separators will be left unchanged in the unmasked values.

In the Modifications table, the settings must be the same as the ones used for the masking operations performed by the tPatternMasking component.

About this task

The masked Australian phone numbers use the XX XXXX XXXX format:

- A two-digit prefix
- A space used as a separator
- A four-digit code region
- A space used as a separator
- A four-digit line number

Procedure

1. Double-click tPatternUnmasking to display its Basic settings view in the Component tab.

2. If required, click Sync columns to retrieve the schema defined in the input component.

3. Click the Edit schema button to open the schema dialog box.

   tPatternUnmasking adds a read-only column to the output schema.
The ORIGINAL_MARK column labels output records:

- Original records are labeled with the true label.
- Substitute records are labeled with the false label.

4. In the Modifications table, click the [+ ] button to add three rows.
   Each row corresponds to an unmasking operation for a part of the input phone numbers.

5. In the Modifications table, edit the first row to configure the unmasking operation for prefixes:
   a) From the Column to unmask field, select the column which holds the data to be unmasked.
      In this example, select PhoneNumber.
   b) From the Field type field, select Enumeration as the field type the data belongs to and enter "02, 03, 07, 08" in the Values field.

6. In the Modifications table, edit the second row to configure the unmasking operation for code regions:
   a) From the Column to unmask field, select the column which holds the data to be unmasked.
      In this example, select PhoneNumber.
   b) From the Field type field, select Enumeration as the field type the data belongs to and enter "5550, 7010" in the Values field.

7. In the Modifications table, configure the third row to unmask the four-digit line numbers:
   a) From the Column to unmask field, select the column which holds the data to be unmasked.
      In this example, select PhoneNumber.
   b) From the Field type field, select Interval as the field type the data belongs to and enter "0000, 99999" in the Range field.

8. Click the Advanced settings tab and select the Output the original row? check box.
   The Job will output original and substitute records.

9. From the Method list, select the method used when the data was masked using the tPatternMasking component.

   Example
   In this example, select FF1 with AES.

10. In the Password for FF1 methods, enter the user-defined password used when the data was masked using the tPatternMasking component.
Example
In this example, enter "talend".

Configuring the output component and executing the Job

Procedure
1. Double-click the tFileOutputDelimited component to display the Basic settings view and define the component properties.
2. In the File Name field, set the path to the file that will contain the unmasked values.
3. Press F6 to save and execute the Job.

Results

ORIGINAL_MARK;PhoneNumber
false;02 7010 8328
false;08 5550 3018
false;07 5550 5556

The unmasked records are labeled as true.

Given that a format-encryption method and a password were used to bijectively mask phone numbers, the component retrieved back the original phone numbers.

tPatternUnmasking properties for Apache Spark Batch

These properties are used to configure tPatternUnmasking running in the Spark Batch Job framework. The Spark Batch tPatternUnmasking component belongs to the Data Quality family.

Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</th>

</tr>
</tbody>
</table>
true or false if the record is an masked or original respectively.

Built-In: You create and store the schema locally for this component only.

Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Modifications

Define in the table what fields to unmask and how to unmask them:

Use the same settings for the Field type, Values, Path, Range and Date Range columns as the ones used for masking the input data with the tPatternMasking component.

Column to unmask: Select the column from the input flow that contains the data to be unmasked.

Each column is processed sequentially, meaning that data unmasking operations will be performed on the data from the first column, the second column, and so on.

In a column, each data field is a fixed length field, except the last data field.

For fixed length fields, each value must contain the same number of characters, for example: "30001,30002,30003" or "FR,EN".

In a column, the last Enumeration or Enumeration from file data field is a variable length field.

For variable length fields, each value might not always contain the same number of characters, for example: "30001,300023,30003" or "FR,ENG".

Field type: Select the field type the data belongs to.

- Interval: When selected, set a range of numeric values used for masking purposes in the Range field, using the following syntax: ":<min>,<max>". The number of unmasked characters from the input data corresponds to the number of characters of the maximum value.

  For example, "1,999" will be interpreted as "001,999", which means that three characters from the input data will be masked by a value randomly selected from the defined range of values.

- Enumeration: When selected, enter a comma-separated list of values to be used for masking data in the Values field, using the following syntax: "value1,value2,value3".

- Enumeration from file: When selected, set the path to the CSV file containing a list of values used for masking data in the Path field. The file must contain one value per row and each value must be unique.

- Date pattern (YYYYMMDD): When selected, set a range of years in the Date Range field, using the following syntax: "<min_year>,<max_year>". Years can only have four digits, for example: "1900,2100". The input dates to be masked must follow the YYYYMMDD pattern, for example: 20180101.
For example, if the input date is 20180101 and the value in the Date Range is "1900,2100", 19221221 could be the output date.

In the Values, Path, Range and Date Range, values must be enclosed in double quotes.

When the input data is invalid, meaning that a value does not match the pattern defined in the component, the generated value is null.

### Advanced settings

| Method          | From this list, select the Format-Preserving Encryption (FPE) algorithm that was used to mask data, FF1 with AES or FF1 with SHA-2:  
|                | The FF1 with AES method is based on the Advanced Encryption Standard in CBC mode. The FF1 with SHA-2 method depends on the secure hash function HMAC-256.  
|                | Java 8u161 is the minimum required version to use the FF1 with AES method. To be able to use this FPE method with Java versions earlier than 8u161, download the Java Cryptography Extension (JCE) unlimited strength jurisdiction policy files from Oracle website. |
| Password for FF1 methods | To unmask data, the FF1 with AES and FF1 with SHA-2 methods require the password specified in the Password for FF1 methods field when the data was masked with the tPatternMasking component. |
| Use tweaks     | If tweaks have been generated while encrypting the data, select this check box. When selected, the Column containing tweaks list is displayed. A tweak allows to decrypt all data of a record. |
| Column containing tweaks | Available when the Use tweaks check box is selected. Select the column that contains the tweaks. If you do not see it, make sure you have declared in the input component the tweaks generated by the masking component. |
| Seed for random generator | Set a random number if you want to generate the same sample of substitute data in each execution of the Job. The seed is not set by default.  
|                | If you do not set the seed, the component creates a new random seed for each Job execution. Repeating the execution with a different seed will result in a different sample being generated. |
| Encoding       | Select the encoding from the list or select Custom and define it manually. If you select Custom and leave the field empty, the supported encodings depend on the JVM that you are using. This field is compulsory for the file encoding.  
|                | When you set Field type to Enumeration from file, define the file path in Path (CSV File). |
| Output the original row? | Select this check box to output original data rows in addition to the substitute data. Outputting both the original and substitute data can be useful in debug or test processes. |
### Should Null input return NULL?

This check box is selected by default. When selected, the component outputs `null` when input values are `null`. Otherwise, the component returns the default value when the input is `null`, that is an empty string for string values, 0 for numeric values and the current date for date values.

If the input is `null`, the Generate Sequence function will not return `null`, even if the check box is selected.

### Should EMPTY input return EMPTY?

When this check box is selected, empty values are left unchanged in the output data. Otherwise, the selected functions are applied to the input data.

### Send invalid data to "Invalid" output flow

This check box is selected by default.

- **Selected**: When the data can be unmasked, they are sent to the main flow. Otherwise, the data are sent to the "Invalid" output flow.
- **Cleared**: The data are sent to the main flow.

Invalid data are any values that do not match the pattern.

### tStat Catcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Usage

#### Usage rule

This component is used as an intermediate step.

This component, along with the Spark Batch component Palette it belongs to, appears only when you are creating a Spark Batch Job.

Note that in this documentation, unless otherwise explicitly stated, a scenario presents only Standard Jobs, that is to say traditional Talend data integration Jobs.

#### Spark Connection

In the Spark Configuration tab in the Run view, define the connection to a given Spark cluster for the whole Job. In addition, since the Job expects its dependent jar files for execution, you must specify the directory in the file system to which these jar files are transferred so that Spark can access these files:

- **Yarn mode** (Yarn client or Yarn cluster):
  - When using Google Dataproc, specify a bucket in the Google Storage staging bucket field in the Spark configuration tab.
  - When using HDInsight, specify the blob to be used for Job deployment in the Windows Azure Storage configuration area in the Spark configuration tab.
  - When using Altus, specify the S3 bucket or the Azure Data Lake Storage for Job deployment in the Spark configuration tab.
  - When using Qubole, add a tS3Configuration to your Job to write your actual business data in the S3 system with Qubole. Without tS3Configuration, this business data is written in the Qubole HDFS system and destroyed once you shut down your cluster.
  - When using on-premise distributions, use the configuration component corresponding to the file
system your cluster is using. Typically, this system is HDFS and so use tHDFSConfiguration.

- **Standalone mode**: use the configuration component corresponding to the file system your cluster is using, such as tHDFSConfiguration or tS3Configuration.

If you are using Databricks without any configuration component present in your Job, your business data is written directly in DBFS (Databricks Filesystem).

This connection is effective on a per-Job basis.

---

### tPatternUnmasking properties for Apache Spark Streaming

These properties are used to configure tPatternUnmasking running in the Spark Streaming Job framework.

The Spark Streaming tPatternUnmasking component belongs to the Data Quality family.

#### Basic settings

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
</tr>
</thead>
</table>
| A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Sync columns** to retrieve the schema from the previous component connected in the Job. Click **Edit schema** to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  

The output schema of this component contains one read-only column, ORIGINAL_MARK. This column identifies by true or false if the record is an masked or original respectively. |

| Built-In | You create and store the schema locally for this component only. |
|----------|

| Repository | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

<table>
<thead>
<tr>
<th>Modifications</th>
</tr>
</thead>
<tbody>
<tr>
<td>Define in the table what fields to unmask and how to unmask them: Use the same settings for the Field type, Values, Path, Range and Date Range columns as the ones used for masking the input data with the tPatternMasking component.</td>
</tr>
</tbody>
</table>
**Column to unmask:** Select the column from the input flow that contains the data to be unmasked.

Each column is processed sequentially, meaning that data unmasking operations will be performed on the data from the first column, the second column, and so on.

In a column, each data field is a fixed length field, except the last data field.

For fixed length fields, each value must contain the same number of characters, for example: "30001, 30002, 30003" or "FR, EN".

In a column, the last **Enumeration** or **Enumeration from file** data field is a variable length field.

For variable length fields, each value might not always contain the same number of characters, for example: "30001, 300023, 30003" or "FR, ENG".

**Field type:** Select the field type the data belongs to.

- **Interval:** When selected, set a range of numeric values used for masking purposes in the **Range** field, using the following syntax: "<min>,<max>".

  The number of unmasked characters from the input data corresponds to the number of characters of the maximum value.

  For example, "1,999" will be interpreted as "001,999", which means that three characters from the input data will be masked by a value randomly selected from the defined range of values.

- **Enumeration:** When selected, enter a comma-separated list of values to be used for masking data in the **Values** field, using the following syntax: "value1,value2,value3".

- **Enumeration from file:** When selected, set the path to the CSV file containing a list of values used for masking data in the **Path** field. The file must contain one value per row and each value must be unique.

- **Date pattern (YYYYMMDD):** When selected, set a range of years in the **Date Range** field, using the following syntax: "<min_year>,<max_year>".

  Years can only have four digits, for example: "1900,2100".

  The input dates to be masked must follow the YYYYMMDD pattern, for example: 20180101.

  For example, if the input date is 20180101 and the value in the **Date Range** is "1900,2100", 19221221 could be the output date.

In the **Values**, **Path**, **Range** and **Date Range**, values must be enclosed in double quotes.

When the input data is invalid, meaning that a value does not match the pattern defined in the component, the generated value is **null**.

### Advanced settings

<table>
<thead>
<tr>
<th>Method</th>
<th>From this list, select the Format-Preserving Encryption (FPE) algorithm that was used to mask data, <strong>FF1 with AES</strong> or <strong>FF1 with SHA-2</strong>.</th>
</tr>
</thead>
</table>
The **FF1 with AES** method is based on the Advanced Encryption Standard in CBC mode. The **FF1 with SHA-2** method depends on the secure hash function HMAC-256. Java 8u161 is the minimum required version to use the **FF1 with AES** method. To be able to use this FPE method with Java versions earlier than 8u161, download the Java Cryptography Extension (JCE) unlimited strength jurisdiction policy files from Oracle website.

### Password for FF1 methods

To unmask data, the **FF1 with AES** and **FF1 with SHA-2** methods require the password specified in the **Password for FF1 methods** field when the data was masked with the tPatternMasking component.

### Use tweaks

If tweaks have been generated while encrypting the data, select this check box. When selected, the **Column containing tweaks** list is displayed. A tweak allows to decrypt all data of a record.

### Column containing tweaks

Available when the **Use tweaks** check box is selected. Select the column that contains the tweaks. If you do not see it, make sure you have declared in the input component the tweaks generated by the masking component.

### Seed for random generator

Set a random number if you want to generate the same sample of substitute data in each execution of the Job. The seed is not set by default.

If you do not set the seed, the component creates a new random seed for each Job execution. Repeating the execution with a different seed will result in a different sample being generated.

### Encoding

Select the encoding from the list or select **Custom** and define it manually. If you select **Custom** and leave the field empty, the supported encodings depend on the JVM that you are using. This field is compulsory for the file encoding.

When you set **Field type** to **Enumeration from file**, define the file path in **Path (CSV File)**.

### Output the original row?

Select this check box to output original data rows in addition to the substitute data. Outputting both the original and substitute data can be useful in debug or test processes.

### Should Null input return NULL?

This check box is selected by default. When selected, the component outputs null when input values are null. Otherwise, the component returns the default value when the input is null, that is an empty string for string values, 0 for numeric values and the current date for date values.

If the input is null, the **Generate Sequence** function will not return null, even if the check box is selected.

### Should EMPTY input return EMPTY?

When this check box is selected, empty values are left unchanged in the output data. Otherwise, the selected functions are applied to the input data.

### Send invalid data to "Invalid" output flow

This check box is selected by default.

- Selected: When the data can be unmasked, they are sent to the main flow. Otherwise, the data are sent to the "Invalid" output flow.
- Cleared: The data are sent to the main flow. Invalid data are any values that do not match the pattern.

**tStat Catcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Usage

**Usage rule**

This component is used as an intermediate step. This component, along with the Spark Batch component Palette it belongs to, appears only when you are creating a Spark Batch Job.

Note that in this documentation, unless otherwise explicitly stated, a scenario presents only **Standard** Jobs, that is to say traditional **Talend** data integration Jobs.

**Spark Connection**

In the Spark Configuration tab in the Run view, define the connection to a given Spark cluster for the whole Job. In addition, since the Job expects its dependent jar files for execution, you must specify the directory in the file system to which these jar files are transferred so that Spark can access these files:

- **Yarn mode** (Yarn client or Yarn cluster):
  - When using Google Dataproc, specify a bucket in the [Google Storage staging bucket](#) field in the Spark configuration tab.
  - When using HDInsight, specify the blob to be used for Job deployment in the [Windows Azure Storage configuration](#) area in the Spark configuration tab.
  - When using Altus, specify the S3 bucket or the Azure Data Lake Storage for Job deployment in the Spark configuration tab.
  - When using Qubole, add a tS3Configuration to your Job to write your actual business data in the S3 system with Qubole. Without tS3Configuration, this business data is written in the Qubole HDFS system and destroyed once you shut down your cluster.
  - When using on-premise distributions, use the configuration component corresponding to the file system your cluster is using. Typically, this system is HDFS and so use tHDFSConfiguration.

- **Standalone mode**: use the configuration component corresponding to the file system your cluster is using, such as tHDFSConfiguration or tS3Configuration.

If you are using Databricks without any configuration component present in your Job, your business data is written directly in DBFS (Databricks Filesystem).

This connection is effective on a per-Job basis.
tPivotToColumnsDelimited

Fine-tunes the selection of data to output.

The tPivotToColumnsDelimited outputs data based on an aggregation operation carried out on a pivot column.

**tPivotToColumnsDelimited Standard properties**

These properties are used to configure tPivotToColumnsDelimited running in the Standard Job framework.

The Standard tPivotToColumnsDelimited component belongs to the File family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Pivot column</strong></td>
<td>Select the column from the incoming flow that will be used as pivot for the aggregation operation.</td>
</tr>
<tr>
<td><strong>Aggregation column</strong></td>
<td>Select the column from the incoming flow that contains the data to be aggregated.</td>
</tr>
<tr>
<td><strong>Aggregation function</strong></td>
<td>Select the function to be used in case several values are available for the pivot column.</td>
</tr>
<tr>
<td><strong>Group by</strong></td>
<td>Define the aggregation sets, the values of which will be used for calculations.</td>
</tr>
<tr>
<td><strong>Input Column</strong></td>
<td><strong>Input Column</strong>: Match the input column label with your output columns, in case the output label of the aggregation set needs to be different.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name or path to the file to be processed and/or the variable to be used. For further information about how to define and use a variable in a Job, see <em>Talend Studio User Guide</em>.</td>
</tr>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields of the output file.</td>
</tr>
<tr>
<td><strong>Row separator</strong></td>
<td>String (ex: <code>\n</code> on Unix) to distinguish rows in the output file.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_OUT</strong></td>
<td>the number of rows written to the file by the component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable</td>
</tr>
</tbody>
</table>
and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component requires an input flow.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Using a pivot column to aggregate data

The following scenario describes a Job that aggregates data from a delimited input file, using a defined pivot column.

### Dropping and linking components

**Procedure**

1. Drop the following component from the Palette to the design workspace: **tFileInputDelimited**, **tPivotToColumnsDelimited**.
2. Link the two components using a Row > Main connection.

### Configuring the components

**Set the input component**

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its Basic settings view.
2. Browse to the input file to fill out the **File Name** field.

The file to use as input file is made of 3 columns, including: ID, Question and the corresponding Answer

<table>
<thead>
<tr>
<th>Id</th>
<th>Question</th>
<th>Answer</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Name</td>
<td>Juan</td>
</tr>
<tr>
<td>2</td>
<td>Name</td>
<td>Jean</td>
</tr>
<tr>
<td>3</td>
<td>Name</td>
<td>John</td>
</tr>
<tr>
<td>1</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>2</td>
<td>Gender</td>
<td>F</td>
</tr>
<tr>
<td>3</td>
<td>Gender</td>
<td>M</td>
</tr>
<tr>
<td>1</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>2</td>
<td>Surgery</td>
<td>No</td>
</tr>
<tr>
<td>3</td>
<td>Surgery</td>
<td>Yes</td>
</tr>
<tr>
<td>1</td>
<td>Age</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Age</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>Age</td>
<td>42</td>
</tr>
<tr>
<td>1</td>
<td>Name</td>
<td>Mary</td>
</tr>
</tbody>
</table>

3. Define the **Row** and **Field** separators, in this example, respectively: carriage return and semi-colon

4. As the file contains a header line, define it also.

5. Set the schema describing the three columns: ID, Questions, Answers.

**Set the output component**

**Procedure**

1. Double-click the **tPivotToColumnsDelimited** component to open its **Basic settings** view.
2. In the **Pivot column** field, select the pivot column from the input schema. This is often the column presenting most duplicates (pivot aggregation values).

3. In the **Aggregation column** field, select the column from the input schema that should get aggregated.

4. In the **Aggregation function** field, select the function to be used in case duplicates are found out.

5. In the **Group by** table, add an input column that will be used to group by the aggregation column.

6. In the **File Name** field, browse to the output file path. And on the **Row** and **Field separator** fields, set the separators for the aggregated output rows and data.

## Saving and executing the Job

### Procedure

1. Press **Ctrl+S** to save your Job.

2. Press **F6** or click **Run** on the **Run** tab to execute the Job.

<table>
<thead>
<tr>
<th>id</th>
<th>Name</th>
<th>Gender</th>
<th>Surgery</th>
<th>Age</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Mary</td>
<td>M</td>
<td>Yes</td>
<td>45</td>
</tr>
<tr>
<td>2</td>
<td>Jean</td>
<td>M</td>
<td>No</td>
<td>23</td>
</tr>
<tr>
<td>3</td>
<td>John</td>
<td>F</td>
<td>Yes</td>
<td>42</td>
</tr>
</tbody>
</table>

The output file shows the newly aggregated data.
tPOP

Fetches one or more email messages from a server using the POP3 or IMAP protocol. tPOP uses the POP or IMAP protocol to connect to a specific email server. Then it fetches one or more email messages and writes the recovered information in specified files. Parameters in the Advanced settings view allows you to use filters on your selection.

**tPOP Standard properties**

These properties are used to configure tPOP running in the Standard Job framework.

The Standard tPOP component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Host</th>
<th>IP address of the email server you want to connect to.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Port number of the email server.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>User authentication data for the email server.</td>
</tr>
<tr>
<td></td>
<td>Username: enter the username you use to access your email box.</td>
</tr>
<tr>
<td></td>
<td>Password: enter the password you use to access your email box.</td>
</tr>
<tr>
<td>Output directory</td>
<td>Enter the path to the file in which you want to store the email messages you retrieve from the email server, or click the three-dot button next to the field to browse to the file.</td>
</tr>
<tr>
<td>Filename pattern</td>
<td>Define the syntax of the names of the files that will hold each of the email messages retrieved from the email server, or press Ctrl+Space to display the list of predefined patterns.</td>
</tr>
<tr>
<td>Retrieve all emails?</td>
<td>Select this check box to retrieve all email messages present on the specified server.</td>
</tr>
<tr>
<td>Number of emails to retrieve</td>
<td>Enter the number of email messages you want to retrieve. This field is available only when the Retrieve all emails? check box is cleared.</td>
</tr>
<tr>
<td>Newer email first</td>
<td>Select this check box to retrieve the most recent email messages according to the number specified in the Number of emails to retrieve field, and the email messages will be returned in chronological order. This check box is available only when the Retrieve all emails? check box, which is selected by default, is cleared.</td>
</tr>
<tr>
<td>Delete emails from server</td>
<td>Select this check box if you do not want to keep the retrieved email messages on the server.</td>
</tr>
</tbody>
</table>
**Choose the protocol**

From the list, select the protocol to be used to retrieve the email messages from the server. This protocol is the one used by the email server. If you choose the imap protocol, you will be able to select the folder from which you want to retrieve your emails.

**Use SSL**

Select this check box if your email server uses this protocol for authentication and communication confidentiality.

**Note:**

For Gmail servers, this option does not work for the pop3 protocol. Select the imap protocol and ensure that the Gmail account is configured to use imap.

**Advanced settings**

**tStatCatcher Statistics**

Select this check box to gather the job processing metadata at a job level as well as at each component level.

**Filter**

Click the plus button to add as many lines as needed to filter email messages and retrieve only a specific selection:

**Filter item:** select one of the following filter types from the list:

- **From:** email messages are filtered according to the sender email address.
- **To:** email messages are filtered according to the recipient email address.
- **Subject:** email messages are filtered according to the message subject matter.
- **Before date:** email messages are filtered by the sending or receiving date. All messages before the set date are retrieved.
- **After date:** email messages are filtered by the sending or receiving date. All messages after the set date are retrieved.

**Pattern:** press Ctrl+Space to display the list of available values. Select the value to use for each filter.

**Filter condition relation**

Select the type of logical relation you want to use to combine the specified filters:

- **and:** the conditions set by the filters are combined together, the research is more restrictive.
- **or:** the conditions set by the filters are independent, the research is large.

**Global Variables**

**Global Variables**

**ERROR_MESSAGE:** the error message generated by the component when an error occurs. This is an After variable.
and it returns a string. This variable functions only if the Diene errorcheck box is cleared, if the component has this check box.

**NB_EMAIL**: the number of emails received. This is an After variable and it returns an integer.

**CURRENT_FILE**: the current file name. This is a Flow variable and it returns a string.

**CURRENT_FILEPATH**: the current file path. This is a Flow variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

---

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component does not handle data flow, it can be used alone.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>When the Use SSL check box or the imap protocol is selected, tPOP cannot work with IBM Java 6.</td>
</tr>
</tbody>
</table>

---

**Retrieving a selection of email messages from an email server**

This scenario is a one-component Job that retrieves a predefined number of email messages from an email server.

- Drop the **tPOP** component from the **Palette** to the design workspace.
- Double click **tPOP** to display the **Basic settings** view and define the component properties.
- Enter the email server IP address and port number in the corresponding fields.
- Enter the username and password for your email account in the corresponding fields. In this example, the email server is called Free.

---

![Basic settings view for tPOP component](image-url)
In the **Output directory** field, enter the path to the output directory manually, or click the three-dot button next to the field and browse to the output directory where the email messages retrieved from the email server are to be stored.

In the **Filename pattern** field, define the syntax you want to use to name the output files that will hold the messages retrieved from the email server, or press **Ctrl+Space** to display a list of predefined patterns. The syntax used in this example is the following:

```
TalendDate.get Date("yyyyMMdd-hhmmss") + "_" + (counter_tPOP_1 + 1) + ".txt".
```

The output files will be stored as .txt files and are defined by date, time and arrival chronological order.

Clear the **Retrieve all emails?** field and in the **Number of emails to retrieve** field, enter the number of email messages you want to retrieve, 10 in this example.

Select the **Delete emails from server** check box to delete the email messages from the email server once they are retrieved and stored locally.

In the **Choose the protocol** field, select the protocol type you want to use. This depends on the protocol used by the email server. Certain email suppliers, like *Gmail*, use both protocols. In this example, the protocol used is *pop3*.

Save your Job and press **F6** to execute it.

The **tPOP** component retrieves the 10 recent messages from the specified email server.

In the **tPOP** directory stored locally, a .txt file is created for each retrieved message. Each file holds the metadata of the email message headings (sender's address, recipient's address, subject matter) in addition to the message content.
tPostgresPlusBulkExec

Improves performance during Insert operations to a DB2 database.

The tPostgresPlusBulkExec executes the Insert action on the data provided.

The tPostgresPlusOutputBulk and tPostgresPlusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

tPostgresPlusBulkExec Standard properties

These properties are used to configure tPostgresPlusBulkExec running in the Standard Job framework. The Standard tPostgresPlusBulkExec component belongs to the Databases family. The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>

</tr>
<tr>
<td></td>
<td><strong>None</strong>: No operation is carried out.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop and create table</strong>: The table is removed and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table</strong>: The table does not exist and gets created.</td>
</tr>
<tr>
<td></td>
<td><strong>Create table if not exists</strong>: The table is created if it does not exist.</td>
</tr>
<tr>
<td></td>
<td><strong>Drop table if exists and create</strong>: The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td></td>
<td><strong>Clear table</strong>: The table content is deleted.</td>
</tr>
<tr>
<td></td>
<td><strong>Truncate table</strong>: The table content is deleted. You do not have the possibility to rollback the operation.</td>
</tr>
<tr>
<td><strong>File Name</strong></td>
<td>Name of the file to be loaded.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning</strong>: This file is located on the machine specified by the URI in the Host field so it should be on the same machine as the database server.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td></td>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
</tbody>
</table>
|                | • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate
the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

### Advanced settings

<table>
<thead>
<tr>
<th>Additional JDBC Parameters</th>
<th>Specify additional JDBC parameters for the database connection created. This property is not available when the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong> view is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action</strong></td>
<td><strong>Bulk insert</strong> <strong>Bulk update</strong> Depending on the action selected, the required information varies.</td>
</tr>
<tr>
<td><strong>Field terminated by</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This dedicated component offers performance and flexibility of DB2 query handling.</th>
</tr>
</thead>
</table>
| **Dynamic settings** | Click the **[+]** button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independently of Talend Studio.  

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.  

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2446 and **Reading data from different MySQL databases using dynamically loaded connection**. |
Related scenarios

For `tPostgresPlusBulkExec` related topics, see:

- Inserting transformed data in MySQL database on page 2482.
- Truncating and inserting file data into an Oracle database on page 2681.
tPostgresPlusClose

Closes the transaction committed in the connected PostgresPlus database.

tPostgresPlusClose Standard properties

These properties are used to configure tPostgresPlusClose running in the Standard Job framework.
The Standard tPostgresPlusClose component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is to be used along with PostgresPlus components, especially with tPostgresPlusConnection and tPostgresPlusCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
**tPostgresPlusCommit**

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresPlusCommit validates the data processed through the Job into the connected DB.

**tPostgresPlusCommit Standard properties**

These properties are used to configure tPostgresPlusCommit running in the Standard Job framework.

The Standard tPostgresPlusCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

---

**Warning:**
If you want to use a **Row > Main** connection to link tPostgresPlusCommit to your Job, your data will be committed row by row. In this case, do not select the **Close connection** check box or your connection will be closed before the end of your first row commit.

---

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

---

**Usage**

| Usage rule | This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusConnection and tPostgresPlusRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned |
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

### Related scenario

For **tPostgresPlusCommit** related scenario, see Inserting data in mother/daughter tables on page 2426
# tPostgresPlusConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresPlusConnection opens a connection to the database for a current transaction.

## tPostgresPlusConnection Standard properties

These properties are used to configure tPostgresPlusConnection running in the Standard Job framework.

The Standard tPostgresPlusConnection component belongs to the Databases and the ELT families. The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click <strong>Apply.</strong></td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either <strong>Built-in</strong> or <strong>Repository.</strong></td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of database versions.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter your DB authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Use or register a shared DB Connection</strong></td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connections.</td>
</tr>
</tbody>
</table>
connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

## Advanced settings

| **Auto Commit** | Select this check box to commit any changes to the database automatically upon the transaction.  
With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.  
Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed.

For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component. |

| **tStatCatcher Statistics** | Select this check box to gather the job processing metadata at a Job level as well as at each component level. |

## Usage

| **Usage rule** | This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusCommit and tPostgresPlusRollback components. |

## Related scenario

For **tPostgresPlusConnection** related scenario, see **tMysqlConnection** on page 2425.
**tPostgresPlusInput**

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

The tPostgresPlusInput reads a database and extracts fields based on a query.

**tPostgresPlusInput Standard properties**

These properties are used to configure tPostgresPlusInput running in the Standard Job framework.

The Standard tPostgresPlusInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><img src="image" alt="icon" /></td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address.</td>

<tr>
<td>Username and Password</td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>
| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
   • View schema: choose this option to view the schema only.
   • Change to built-in property: choose this option to change the schema to Built-in for local changes.
   • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<p>| Built-in | The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| Repository | The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |</p>
<table>
<thead>
<tr>
<th>Table name</th>
<th>Name of the table to be read.</th>
</tr>
</thead>

</tr>
</tbody>
</table>
The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2446 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 497. For more information on **Dynamic settings** and context variables, see **Talend Studio User Guide**.

### Related scenarios

For related scenarios, see:
tPostgresPlusOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the job.

The tPostgresPlusOutput writes, updates, makes changes or suppresses entries in a database.

tPostgresPlusOutput Standard properties

These properties are used to configure tPostgresPlusOutput running in the Standard Job framework.

The Standard tPostgresPlusOutput component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>

<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
PostgresPlusOutput

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
</tbody>
</table>

**Username and Password**

DB user authentication data.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

**Table**

Name of the table to be written. Note that only one table can be written at a time.

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if already exists and created again.
- **Clear table**: The table content is deleted.
- **Truncate table**: The table content is deleted. You don't have the possibility to rollback the operation.

**Action on data**

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, Job stops.
- **Update**: Make changes to existing entries
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
**Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.

**Delete**: Remove entries corresponding to the input flow.

**Warning:**
It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that:
Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
</tr>
</thead>
<tbody>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)]. |

| Die on error |
| This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a Row > Rejects link. |
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
</table>
| Use alternate schema                         | Select this option to use a schema other than the one specified by the component that establishes the database connection.  
After selecting this option, provide the name of the desired schema in the **Schema** field.  
This option is available when **Use an existing connection** is selected in **Basic settings** view. |
| Additional JDBC Parameters                   | Specify additional JDBC parameters for the database connection created.  
This property is not available when the **Use an existing connection** check box in the **Basic settings** view is selected. |
| Commit every                                 | Enter the number of rows to be completed before committing batches of rows together into the DB.  
This option ensures transaction quality (but not rollback) and, above all, better performance at execution. |
| Additional Columns                           | This option is not offered if you create (with or without drop) the DB table.  
This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.  
**Name**: Type in the name of the schema column to be altered or inserted as new column  
**SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.  
**Position**: Select **Before**, **Replace** or **After** following the action to be performed on the reference column.  
**Reference column**: Type in a column of reference that the **tDBOutput** can use to place or replace the new or altered column. |
| Use field options                            | Select this check box to customize a request, especially when there is double action on data. |
| Debug query mode                             | Select this check box to display each step during processing entries in a database. |
| Support null in **"SQL WHERE"** statement    | Select this check box if you want to deal with the Null values contained in a DB table.  
**Note**:  
Ensure that the Nullable check box is selected for the corresponding columns in the schema. |
| Use Batch                                    | Select this check box to activate the batch mode for data processing. |
**Note:**
This check box is available only when you have selected the **Insert**, the **Update** or the **Delete** option in the **Action on data** field.

<table>
<thead>
<tr>
<th><strong>Batch Size</strong></th>

**Global Variables**

| **Global Variables** | **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.  
**NB_LINE_UPDATED**: the number of rows updated. This is an After variable and it returns an integer.  
**NB_LINE_INSERTED**: the number of rows inserted. This is an After variable and it returns an integer.  
**NB_LINE_DELETED**: the number of rows deleted. This is an After variable and it returns an integer.  
**NB_LINE_REJECTED**: the number of rows rejected. This is an After variable and it returns an integer.  
**QUERY**: the query statement processed. This is an After variable and it returns a string.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see *Talend Studio User Guide*.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |

**Usage**

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible. This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a PostgresPlus database. It also allows you to create a reject flow using a <strong>Row &gt; Rejects</strong> link to filter data in error. For an example of <strong>tMySqlOutput</strong> in use, see <em>Retrieving data in error with a Reject link</em> on page 2474.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Dynamic settings</strong></th>
<th>Click the <strong>[]</strong> button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in</th>
</tr>
</thead>
</table>
different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For tPostgresPlusOutput related topics, see:

- Inserting a column and altering data using tMysqlOutput on page 2466.
tPostgresPlusOutputBulk

Prepares the file to be used as parameter in the INSERT query to feed the PostgresPlus database.

The tPostgresPlusOutputBulk writes a file with columns based on the defined delimiter and the PostgresPlus standards.

The tPostgresPlusOutputBulk and tPostgresPlusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component, detailed in a separate section. The advantage of using two separate components is that the data can be transformed before it is loaded in the database.

tPostgresPlusOutputBulk Standard properties

These properties are used to configure tPostgresPlusOutputBulk running in the Standard Job framework.

The Standard tPostgresPlusOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

</table>
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th>Built-In: You create and store the schema locally for this component only.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
</tr>
</tbody>
</table>

### Advanced settings

| Row separator | String (ex: "\n" on Unix) to distinguish rows. |
|---|
| Field separator | Character, string or regular expression to separate fields. |
| Include header | Select this check box to include the column header to the file. |
| Encoding | Select the encoding from the list or select **Custom** and define it manually. This field is compulsory for DB data handling. |

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it. For further information about variables, see <strong>Talend Studio User Guide</strong>. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</th>
</tr>
</thead>
</table>
Usage

| Usage rule | This component is to be used along with tPostgresPlusBulkExec component. Used together they offer gains in performance while feeding a PostgresPlus database. |

Related scenarios

For use cases in relation with tPostgresPlusOutputBulk, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
### tPostgresPlusOutputBulkExec

Improves performance during Insert operations to a PostgresPlus database.

The tPostgresPlusOutputBulkExec executes the Insert action on the data provided.

The tPostgresPlusOutputBulk and tPostgresplusBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresPlusOutputBulkExec component.

### tPostgresPlusOutputBulkExec Standard properties

These properties are used to configure tPostgresPlusOutputBulkExec running in the Standard Job framework.

The Standard tPostgresPlusOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

#### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property type</strong></td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td><strong>Built-in</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>DB Version</strong></td>
<td>List of database versions.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address. Currently, only localhost, 127.0.0.1 or the exact IP address of the local machine is allowed for proper functioning. In other words, the database server must be installed on the same machine where the Studio is installed or where the Job using tPostgresPlusOutputBulkExec is deployed.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
Table

Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

Action on table

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create a table**: The table is removed and created again.
- **Create a table**: The table does not exist and gets created.
- **Create a table if not exists**: The table is created if it does not exist.
- **Clear a table**: The table content is deleted.

File Name

Name of the file to be generated and loaded.

**Warning:**

This file is generated on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server.

Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded onto the database.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th>Limitation</th>
<th>The database server must be installed on the same machine where the Studio is installed or where the Job using tPostgresPlusOutputBulkExec is deployed, so that the component functions properly.</th>
</tr>
</thead>
</table>

### Related scenarios

For use cases in relation with tPostgresPlusOutputBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tPostgresPlusRollback

Avoids to commit part of a transaction involuntarily.
The tPostgresPlusRollback cancels the transaction committed in the connected DB.

tPostgresPlusRollback Standard properties

These properties are used to configure tPostgresPlusRollback running in the Standard Job framework.
The Standard tPostgresPlusRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresPlusConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tPostgresPlus* components, especially with the tPostgresPlusConnection and tPostgresPlusCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different... |
Related scenarios

For tPostgresPlusRollback related scenario, see Rollback from inserting data in mother/daughter tables on page 2429.
tPostgresPlusRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresPlusRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output.

**tPostgresPlusRow Standard properties**

These properties are used to configure tPostgresPlusRow running in the Standard Job framework.

The Standard tPostgresPlusRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-in:</strong> No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide*.

**Table name**

Name of the table to be read.

**Query type**

Either **Built-in** or **Repository**.

- **Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.
- **Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

**Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Die on error**

This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-
free rows. If needed, you can retrieve the rows on error via a Row > Rejects link.

### Advanced settings

<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection created. This property is not available when the Use an existing connection check box in the Basic settings view is selected.</td>
</tr>
</tbody>
</table>
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the use column list.  
**Note:** This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the Set PreparedStatement Parameter table, define the parameters represented by “?” in the SQL instruction of the Query field in the Basic Settings tab.  
- **Parameter Index**: Enter the parameter position in the SQL instruction.  
- **Parameter Type**: Enter the parameter type.  
- **Parameter Value**: Enter the parameter value.  
**Note:** This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
</table>
| **QUERY** | the query statement processed. This is an After variable and it returns a string. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

## Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the DB query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

## Related scenarios

- Combining two flows for selective output on page 2503
- Procedure on page 622.
- Removing and regenerating a MySQL table index on page 2497.
**tPostgresPlusSCD**

Addresses Slowly Changing Dimension needs, reading regularly a source of data and logging the changes into a dedicated SCD table.

The tPostgresPlusSCD reflects and tracks changes in a dedicated MSSQL SCD table.

**tPostgresPlusSCD Standard properties**

These properties are used to configure tPostgresPlusSCD running in the Standard Job framework.

The Standard tPostgresPlusSCD component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

<table>
<thead>
<tr>
<th>Property type</th>
<th>Either <strong>Built-in</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
</table>

**Built-in:** No property data stored centrally.

**Repository:** Select the Repository file where Properties are stored. The following fields are pre-filled in using fetched data.

<table>
<thead>
<tr>
<th>DB Version</th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Server</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td>----------</td>
<td>-----------------------------------</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the DB schema.</td>
</tr>
</tbody>
</table>
| **Username and Password** | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |
| **Table** | Name of the table to be written. Note that only one table can be written at a time. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| **Built-in**: The schema is created and stored locally for this component only. Related topic: see Talend Studio User Guide. |
| **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see Talend Studio User Guide. |
| **SCD Editor** | The SCD editor helps to build and configure the data flow for slowly changing dimension outputs.  
For more information, see SCD management methodology on page 2511. |
| **Use memory saving Mode** | Select this check box to maximize system performance. |
| **Source keys include Null** | Select this check box to allow the source key columns to have Null values.  
**Warning:**  
Special attention should be paid to the uniqueness of the source key(s) values when this option is selected. |
### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC parameters for the database connection created. This property is not available when the <a href="#">Use an existing connection</a> check box in the <a href="#">Basic settings</a> view is selected.</td>

**Use SCD Type 1 fields**

Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

**Use SCD Type 2 fields**

Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

**SCD type 2 fields**

Click the `[+]` button to add as many rows as needed, each row for a column. Click the arrow on the right side of the cell and select the column whose value changes will be tracked using Type 2 SCD from the drop-down list displayed.

This table is available only when the **Use SCD type 2 fields** option is selected.

**Start date**

Specify the column that holds the start date for type 2 SCD. This list is available only when the **Use SCD type 2 fields** option is selected.

**End date**

Specify the column that holds the end date for type 2 SCD. This list is available only when the **Use SCD type 2 fields** option is selected.

**Log active status**

Select this check box and from the **Active field** drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD. This option is available only when the **Use SCD type 2 fields** option is selected.

**Log versions**

Select this check box and from the **Version field** drop-down list displayed, select the column that holds the version number of the record for type 2 SCD. This option is available only when the **Use SCD type 2 fields** option is selected.

**Note:** To avoid duplicated change records, it is recommended to select a column that can identify each change for this field.
## Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional JDBC parameters for the database connection created. This property is not available when the <strong>Use an existing connection</strong> check box in the <strong>Basic settings</strong> view is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Debug mode</strong></td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

## Global Variables

<table>
<thead>
<tr>
<th><strong>ERROR_MESSAGE</strong></th>
<th>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the <strong>Die on error</strong> check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press <strong>Ctrl + Space</strong> to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see <strong>Talend Studio User Guide</strong>.</td>
</tr>
</tbody>
</table>

## Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component is used as an output component. It requires an input component and Row main link as input.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Dynamic settings</strong></td>
<td>Click the [*] button to add a row in the table and fill the <strong>Code</strong> field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The <strong>Dynamic settings</strong> table is available only when the <strong>Use an existing connection</strong> check box is selected in the <strong>Basic settings</strong> view. Once a dynamic parameter is defined, the <strong>Component List</strong> box in the <strong>Basic settings</strong> view becomes unusable. For examples on using dynamic parameters, see <strong>Reading data from databases through context-based dynamic connections</strong> on page 2446 and <strong>Reading data from different MySQL databases using dynamically loaded connection parameters</strong> on page 497. For more information on <strong>Dynamic settings</strong> and context variables, see <strong>Talend Studio User Guide</strong>.</td>

Related Scenarios

For related scenarios, see:

- Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1879.
- Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component on page 2948.
**tPostgresqlBulkExec**

Improves performance while carrying out the Insert operations to a Postgresql database.

The tPostgresqlBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are used together to first output the file that will be then used as parameter to execute the SQL query stated. These two steps compose the tPostgresqlOutputBulkExec component, detailed in a separate section. The interest in having two separate elements lies in the fact that it allows transformations to be carried out before the data loading in the database.

**tPostgresqlBulkExec Standard properties**

These properties are used to configure tPostgresqlBulkExec running in the Standard Job framework.

The Standard tPostgresqlBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository</td>
</tr>
<tr>
<td></td>
<td>Built-in: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th>List of database versions.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong></td>
<td>Database server IP address</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of DB server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  *None*: No operation is carried out.  
  *Drop and create table*: The table is removed and created again.  
  *Create table*: The table does not exist and gets created.  
  *Create table if not exists*: The table is created if it does not exist.  
  *Drop table if exists and create*: The table is removed if it already exists and created again.  
  *Clear table*: The table content is deleted.  
  *Truncate table*: The table content is deleted. You don not have the possibility to rollback the operation. |
| **File Name**  | Name of the file to be loaded. |
| **Warning**: This file is located on the machine specified by the URI in the **Host** field so it should be on the same machine as the database server. |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.  
  Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  *View schema*: choose this option to view the schema only.  
  *Change to built-in property*: choose this option to change the schema to **Built-in** for local changes.  
  *Update repository connection*: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the |
Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

**Built-In:** You create and store the schema locally for this component only.

**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>
Usage

Usage rule

This component is to be used along with tPostgresqlOutPutBulk component. Used together, they can offer gains in performance while feeding a Postgresql database.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

For use cases in relation with tPostgresqlBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
**tPostgresqlClose**

Closes the transaction committed in the connected Postgresql database.

**tPostgresqlClose Standard properties**

These properties are used to configure tPostgresqlClose running in the Standard Job framework.

The Standard tPostgresqlClose component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Postgresql components, especially with tPostgresqlConnection and tPostgresqlCommit. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Related scenarios

No scenario is available for the Standard version of this component yet.
**tPostgresqlCommit**

Commits in one go a global transaction, using a unique connection, instead of doing that on every row or every batch and thus improves performance.

The tPostgresqlCommit validates the data processed through the Job into the connected DB

**tPostgresqlCommit Standard properties**

These properties are used to configure tPostgresqlCommit running in the Standard Job framework.

The Standard tPostgresqlCommit component belongs to the Databases family.

The component in this framework is available in all Talend products.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**

*If you want to use a Row > Main connection to link tPostgresqlCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.*

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tPostgresql" components, especially with the tPostgresqlConnection and tPostgresqlRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned |
in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For tPostgresqlCommit related scenario, see Inserting data in mother/daughter tables on page 2426.
tPostgresqlConnection

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.

The tPostgresqlConnection opens a connection to the database for a current transaction.

**tPostgresqlConnection Standard properties**

These properties are used to configure tPostgresqlConnection running in the Standard Job framework.

The Standard tPostgresqlConnection component belongs to the Databases and the ELT families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong></td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of database versions.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td>Use or register a shared DB Connection</td>
<td>Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the <strong>Shared DB Connection Name</strong> field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.</td>
</tr>
</tbody>
</table>
This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the **tRunJob** component. Using a shared connection together with a **tRunJob** component with either of these two options enabled will cause your Job to fail.

This check box is not available when the **Specify a data source alias** check box is selected.

<table>
<thead>
<tr>
<th>Specify a data source alias</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box and specify the alias of a data source created on the <strong>Talend Runtime</strong> side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in <strong>Talend Runtime</strong>.</td>
</tr>
<tr>
<td>This check box is not visible when the <strong>Use or register a shared DB Connection</strong> check box is selected.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>Data source alias</th>
</tr>

**Advanced settings**

<table>
<thead>
<tr>
<th>Auto Commit</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to commit any changes to the database automatically upon the transaction.</td>
</tr>
<tr>
<td>With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.</td>
</tr>
<tr>
<td>Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is more commonly used with other <strong>tPostgresql</strong> components, especially with the <strong>tPostgresqlCommit</strong> and <strong>tPostgresqlRollback</strong> components.</td>
</tr>
</tbody>
</table>

**Related scenario**

For **tPostgresqlConnection** related scenario, see **tMysqlConnection** on page 2425
**tPostgresqlInput**

Executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component via a Main row link.

The tPostgresqlInput reads a database and extracts fields based on a query.

**tPostgresqlInput Standard properties**

These properties are used to configure tPostgresqlInput running in the Standard Job framework.

The Standard tPostgresqlInput component belongs to the Databases family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in: No property data stored centrally.</td>
<td></td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
</tbody>
</table>

![Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.](image)

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
</table>
Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

| **DB Version** | List of database versions. |
| **Host** | Database server IP address |
| **Port** | Listening port number of DB server. |
| **Database** | Name of the database |
| **Schema** | Exact name of the schema. |
| **Username and Password** | DB user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.
**Table name**

Name of the table to be read.

**Query type and Query**

Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.

**Specify a data source alias**

Select this check box and specify the alias of a data source created on the *Talend Runtime* side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in *Talend Runtime*.

This check box is not available when the **Use an existing connection** check box is selected.

**Data source alias**

Enter the alias of the data source created on the *Talend Runtime* side.

This field is available only when the **Specify a data source alias** check box is selected.

### Advanced settings

**Additional JDBC Parameters**

Specify additional JDBC parameters for the database connection created.

This property is not available when the **Use an existing connection** check box in the **Basic settings** view is selected.

**Use fetch size**

Select this check box and in the **Fetch size** field displayed, specify the number of rows to work with at a time to improve the performance.

**Trim all the String/Char columns**

Select this check box to remove leading and trailing whitespace from all the String/Char columns.

**Trim column**

Remove leading and trailing whitespace from defined columns.

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**Global Variables**

- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
- **QUERY**: the query statement being processed. This is a Flow variable and it returns a string.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for Postgresql databases.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

</tr>
<tr>
<td><strong>Action on data</strong></td>
</tr>
</tbody>
</table>
### Update or insert

Update the record with the given reference. If the record does not exist, a new record would be inserted.

### Delete

Remove entries corresponding to the input flow.

---

**Warning:** It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.

---

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

---

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

---

### Use spatial options

**Note:** This check box is available when you selected the table creation related option from the Action on table list.

Select this check box to use the PostgreSQL database as a spatial database for geographic information system (GIS). When this check box is selected, two other check boxes are displayed.
- **Create Spatial index**: select this check box to create spatial index.
- **Create geometry columns reference**: select this check box to create geometry columns reference.

For more information about the PostgreSQL database, see [http://www.postgresql.org/about/](http://www.postgresql.org/about/).

### Specify a data source alias
Select this check box and specify the alias of a data source created on the Talend Runtime side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in Talend Runtime.

This check box is not available when the **Use an existing connection** check box is selected.

### Data source alias
Enter the alias of the data source created on the Talend Runtime side.

This field is available only when the **Specify a data source alias** check box is selected.

### Die on error
This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

#### Use alternate schema
Select this option to use a schema other than the one specified by the component that establishes the database connection (that is, the component selected from the Component list drop-down list in Basic settings view). After selecting this option, provide the name of the desired schema in the Schema field.

This option is available when **Use an existing connection** is selected in Basic settings view.

#### Additional JDBC Parameters
Specify additional JDBC parameters for the database connection created.

This property is not available when the **Use an existing connection** check box in the Basic settings view is selected.

#### Commit every
Enter the number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.

#### Additional Columns
This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

- **Name**: Type in the name of the schema column to be altered or inserted as new column
- **SQL expression**: Type in the SQL statement to be executed in order to alter or insert the relevant column data.
<table>
<thead>
<tr>
<th><strong>Position</strong></th>
<th>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Reference column</strong></td>
<td>Type in a column of reference that the tDBOutput can use to place or replace the new or altered column.</td>
</tr>
</tbody>
</table>
| **Use save point** | Select this check box to use savepoints in the transaction. This check box will not be available if you select:  
  • the **Die on error** check box in the **Basic settings** view, or  
  • the **Use Batch Size** check box in the **Advanced settings** view.  
This check box will not work if you:  
  • type in 0 in the **Commit every** field, or  
  • select the **Use an existing connection** check box in the **Basic settings** view while the **Auto Commit** mode is activated in the database connection component. |
| **Use field options** | Select this check box to customize a request, especially when there is double action on data. |
| **Debug query mode** | Select this check box to display each step during processing entries in a database. |
| **Support null in **SQL WHERE** statement** | Select this check box if you want to deal with the Null values contained in a DB table.  
**Note:** Ensure that the Nullable check box is selected for the corresponding columns in the schema. |
| **Convert columns and table to lowercase** | Select this check box to automatically convert the letters in all the column names and the table name to lowercase when you manipulate a table (such as inserting, deleting, or updating a table). |
| **Use Batch** | Select this check box to activate the batch mode for data processing.  
**Note:** This check box is available only when you have selected the **Insert**, the **Update** or the **Delete** option in the **Action on data** field. |
| **Batch Size** | Specify the number of records to be processed in each batch.  
This field appears only when the **Use batch mode** check box is selected. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

**Global Variables**

| **Global Variables** | **NB_LINE:** the number of rows processed. This is an After variable and it returns an integer.  
**NB_LINE_UPDATED:** the number of rows updated. This is an After variable and it returns an integer. |
Usage

Usage rule

This component offers the flexibility benefit of the DB query and covers all of the SQL queries possible.

This component must be used as an output component. It allows you to carry out actions on a table or on the data of a table in a Postgresql database. It also allows you to create a reject flow using a Row > Rejects link to filter data in error. For an example of tMySqlOutput in use, see Retrieving data in error with a Reject link on page 2474.

Dynamic settings

Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the
Related scenarios

For **tPostgresqlOutput** related topics, see:

- Inserting a column and altering data using **tMysqlOutput** on page 2466.
tPostgresqlOutputBulk

Prepares the file to be used as parameters in the INSERT query to feed the Postgresql database.

The tPostgresqlOutputBulk writes a file with columns based on the defined delimiter and the Postgresql standards.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component, detailed in a separate section. The advantage of having two separate steps is that it makes it possible to transform data before it is loaded in the database.

tPostgresqlOutputBulk Standard properties

These properties are used to configure tPostgresqlOutputBulk running in the Standard Job framework.

The Standard tPostgresqlOutputBulk component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

| Database | Select a type of database from the list and click Apply. |
| Property type | Either Built-in or Repository |
| Built-in: No property data stored centrally. |
| Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved. |
| File Name | Name of the file to be generated. |
| Warning: This file is generated on the local machine or a shared folder on the LAN. |
| Append | Select this check box to add the new rows at the end of the file. |
| Schema and Edit Schema | A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either Built-in or stored remotely in the Repository. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available: |
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Row separator</strong></th>
<th>String (ex: &quot;\n&quot; on Unix) to distinguish rows.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Field separator</strong></td>
<td>Character, string or regular expression to separate fields.</td>
</tr>
<tr>
<td><strong>Include header</strong></td>
<td>Select this check box to include the column header to the file.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select the encoding from the list or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

- **Global Variables**

  - **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.
  - **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.
For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is to be used along with tPostgresqlBulkExec component. Used together they offer gains in performance while feeding a Postgresql database. |

Related scenarios

For use cases in relation with tPostgresqlOutputBulk, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tPostgresqlOutputBulkExec

Improves performance during Insert operations to a Postgresql database.

The tPostgresqlOutputBulkExec executes the Insert action on the data provided.

The tPostgresqlOutputBulk and tPostgresqlBulkExec components are generally used together as part of a two step process. In the first step, an output file is generated. In the second step, this file is used in the INSERT operation used to feed a database. These two steps are fused together in the tPostgresqlOutputBulkExec component.

**tPostgresqlOutputBulkExec Standard properties**

These properties are used to configure tPostgresqlOutputBulkExec running in the Standard Job framework.

The Standard tPostgresqlOutputBulkExec component belongs to the Databases family.

The component in this framework is available in all Talend products.

*Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.*

<td></td>
</tr>
</tbody>
</table>
**Table**

Name of the table to be written. Note that only one table can be written at a time and that the table must exist for the insert operation to succeed.

**Action on table**

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if already exists and created again.
- **Clear a table**: The table content is deleted.

**File Name**

Name of the file to be generated and loaded.

**Warning:**

This file is generated on the machine specified by the URI in the **Host** field and it should be on the same machine as the database server.

**Schema and Edit Schema**

A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.
You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Related scenarios

For use cases in relation with `tPostgresqlOutputBulkExec`, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tPostgresqlRollback

Avoids to commit part of a transaction involuntarily.
The tPostgresqlRollback cancels the transaction commit in the connected DB.

tPostgresqlRollback Standard properties

These properties are used to configure tPostgresqlRollback running in the Standard Job framework.
The Standard tPostgresqlRollback component belongs to the Databases family.
The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tPostgresqlConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tPostgresql* components, especially with the tPostgresqlConnection and tPostgresqlCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection. |
## Related scenario

For **tPostgresqlRollback** related scenario, see **tMysqlRollback** on page 2491.
tPostgresqlRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database. The SQLBuilder tool helps you write easily your SQL statements.

The tPostgresqlRow is the specific component for the database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it doesn't provide output.

tPostgresqlRow Standard properties

These properties are used to configure tPostgresqlRow running in the Standard Job framework.

The Standard tPostgresqlRow component belongs to the Databases family.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

| Database | Select a type of database from the list and click Apply. |
| Property type | Either Built-in or Repository. |
| Built-in | No property data stored centrally. |
| Repository | Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved. |

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>DB Version</strong></th>
<th><strong>List of database versions.</strong></th>
</tr>

<td><strong>Listening port number of DB server.</strong></td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td><strong>Name of the database.</strong></td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td><strong>Name of the schema.</strong></td>
</tr>
</tbody>
</table>
| **Username and Password** | **DB user authentication data.**  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Schema and Edit Schema** | **A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The schema is either **Built-in** or stored remotely in the **Repository**.**  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema**: choose this option to view the schema only.  
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.**  |
<p>| <strong>Built-In</strong>   | <strong>You create and store the schema locally for this component only.</strong> |
| <strong>Repository</strong> | <strong>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</strong> |
| <strong>Query type</strong> | <strong>Either <strong>Built-in</strong> or <strong>Repository</strong>.</strong> |
| <strong>Built-in</strong>   | <strong>Fill in manually the query statement or build it graphically using SQLBuilder.</strong> |
| <strong>Repository</strong> | <strong>Select the relevant query stored in the Repository. The Query field gets accordingly filled in.</strong> |
| <strong>Query</strong>      | <strong>Enter your DB query paying particularly attention to properly sequence the fields in order to match the schema definition.</strong> |
| <strong>Specify a data source alias</strong> | <strong>Select this check box and specify the alias of a data source created on the <strong>Talend Runtime</strong> side to use the shared connection pool defined in the data source configuration. This option works only when you deploy and run your Job in <strong>Talend Runtime</strong>.</strong> |</p>
<table>
<thead>
<tr>
<th><strong>PostgresqlRow</strong></th>
<th>This check box is not available when the <strong>Use an existing connection</strong> check box is selected.</th>
</tr>
</thead>
</table>
| **Data source alias** | Enter the alias of the data source created on the **Talend Runtime** side.  
This field is available only when the **Specify a data source alias** check box is selected. |
| **Die on error** | This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error via a **Row > Rejects** link. |

**Advanced settings**

| **Additional JDBC Parameters** | Specify additional JDBC parameters for the database connection created.  
This property is not available when the **Use an existing connection** check box in the **Basic settings** view is selected. |
| **Propagate QUERY’s recordset** | Select this check box to insert the result of the query into a **COLUMN** of the current flow. Select this column from the **use column** list.  
**Note:**  
This option allows the component to have a different schema from that of the preceding component.  
Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by **tParseRecordSet**. |
| **Use PreparedStatement** | Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by “?” in the SQL instruction of the **Query** field in the **Basic Settings** tab.  
**Parameter Index**: Enter the parameter position in the SQL instruction.  
**Parameter Type**: Enter the parameter type.  
**Parameter Value**: Enter the parameter value.  
**Note:**  
This option is very useful if you need to execute the same query several times. Performance levels are increased |
| **Commit every** | Number of rows to be completed before committing batches of rows together into the DB. This option ensures transaction quality (but not rollback) and above all better performance on executions. |
| **tStat Catcher Statistics** | Select this check box to collect log data at the component level. |

<td>List of database versions.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th>Port</th>
<th>Listening port number of DB server.</th>
</tr>
</thead>
<tbody>
<tr>

<td></td>
</tr>
</tbody>
</table>
PostgresqlSCD

s database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

| Limitation | This component does not support using SCD type 0 together with other SCD types. |

**Related scenario**

For related topics, see tMysqlSCD on page 2508.
tPostgresqlSCDELT

Addresses Slowly Changing Dimension needs through SQL queries (server-side processing mode), and logs the changes into a dedicated DB2 SCD table.

The tPostgresqlSCDELT reflects and tracks changes in a dedicated Postgresql SCD table.

**tPostgresqlSCDELT Standard properties**

These properties are used to configure tPostgresqlSCDELT running in the Standard Job framework.

The Standard tPostgresqlSCDELT component belongs to the Business Intelligence and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-in:</strong> No property data stored centrally. Enter properties manually.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> Select the repository file where Properties are stored. The fields that come after are pre-filled in using the fetched data.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>DB Version</td>
<td>List of database versions.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
### Host
The IP address of the database server.

### Port
Listening port number of database server.

### Database
Name of the database

### Username and Password
User authentication data for a dedicated database.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Source table
Name of the input DB2 SCD table.

### Table
Name of the table to be written. Note that only one table can be written at a time.

### Action on table
Select to perform one of the following operations on the table defined:
- **None**: No action carried out on the table.
- **Drop and create table**: The table is removed and created again
- **Create table**: A new table gets created.
- **Create table if not exists**: A table gets created if it does not exist.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.
- **Truncate table**: The table content is deleted. You do not have the possibility to rollback the operation.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word *line* when naming the fields.
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

- **Built-in**: The schema is created and stored locally for this component only. Related topic: see *Talend Studio User Guide.*

- **Repository**: The schema already exists and is stored in the Repository, hence can be reused. Related topic: see *Talend Studio User Guide.*
### Surrogate Key
Select the surrogate key column from the list.

### Creation
Select the method to be used for the surrogate key generation.

For more information regarding the creation methods, see SCD management methodology on page 2511.

### Source Keys
Select one or more columns to be used as keys, to ensure the unicity of incoming data.

### Use SCD Type 1 fields
Use type 1 if tracking changes is not necessary. SCD Type 1 should be used for typos corrections for example. Select the columns of the schema that will be checked for changes.

### Use SCD Type 2 fields
Use type 2 if changes need to be tracked down. SCD Type 2 should be used to trace updates for example. Select the columns of the schema that will be checked for changes.

### SCD type 2 fields
Click the [+] button to add as many rows as needed, each row for a column. Click the arrow on the right side of the cell and select the column whose value changes will be tracked using Type 2 SCD from the drop-down list displayed.

This table is available only when the Use SCD type 2 fields option is selected.

### Start date
Specify the column that holds the start date for type 2 SCD.

This list is available only when the Use SCD type 2 fields option is selected.

### End date
Specify the column that holds the end date for type 2 SCD.

This list is available only when the Use SCD type 2 fields option is selected.

**Note:** To avoid duplicated change records, it is recommended to select a column that can identify each change for this field.

### Log active status
Select this check box and from the Active field drop-down list displayed, select the column that holds the true or false status value, which helps to spot the active record for type 2 SCD.

This option is available only when the Use SCD type 2 fields option is selected.

### Log versions
Select this check box and from the Version field drop-down list displayed, select the column that holds the version number of the record for type 2 SCD.

This option is available only when the Use SCD type 2 fields option is selected.

### Advanced settings

| Additional JDBC Parameters | Specify additional JDBC parameters for the database connection created. |
This property is not available when the **Use an existing connection** check box in the **Basic settings** view is selected.

<table>
<thead>
<tr>
<th>Debug mode</th>
<th>Select this check box to display each step during processing entries in a database.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tStat Catcher Statistics</strong></td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

## Global Variables

### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

## Usage

### Usage rule

This component is used as an output component. It requires an input component and Row main link as input.

### Dynamic settings

Click the [+] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2446 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 497. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).
Tracking data changes in a PostgreSQL table using the tPostgreSQLSCDELT component

This scenario describes a Job that captures the employee data changes in a PostgreSQL table using SCD (Slowly Changing Dimensions) Type 1 and Type 2 methods implemented by the tPostgreSQLSCDELT component, and writes both the current and historical data in a SCD dimension table.

The input data contains various employee details including name, role, salary, and another id column is added to help ensuring the unicity of the input data.

At first, the following employee data is inserted to a new Snowflake table.

<table>
<thead>
<tr>
<th>#id; name; role; salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1; Mark Smith; tester; 11000.00</td>
</tr>
<tr>
<td>2; Thomas Johnson; developer; 12000.00</td>
</tr>
<tr>
<td>3; Teddy Brown; tester; 13000.00</td>
</tr>
</tbody>
</table>

Later, the table is updated with the following renewed employee data.

<table>
<thead>
<tr>
<th>#id; name; role; salary</th>
</tr>
</thead>
<tbody>
<tr>
<td>1; Mark Smith; tester; 15000.00</td>
</tr>
<tr>
<td>2; Thomas Johnson; tester; 18000.00</td>
</tr>
<tr>
<td>3; Teddy Brown; writer; 17000.00</td>
</tr>
<tr>
<td>4; John Clinton; developer; 19000.00</td>
</tr>
</tbody>
</table>

You can see the role of Thomas Johnson is changed from developer to tester, the role of Teddy Brown is changed from tester to writer, and his salary is raised from 13000.00 to 17000.00. Besides, a new employee record with id 4 is inserted. In this scenario,

- the existing name and role data will be overwritten by the new data, so SCD Type 1 method will be performed on them, and
- the full history of the salary data will be retained, and a new record with the changed data will be always created and the previous record will be closed, so SCD Type 2 method will be performed on it.

For more information about SCD types, see SCD management methodology on page 2511.

Creating a Job for tracking data changes in a PostgreSQL table using tPostgresqlSCDELT

Procedure

1. Create a new Job and add a tPostgreSQLConnection component, a tCreateTable component, two tFixedFlowInput components, two tPostgreSQL Input components, two tPostgreSQLOutput components, two tPostgresqlSCDELT components, and two tLogRow components to the Job.
2. Link the first `FixedFlowInput` component to the first `PostgreSQLOutput` component using a Row > Main connection.

3. Do the same to link the first `PostgreSQLInput` component to the first `LogRow` component, the second `FixedFlowInput` component to the second `PostgreSQLOutput` component, and the second `PostgreSQLInput` component to the second `LogRow` component.

4. Link the `PostgreSQLConnection` component to the `CreateTable` component using a Trigger > On Subjob Ok connection.

5. Do the same to link the first `FixedFlowInput` component to the first `PostgreSQLSCDELT` component, the first `PostgreSQLSCDELT` component to the first `PostgreSQLInput` component, the first `PostgreSQLInput` component to the second `FixedFlowInput` component, the second `FixedFlowInput` component to the second `PostgreSQLSCDELT` component, the second `PostgreSQLSCDELT` component to the second `PostgreSQLInput` component, and the second `PostgreSQLInput` component to the second `PostgreSQLSCDELT` component.

Opening a connection to a PostgreSQL database
Procedure

1. Double-click the tPostgreSQLConnection component to open its Basic settings view.

![Image of tPostgreSQLConnection](image-url)

2. In the Host, Port, Database, Schema, Username, and Password fields, enter the information required for the connection to the PostgreSQL database.

Creating a PostgreSQL table

Procedure

1. Double-click the tCreateTable component to open its Basic settings view.

![Image of tCreateTable](image-url)

2. In the Basic settings view, and from the Database Type list, select Postgresql for this scenario.

3. Select the Use an existing connection check box and from the Component List drop-down list displayed, select the connection component to reuse the connection created by it, tPostgreSQLConnection_1 in this example.

4. In the Table Name field, fill in a name for the table to be created, employee in this example.

5. From the Table Action list, select Create table if not exist.

6. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding four columns: id of Integer type as the primary key, name and role of String type, and salary of Double type.

In the end, a new table employee is created to store the employee data.
Inserting data into the new PostgreSQL table

Procedure

1. Double-click the first `tFixedFlowInput` component to open its Basic settings view.

2. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema by adding four columns: id of Integer type as the primary key, name and role of String type, and salary of Double type.

3. Click OK to save the schema changes. In the pop-up dialog box, click Yes to propagate the schema to the next component.
4. Select Use Inline Content in the Mode area. Then in the Content field displayed, enter the following employee data to be inserted.

   1;Mark Smith;tester;11000.00
   2;Thomas Johnson;developer;12000.00
   3;Teddy Brown;tester;13000.00

5. Double-click the first tPostgreSQLOutput component to open its Basic settings view.

6. Select the Use an existing connection check box and from the Component List drop-down list displayed, and then select the connection component to reuse the connection created by it, tPostgreSQLConnection_1 in this example.

7. In the Table field, enter the name of the table into which the employee data will be written, employee in this example.

8. In the Action on table drop-down list, select Default.

9. In the Action on data drop-down list, select Insert to insert the employee data transferred from the first tFixedFlowInput component.

10. Click the [...] button next to Edit schema to check whether the schema of tPostgreSQLOutput is the same as the schema of tFixedFlowInput.

Tracking inserted data changes and writing the changes into a SCD dimension table

Procedure

1. Double-click the first tPostgreSQLSCDELT component to open its Basic settings view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

3. In the **Source table** field, enter the name of the table whose data changes will be captured, `employee` in this example.

4. In the **Table** field, enter the name of the SCD dimension table that will store both the current and historical employee data, `employee_scd` in this example.

5. Select **Create table** from the **Action on table** drop-down list to create the SCD dimension table.

6. Click the [...] button next to **Edit schema** and in the pop-up dialog box, define the schema by adding nine columns: `sk` (as the primary key) and `id` of Integer type, `name` and `role` of String type, `salary` of Double type, `start_date` and `end_date` of Date type with the Date Pattern `dd-MM-yyyy`, and `active_status` and `version` of Integer type. When done, click **OK** to save the changes and close the dialog box.
7. From the **Surrogate key** drop-down list, select the name of the column that will be used as the primary key of the SCD dimension table, `sk` in this example.

8. Select **DB sequence** from the **Creation** drop-down list and in the **Sequence** field displayed, enter the name of the PostgreSQL sequence used to generate the surrogate key for the SCD Type 2 method, `employee_sequence` in this example.

9. Click the `[+]` button below the **Source keys** table to add a new line, and click the **Name** cell and select the key column of the source table from the drop-down list, `id` in this example.

10. Select the **Use SCD type 1 fields** check box, click the `[+]` button below the **SCD type 1 fields** table twice to add two lines. Then click each cell and from the drop-down list, select the column on which the SCD Type 1 method will be performed. In this example, they are `name` and `role`.

11. Select the **Use SCD type 2 fields** check box, click the `[+]` button below the **SCD type 2 fields** table to add a line. Then click the cell and select the column on which the SCD Type 2 method will be performed. In this example, it is `salary`.

12. From the **Start date** and **End date** drop-down lists, select the columns used to hold the start date and end date values for the SCD Type 2 method respectively, `start_date` and `end_date` in this example.

13. Select the **Log active status** check box and from the **Active field** drop-down list displayed, select the column used to hold the active status value for the SCD Type 2 method, which helps identify the active records, `active_status` in this example.

14. Select the **Log versions** check box and from the **Version field** drop-down list, select the column used to hold the version number of the records for the SCD Type 2 method, `version` in this example.

**Retrieving the data updates from the SCD dimension table**

**Procedure**

1. Double-click the first **tPostgreSQLInput** component to open its **Basic settings** view.
2. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

3. Click the `[...]` button next to **Edit schema** and in the pop-up dialog box, define the schema by adding nine columns: `sk` and `id` of Integer type as the primary key, `name` and `role` of String type, `salary` of Double type, `start_date` and `end_date` of Date type with the Date Pattern `yyyy-MM-dd`, and `active_status` and `version` of Integer type. When done, click **OK** to save the changes and close the dialog box.

The schema of the first `tPostgreSQLInput` component is the same as the schema of the `tPostgreSQLSCDELT1` component, you can just copy and paste it.

4. In the **Query** field, enter the SQL command used to retrieve data from the SCD dimension table, `select * from employee_scd` in this example.

5. In the **Table Name** field, enter the name of the SCD dimension table where you will retrieve the data updates, `employee_scd` in this example.

6. Double-click the first `tLogRow` component and in the **Mode** area on its **Basic settings** view, select **Table** to display the retrieved data in a table.

**Updating data in the Postgresql table**

**Procedure**

1. Double-click the second `tFixedFlowInput` component to open its **Basic settings** view.

2. Click the `[...]` button next to **Edit schema** and in the pop-up dialog box, define the schema by adding four columns: `id` of Integer type as the primary key, `name` and `role` of String type, and `salary` of Double type.

   This schema is the same as the schema of the first `tFixedFlowInput` component, you can just copy and paste it.

3. Click **OK** to save the schema changes. In the pop-up dialog box, click **Yes** to propagate the schema to the next component.

4. Select **Use Inline Content** in the **Mode** area. Then in the **Content** field displayed, enter the following employee data to update the existing data.

   1;Mark Smith;tester;15000.00
   2;Thomas Johnson;tester;18000.00
   3;Teddy Brown;writer;17000.00
   4;John Clinton;developer;19000.00

5. Double-click the second `tPostgreSQLOutput` component to open its **Basic settings** view.

6. Select the **Use an existing connection** check box and from the **Component List** drop-down list displayed, select the connection component to reuse the connection created by it, `tPostgreSQLConnection_1` in this example.

7. In the **Table** field, enter the name of the table, in which the data will be updated, `employee` in this example.

8. Select **Default** from the **Action on table** drop-down list.

9. Select **Insert or update** from the **Action on data** drop-down list.

**Tracking data update changes and writing the changes into the SCD dimension table**
Procedure
1. Double-click the second tPostgreSQLSCDELT component to open its Basic settings view.
2. Repeat 2 on page 2953 through 14 on page 2954 in the procedure Tracking inserted data changes and writing the changes into a SCD dimension table on page 2952 to configure the second tPostgreSQLSCDELT component.

Retrieve the data update changes from the SCD dimension table

Procedure
1. Double-click the second tPostgreSQLInput component to open its Basic settings view.
2. Repeat 2 on page 2955 through 5 on page 2955 in the procedure Retrieving the data updates from the SCD dimension table on page 2954 to configure the second tPostgreSQLInput component.
3. Double-click the second tLogRow component and in the Mode area on its Basic settings view, select Table to display the retrieved data in a table.

Executing the Job to track data changes in a PostgreSQL table using tPostgreSQLSCDELT

Procedure
1. Press Ctrl + S to save the Job.
2. Press F6 to execute the Job.

As shown above, the old role developer for Thomas Johnson is overwritten directly by the new role tester because SCD Type 1 is performed on the role column, and a new record with the surrogate key value set to 26 is created for Teddy Brown’s salary update from 13000.00 to 17000.00 because SCD Type 2 is performed on the salary column.
Related Scenario

For related topics, see tMysqlSCD on page 2508 and Tracking data changes in a Snowflake table using the tJDBCSCDELT component on page 1879.
tPostjob
Triggers a task required after the execution of a Job
tPostjob starts the execution of a postjob.

tPostjob Standard properties
These properties are used to configure tPostjob running in the Standard Job framework.
The Standard tPostjob component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. 
For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tPostjob is a start component and can only be used with an iterate connection to the next component. |

Connections

| Connections | Outgoing links (from this component to another): 
Trigger: On Component Ok. 
Incoming links (from one component to this one): 
Trigger: Synchronize; Parallelize. 
For further information regarding connections, see Talend Studio User Guide. |

For more information about the tPostjob component, see Talend Studio User Guide.

| Usage rule | tPrejob is a start component and can only be used with an iterate connection to the next component. |

Connections

| Connections | Outgoing links (from this component to another): Trigger: On Component Ok. Incoming links (from one component to this one): Trigger: Synchronize; Parallelize. For further information regarding connections, see Talend Studio User Guide. |

For more information about the tPrejob component, see Talend Studio User Guide.

Handling files before and after the execution of a data Job

In this scenario, a pre-job and a post-job are added to the Job describes in Finding duplicate files between two folders on page 1104 to handle files before and after the execution of the main data Job.
As described in the above-mentioned scenario, when the main data Job is started, it creates a temporary text file to store the fetched filenames. If the specified temporary file already exists, it will be overwritten.

To prevent possible loss of data, the pre-job saves a backup copy of the specified file by renaming it, if it exists, before the main Job is executed.

After the execution of the main data Job, the post-job deletes the temporary file created by the data Job and restores the backup file, if any.

**Adding and linking components**

**Procedure**

1. With the main Job open on the design workspace, add a tPrejob, a tPostjob, a tFileDelete, and two tFileCopy components to the Job.
2. Link the tPrejob component to the first tFileCopy component using a Trigger > On Component Ok connection to build the pre-job.
3. Link the tPostjob component the tFileDelete component using a Trigger > On Component Ok connection, and link the tFileDelete component to the other tFileCopy component to build the post-job.
4. Label the relevant components to better identify their roles.

**Configuring the components**

**Configuring the pre-job**

**About this task**

In the pre-job, the tPrejob component does not have any parameter or property to configure; it just triggers the tFileCopy component before the execution of the main data Job to rename the specified file, so all the required configurations are made in the tFileCopy component.

**Procedure**

1. Double-click the tFileCopy component to show its Basic settings view.
1. Fill the **File Name** field with the path and filename of the temporary text file to be renamed, *D:/temp/tempdata.csv* in this example.

2. In the **Destination directory** field, specify or browse to destination directory. In this example, we will save the backup copy in the same directory, *D:/temp/*.

3. Select the **Rename** check box, and specify the new filename in the **Destination filename** field, *backup-tempdata.csv*. Leave the other parameters as they are.

### Configuring the post-job

#### About this task

In the post-job, the **tPostjob** component does not have any parameter or property to configure; it just triggers the **tFileDelete** component after the execution of the main data Job to delete the temporary file used to store the fetched filenames, which then triggers the **tFileCopy** component to name the backup file back to its original name.

#### Procedure

1. In the **Basic settings** view of the **tFileDelete** component, fill the **File Name** field with the path and filename of the temporary file to be deleted, *D:/temp/tempdata.csv* in this example, and leave the other parameters as they are.

2. Double-click the **tFileCopy** component to open its **Basic settings** view.
3. Fill the **File Name** field with the path and filename of the backup file, `D:/temp/backup-tempdata.csv` in this example.

4. In the **Destination directory** field, specify or browse to destination directory, `D:/temp/` in this example.

5. Select the **Rename** check box, and specify the original name of the temporary file in the **Destination filename** field, `tempdata.csv`.

6. Select the **Remove source file** check box to remove the backup file after the renaming action. Leave the other parameters as they are.

**Expected execution result**

If the specified temporary file exists, its data will be saved in a backup copy before the main data Job is executed and restored thereafter.

If the temporary file does not exist, the two **tFileCopy** components will generate an error, but this does not prevent the main data Job from being executed.

For the execution result of the main data Job, see Finding duplicate files between two folders on page 1104.

**Related scenario**

For another scenario that uses the **tPrejob** component, see Creating a bar chart from the input data on page 350.
tPubSubOutput

Receives messages serialized into byte arrays by its preceding component and issues these messages into a given PubSub service.
tRedshiftBulkExec

Loads data into Amazon Redshift from Amazon S3, Amazon EMR cluster, Amazon DynamoDB, or remote hosts.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

tRedshiftBulkExec loads data into an Amazon Redshift table from an Amazon DynamoDB table or from data files located in an Amazon S3 bucket, an Amazon EMR cluster, or a remote host that is accessed using an SSH connection.

tRedshiftBulkExec Standard properties

These properties are used to configure tRedshiftBulkExec running in the Standard Job framework.

The Standard tRedshiftBulkExec component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Either Built-In or Repository.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Type in the name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

### Additional JDBC Parameters

Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL.

### Table Name

Specify the name of the table to be written. Note that only one table can be written at a time.

### Action on table

On the table defined, you can perform one of the following operations:

- **None**: No operation is carried out.
- **Drop and create table**: The table is removed and created again.
- **Create table**: The table does not exist and gets created.
- **Create table if not exists**: The table is created if it does not exist.
- **Drop table if exists and create**: The table is removed if it already exists and created again.
- **Clear table**: The table content is deleted. You have the possibility to rollback the operation.

### Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Data source type

Select the location of the source data to be loaded.

- **S3**: load data from a file in an Amazon S3 bucket.
- **EMR**: load data from an Amazon EMR cluster.
- **DynamoDB**: load data from an existing DynamoDB table.
- **Remote host**: load data from one or more remote hosts, such as Amazon Elastic Compute Cloud (Amazon EC2) instances or other computers.
Use an existing S3 connection

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

This option is available when **S3** is selected from the **Data source type** drop-down list.

Access Key/S3 Access Key

Specify the Access Key ID that uniquely identifies an AWS account. For how to get your Access Key and Access Secret Key, visit **Getting Your AWS Access Keys**.

**Note:**
- This option is not available if **Use an existing S3 connection** is selected.
- This option appears as **S3 Access Key** if you select **Remote host** from the **Data source type** drop-down list.

Secret Key/S3 Secret Key

Specify the Secret Access Key, constituting the security credentials in combination with the Access Key.

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**Note:**
- This option is not available if **Use an existing S3 connection** is selected.
- This option appears as **S3 Secret Key** if you select **Remote host** from the **Data source type** drop-down list.

Assume Role

Select this check box and specify the values for the following parameters used to create a new assumed role session.

- **IAM Role ARNs chains**: a series of chained roles, which may belong to other accounts, that your cluster can assume to access resources.
  
  You can chain a maximum of 10 roles.

- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.

This option is not available if **Use an existing S3 connection** is selected.

For more information on IAM Role ARNs chains, see **Authorizing Redshift service**.

Bucket/S3 bucket

Specify the name of the Amazon S3 bucket in which the file is located.

This field is available only when **S3** or **Remote host** is selected from the **Data source type** drop-down list.
Note: This field appears as **Bucket** if you select S3 from the **Data source type** drop-down list; it appears as **S3 bucket** if you select Remote host from the drop-down list.

The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see **S3ServiceException Errors**.

| **Key** | Specify the path to the file that contains the data to be loaded. This field is available only when **S3** is selected from the **Data source type** drop-down list. |
| **Cluster id** | Specify the ID of the cluster that stores the data to be loaded. This field is available only when **EMR** is selected from the **Data source type** drop-down list. |
| **HDFS path** | Specify the HDFS file path that references the data file. This field is available only when **EMR** is selected from the **Data source type** drop-down list. |
| **Table** | Specify the name of the DynamoDB table that contains the data to be loaded. This field is available only when **DynamoDB** is selected from the **Data source type** drop-down list. |
| **Read ratio** | Specify the percentage of the DynamoDB table’s provisioned throughput to use for the data load. This field is available only when **DynamoDB** is selected from the **Data source type** drop-down list. |
| **SSH manifest file** | Specify the object key for the SSH manifest file that provides the information used to open SSH connections and execute remote commands. This field is available only when **Remote host** is selected from the **Data source type** drop-down list. |

**Advanced settings**

| **File type** | Select the type of the file that contains the data to be loaded.  
- **Delimited file or CSV**: a delimited/CSV file.  
- **JSON**: a JSON file.  
- **AVRO**: an Avro file.  
- **Fixed width**: a fixed-width file.  
This list is available when **S3**, **EMR**, or **Remote host** is selected from the **Data source type** drop-down list. |
| **Fields terminated by** | Enter the character used to separate fields. This field is available only when **Delimited file or CSV** is selected from the **File type** list. |
| Enclosed by | Select the character in which the fields are enclosed.  
This list is available only when Delimited file or CSV is selected from the File type list. |
|------------|------------------------------------------------------------------|
| JSON mapping | Specify how to map the data elements in the source file to the columns in the target table on Amazon Redshift. The valid values are:  
- **auto**: Map the data by matching object keys or names in the source name/value pairs for a JSON file or field names in the Avro schema for an Avro file to the names of columns in the target table. The argument is case-sensitive and must be enclosed in double quotation marks.  
- **s3://jsonpaths_file**: Map the data using the named JSONPaths file. The parameter must be an Amazon S3 object key that is enclosed in double quotation marks and explicitly references a single file, for example, s3://mybucket/jsonpaths.txt. For more information, see Data Format Parameters.  
This field is available only when JSON or AVRO is selected from the File type list. |
| Fixed width mapping | Enter a string that specifies a user-defined column label and column width between double quotation marks. The format of the string is:  
ColumnLabel1:ColumnWidth1,ColumnLabel2:ColumnWidth2,...  
Note that the column label in the string has no relation to the table column name and it can be either a text string or an integer. The order of the label/width pairs must match the order of the table columns exactly.  
This field is available only when Fixed width is selected from the File type list. |
| Compressed by | Select this check box and from the list displayed select the compression type of the source file.  
This check box is available when S3, EMR, or Remote host is selected from the Data source type drop-down list. |
| Decrypt | Select this check box if the file is encrypted using Amazon S3 client-side encryption. In the Encryption key field displayed, specify the encryption key used to encrypt the file. Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Loading Encrypted Data Files from Amazon S3.  
This check box is available when S3 is selected from the Data source type drop-down list and Use an existing S3 connection is not selected in the Basic settings view. |
| Encoding | Select the encoding type of the data to be loaded from the list.  
This list is available when S3, EMR, or Remote host is selected from the Data source type drop-down list. |
| Date format | Select one of the following items from the list to specify the date format in the source data:  
- **NONE**: No date format is specified. |
- **PATTERN**: Select this item and specify the date format in the field displayed. The default date format is YYYY-MM-DD.
- **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the date format.

### Time format
Select one of the following items from the list to specify the time format in the source data:

- **NONE**: No time format is specified.
- **PATTERN**: Select this item and specify the time format in the field displayed. The default time format is YYYY-MM-DD HH:MI:SS.
- **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the time format.
- **EPOCHSECS**: Select this item if the source data is represented as epoch time, the number of seconds since Jan 1, 1970 00:00:00 UTC.
- **EPOCHMILLISECS**: Select this item if the source data is represented as epoch time, the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

### Settings
Click the `[+]` button below the table to specify more parameters for loading the data.

- **Parameter**: Click the cell and select a parameter from the drop-down list.
- **Value**: Set the value for the corresponding parameter. Note that you cannot set the value for a parameter (such as **IGNOREBLANKLINES**) that does not need a value.

For more information about the parameters, see [http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html](http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html).

### JDBC url
Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.

- **Standard**: Use the standard way to access the Redshift database.
- **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Before selecting this option, ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This option is available only when **Use an existing connection** check box is not selected from the **Basic settings**.

### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Note:
This component does not support the Row > Reject link.

Usage

Usage rule
The tRedshiftBulkExec component supports loading data to Amazon Redshift from a delimited/CSV, JSON, or fixed-width file on Amazon S3, but the tRedshiftOutputBulk component now only supports generating and uploading a delimited/CSV file to Amazon S3. When you need to load data from a JSON or fixed-width file, you can use the tFileOutputJSON or tFileOutputPositional component together with the tS3Put component instead of using the tRedshiftOutputBulk component to generate and upload the file to Amazon S3.

Dynamic settings
Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Loading/unloading data to/from Amazon S3

This scenario describes a Job that generates a delimited file and uploads the file to S3, loads data from the file on S3 to Redshift and displays the data on the console, then unloads the data from Redshift to files on S3 per slice of the Redshift cluster, and finally lists and gets the unloaded files on S3.
Prerequisites:
The following context variables have been created and saved in the Repository tree view. For more information about context variables, see Talend Studio User Guide.

- **redshift_host**: the connection endpoint URL of the Redshift cluster.
- **redshift_port**: the listening port number of the database server.
- **redshift_database**: the name of the database.
- **redshift_username**: the username for the database authentication.
- **redshift_password**: the password for the database authentication.
- **redshift_schema**: the name of the schema.
- **s3_accesskey**: the access key for accessing Amazon S3.
- **s3_secretkey**: the secret key for accessing Amazon S3.
- **s3_bucket**: the name of the Amazon S3 bucket.
Adding and linking components

Procedure
1. Create a new Job and apply all context variables listed above to the new Job.
2. Add the following components by typing their names in the design workspace or dropping them from the Palette: a `tRowGenerator` component, a `tRedshiftOutputBulk` component, a `tRedshiftBulkExec` component, a `tRedshiftInput` component, a `tLogRow` component, a `tRedshiftUnload` component, a `tS3List` component, and a `tS3Get` component.
3. Link `tRowGenerator` to `tRedshiftOutputBulk` using a Row > Main connection.
4. Do the same to link `tRedshiftInput` to `tLogRow`.
5. Link `tS3List` to `tS3Get` using a Row > Iterate connection.
6. Link `tRowGenerator` to `tRedshiftBulkExec` using a Trigger > On Subjob Ok connection.
7. Do the same to link `tRedshiftBulkExec` to `tRedshiftInput`, link `tRedshiftInput` to `tRedshiftUnload`, link `tRedshiftUnload` to `tS3List`.

Configuring the components

Preparing a file and uploading the file to S3

Procedure
1. Double-click `tRowGenerator` to open its RowGenerator Editor.
2. Click the [+] button to add two columns: ID of Integer type and Name of String type.

3. Click the cell in the Functions column and select a function from the list for each column. In this example, select Numeric.sequence to generate sequence numbers for the ID column and select TalendDataGenerator.getFirstName to generate random first names for the Name column.

4. In the Number of Rows for RowGenerator field, enter the number of data rows to generate. In this example, it is 20.

5. Click OK to close the schema editor and accept the propagation prompted by the pop-up dialog box.

6. Double-click tRedshiftOutputBulk to open its Basic settings view on the Component tab.

7. In the Data file path at local field, specify the local path for the file to be generated. In this example, it is E:/Redshift/redshift_bulk.txt.

8. In the Access Key field, press Ctrl + Space and from the list select context.s3_accesskey to fill in this field.
   Do the same to fill the Secret Key field with context.s3_accesskey and the Bucket field with context.s3_bucket.

9. In the Key field, enter a new name for the file to be generated after being uploaded on Amazon S3. In this example, it is person_load.
Loading data from the file on S3 to Redshift

Procedure

1. Double-click tRedshiftBulkExec to open its Basic settings view on the Component tab.

![tRedshiftBulkExec_1.png](image)

2. In the Host field, press Ctrl + Space and from the list select context.redshift_host to fill in this field. Do the same to fill:
   - the Port field with context.redshift_port,
   - the Database field with context.redshift_database,
   - the Schema field with context.redshift_schema,
   - the Username field with context.redshift_username,
   - the Password field with context.redshift_password,
   - the Access Key field with context.s3_accesskey,
   - the Secret Key field with context.s3_secretkey, and
   - the Bucket field with context.s3_bucket.

3. In the Table Name field, enter the name of the table to be written. In this example, it is person.

4. From the Action on table list, select Drop table if exists and create.

5. In the Key field, enter the name of the file on Amazon S3 to be loaded. In this example, it is person_load.

6. Click the [...] button next to Edit schema and in the pop-up window define the schema by adding two columns: ID of Integer type and Name of String type.
Retrieving data from the table on Redshift

Procedure

1. Double-click `tRedshiftInput` to open its **Basic settings** view on the **Component** tab.

2. Fill the **Host**, **Port**, **Database**, **Schema**, **Username**, and **Password** fields with their corresponding context variables.

3. In the **Table Name** field, enter the name of the table to be read. In this example, it is `person`.

4. Click the [...] button next to **Edit schema** and in the pop-up window define the schema by adding two columns: **ID** of Integer type and **Name** of String type.

5. In the **Query** field, enter the following SQL statement based on which the data are retrieved.

   ```sql
   "SELECT * FROM" + context.redshift_schema + "person ORDER BY \"ID\"
   ```

6. Double-click `tLogRow` to open its **Basic settings** view on the **Component** tab.
7. In the **Mode** area, select **Table (print values in cells of a table)** for a better display of the result.

### Unloading data from Redshift to file(s) on S3

#### Procedure

1. Double-click **tRedshiftUnload** to open its **Basic settings** view on the **Component** tab.

2. Fill the **Host**, **Port**, **Database**, **Schema**, **Username**, and **Password** fields with their corresponding context variables. Fill the **Access Key**, **Secret Key**, and **Bucket** fields also with their corresponding context variables.

3. In the **Table Name** field, enter the name of the table from which the data will be read. In this example, it is **person**.

4. Click the [...] button next to **Edit schema** and in the pop-up window define the schema by adding two columns: **ID** of Integer type and **Name** of String type.

5. In the **Query** field, enter the following SQL statement based on which the result will be unloaded.

   ```sql
   "SELECT * FROM person"
   ```

6. In the **Key prefix** field, enter the name prefix for the unload files. In this example, it is **person_unload_**.
Retrieving files unloaded to Amazon S3

Procedure

1. Double-click tS3List to open its **Basic settings** view on the **Component** tab.

![tS3List_1](image)

   - **Connection**
     - Use an existing connection
   - **Access Key** context.s3_accesskey
   - **Secret Key** context.s3_secretkey
   - Inherit credentials from AWS role
   - Assume Role
   - **Region** US Standard
   - List all buckets objects
   - **Bucket**
     - Bucket name: context.s3_bucket
     - Key prefix: person_unload_
   - Die on error

2. Fill the **Access Key** and **Secret Key** fields with their corresponding context variables.
3. From the **Region** list, select the AWS region where the unload files are created. In this example, it is **US Standard**.
4. Clear the **List all buckets objects** check box, and click the [+\] button under the table displayed to add one row.
   - Fill in the **Bucket name** column with the name of the bucket in which the unload files are created. In this example, it is the context variable context.s3_bucket.
   - Fill in the **Key prefix** column with the name prefix for the unload files. In this example, it is person_unload_.
5. Double-click tS3Get to open its **Basic settings** view on the **Component** tab.

![tS3Get_1](image)

   - **Connection**
     - Use an existing connection
   - **Access Key** context.s3_accesskey
   - **Secret Key** context.s3_secretkey
   - Inherit credentials from AWS role
   - Assume Role
   - **Region** US Standard
   - **Encrypt**
   - **Bucket** context.s3_bucket
   - **Key** (String)globalMap.get("TS3List_1_CURRENT_KEY")
   - **File** E:/Redshift/ + (String)globalMap.get("TS3List_1_CURRENT_KEY")
   - Die on error

6. Fill the **Access Key** field and **Secret Key** field with their corresponding context variables.
7. From the **Region** list, select the AWS region where the unload files are created. In this example, it is **US Standard**.
8. In the **Bucket** field, enter the name of the bucket in which the unload files are created. In this example, it is the context variable `context.s3_bucket`.

   In the **Key** field, enter the name of the unload files by pressing **Ctrl + Space** and from the list selecting the global variable `((String)globalMap.get("tS3List_1_CURRENT_KEY"))`.

9. In the **File** field, enter the local path where the unload files are saved. In this example, it is `E:/Redshift/ + ((String)globalMap.get("tS3List_1_CURRENT_KEY"))`.

### Saving and executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

```java
[statistics] connecting to socket on port 3726
[statistics] connected

[statistics] disconnected

---

![Image of AWS S3 bucket](image-url)
As shown above, the generated data is written into the local file `redshift_bulk.txt`, the file is uploaded on S3 with the new name `person_load`, and then the data is loaded from the file on S3 to the table `person` in Redshift and displayed on the console. After that, the data is unloaded from the table `person` in Redshift to two files `person_unload_0000_part_00` and `person_unload_0001_part_00` on S3 per slice of the Redshift cluster, and finally the unloaded files on S3 are listed and retrieved in the local folder.
**tRedshiftClose**

Closes the transaction committed in the connected DB.

This component is used together with tRedShiftConnection and tRedshiftCommit to ensure the integrity of the transaction performed into the database.

**tRedshiftClose Standard properties**

These properties are used to configure tRedshiftClose running in the Standard Job framework.

The Standard tRedshiftClose component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

---

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

---

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current Job.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is to be used along with Amazon Redshift components, especially with tRedshiftConnection and tRedshiftCommit. |

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic
**Related scenario**

For a related scenario, see *Handling data with Redshift* on page 2991.
tRedshiftCommit

Provides gain in performance.
Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch.
tRedshiftCommit validates the data processed through the Job into the connected database.

**tRedshiftCommit Standard properties**

These properties are used to configure tRedshiftCommit running in the Standard Job framework.
The Standard tRedshiftCommit component belongs to the Cloud and the Databases families.
The component in this framework is available in all Talend products.

*Note:* This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

*Warning:* If you want to use a Row > Main connection to link tRedshiftCommit to your Job, your data will be committed row by row. In this case, do not select the Close Connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the tRedshiftConnection and tRedshiftRollback components. |
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database |
connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

For a similar scenario, see Inserting data in mother/daughter tables on page 2426.
**tRedshiftConnection**

Opens a connection to the specified database that can then be reused in the subsequent subjob or subjobs.  

tRedshiftConnection opens a connection to the database for a current transaction.

**tRedshiftConnection Standard properties**

These properties are used to configure tRedshiftConnection running in the Standard Job framework.  
The Standard tRedshiftConnection component belongs to the Cloud and the Databases families.  
The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Host</td>
<td>Host name or IP address of DB server.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of DB server.</td>
</tr>
</tbody>
</table>
| Database | Name of the database.  
The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors. |
| Schema | Name of the schema. |
| Username and Password | DB user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| Additional JDBC Parameters | Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, ssl=true & ssifactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL. |
### Use or register a shared DB Connection

Select this check box to share your database connection or fetch a database connection shared by a parent or child Job, and in the **Shared DB Connection Name** field displayed, enter the name for the shared database connection. This allows you to share one single database connection (except the database schema setting) among several database connection components from different Job levels that can be either parent or child.

This option is incompatible with the **Use dynamic job** and **Use an independent process to run subjob** options of the tRunJob component. Using a shared connection together with a tRunJob component with either of these two options enabled will cause your Job to fail.

### Advanced settings

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Log file</strong></td>
<td>Specify the path to the log file to be generated during the data retrieval process. Note that if the logging information needs to be saved and this component reuses the connection created by a tRedshiftConnection component, you must specify the property <code>loglevel=1/2/3</code> in the Additional JDBC Parameters field of the tRedshiftConnection component. There is no limitation on the size of the log file. If the specified log file already exists, it will be overwritten.</td>
</tr>
<tr>
<td><strong>Logging level</strong></td>
<td>Select a logging level from the drop-down list to specify which kind of events will be logged in the log file.</td>
</tr>
<tr>
<td><strong>Auto Commit</strong></td>
<td>Select this check box to commit any changes to the database automatically upon the transaction. With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component. Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your transactions in a Job, it is recommended to use the commit component.</td>
</tr>
<tr>
<td><strong>JDBC url</strong></td>
<td>Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Standard</strong>: Use the standard way to access the Redshift database.</td>
</tr>
<tr>
<td></td>
<td>• <strong>SSO</strong>: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Before selecting this option, ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.</td>
</tr>
</tbody>
</table>
This option is available only when **Use an existing connection** check box is not selected from the **Basic settings**.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Usage**

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the **tRedshiftCommit** and **tRedshiftRollback** components. |

| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenario**

For a related scenario, see **Handling data with Redshift** on page 2991.
tRedshiftInput

Reads data from a database and extracts fields based on a query so that you may apply changes to the extracted data.

tRedshiftInput executes a DB query with a strictly defined order which must correspond to the schema definition. Then it passes on the field list to the next component through a Main row link.

**tRedshiftInput Standard properties**

These properties are used to configure tRedshiftInput running in the Standard Job framework.

The Standard tRedshiftInput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>![Database Icon]</td>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component Basic settings view. For more information about setting up and storing database connection parameters, see Talend Studio User Guide.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

<table>
<thead>
<tr>
<th>Host</th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database user authentication data.</td>
</tr>
<tr>
<td></td>
<td>To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td>Schema and Edit Schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td></td>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td></td>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate
the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th><strong>Table Name</strong></th>
<th>Name of the table from which the data will be read.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Query Type and Query</strong></td>
<td>Enter your database query paying particularly attention to sequence the fields properly in order to match the schema definition.</td>

</tbody>
</table>

### Advanced settings

| **Log file** | Specify the path to the log file to be generated during the data retrieval process. Note that if the logging information needs to be saved and this component reuses the connection created by a tRedshiftConnection component, you must specify the property loglevel=1/2/3 in the Additional JDBC Parameters field of the tRedshiftConnection component. There is no limitation on the size of the log file. If the specified log file already exists, it will be overwritten. |
| **Logging level** | Select a logging level from the drop-down list to specify which kind of events will be logged in the log file. |
| **Use cursor** | Select this check box to help to decide the row set to work with at a time and thus optimize performance. |
| **Trim all the String/Char columns** | Select this check box to remove leading and trailing whitespace from all the String/Char columns. |
| **Trim column** | Remove leading and trailing whitespace from defined columns. |
| **JDBC url** | Select a way to access to an Amazon Redshift database from the JDBC url drop-down list. |
| | - **Standard**: Use the standard way to access the Redshift database. |
| | - **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Before selecting this option, ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details. This option is available only when Use an existing connection check box is not selected from the Basic settings. |
| **tStatCatcher Statistics** | Select this check box to collect log data at the component level. |
Global Variables

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>QUERY</td>
<td>the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component covers all possible SQL queries for Amazon Redshift databases.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).
Handling data with Redshift

This scenario describes a Job that writes the personal information into Redshift, then retrieves the information in Redshift and displays it on the console.

- **tRedshiftConnection**: opens a connection to Redshift.
- **tFixedFlowInput**: defines the personal information data structure, and sends the data to the next component.
- **tRedshiftOutput**: writes the data it receives from the preceding component into Redshift.
- **tRedshiftInput**: reads the data from Redshift.
- **tLogRow**: displays the data it receives from the preceding component on the console.
- **tRedshiftClose**: closes the connection to Redshift.

**Dropping and linking the components**

**Procedure**

1. Drop the six components listed previously from the Palette onto the design workspace.
2. Connect tFixedFlowInput to tRedshiftOutput using a Row > Main connection.
3. Connect tRedshiftInput to tLogRow also using a Row > Main connection.
4. Connect tRedshiftConnection to tFixedFlowInput using a Trigger > OnSubjobOk connection.
5. Connect tFixedFlowInput to tRedshiftInput and tRedshiftInput to tRedshiftClose also using a Trigger > OnSubjobOk connection.
Configuring the components

Opening a connection to Redshift

Procedure

1. Double-click tRedshiftConnection to open its Basic settings view.

   ![tRedshiftConnection view]

   2. Select Built-In from the Property Type drop-down list.

   In the Host, Port, Database, Schema, Username, and Password fields, enter the information required for the connection to Redshift.

   3. In Advanced settings view, select Auto Commit check box to commit any changes to Redshift upon each transaction.

Defining the input data

Procedure

1. Double-click tFixedFlowInput to open its Basic settings view.

   ![tFixedFlowInput view]

   2. Click the [...] button next to Edit schema to open the schema editor.
3. In the schema editor, click the [+ ] button to add three columns: id of the integer type, name of the string type, and age of the integer type.

4. Click OK to validate the changes and accept the propagation prompted by the pop-up [Propagate] dialog box.

5. In the Mode area, select Use Inline Content (delimited file) and enter the following personal information in the Content field.

```
1;Arthur;16
2;Ford;18
3;Jackson;17
```

Writing the data into Redshift

Procedure

1. Double-click tRedshiftOutput to open its Basic settings view.

2. Select the Use an existing connection check box, and then select the connection you have already configured for tRedshiftConnection from the Component List drop-down list.

3. In the Table field, enter or browse to the table into which you want to write the data, redshiftexample in this scenario.

4. Select Drop table if exists and create from the Action on table drop-down list, and select Insert from the Action on data drop-down list.

5. Click Sync columns to retrieve the schema from the preceding component tFixedFlowInput.
Retrieving the data from Redshift

Procedure

1. Double-click tRedshiftInput to open its Basic settings view.

2. Select the Use an existing connection check box, and then select the connection you have already configured for tRedshiftConnection from the Component List drop-down list.

3. Click the [...] button next to Edit schema to open the schema editor.

4. In the schema editor, click the [+] button to add three columns: id of the integer type, name of the string type, and age of the integer type. The data structure is same as the structure you have defined for tFixedFlowInput.

5. Click OK to validate the changes and accept the propagation prompted by the pop-up [Propagate] dialog box.

6. In the Table Name field, enter or browse to the table into which you write the data, redshiftexample in this scenario.

7. Click the Guess Query button to generate the query. The Query field will be filled with the automatically generated query.

Displaying the defined information

Procedure

1. Double-click tLogRow to open its Basic settings view.

2. In the Mode area, select Table (print values in cells of a table) for a better view of the results.
Closing the connection to Redshift

Procedure

1. Double-click tRedshiftClose to open its Basic settings view.

2. From Component List, select the connection you have already configured for tRedshiftConnection.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save the Job.
2. Press F6 to execute the Job.

```
Starting job DOCT3191_tRedshift_501 at 17:18 19/03/2014
[statistics] connecting to socket on port 3000
[statistics] connected

<table>
<thead>
<tr>
<th>LogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>id</td>
</tr>
<tr>
<td>-----</td>
</tr>
<tr>
<td>1</td>
</tr>
<tr>
<td>2</td>
</tr>
<tr>
<td>3</td>
</tr>
</tbody>
</table>

[statistics] disconnected
Job DOCT3191_tRedshift_501 ended at 17:18 19/03/2014. [exit code=0]
```

The personal information is written to the specified target Redshift database, and then the data is retrieved from the database and displayed on the console.
tRedshiftOutput

Writes, updates, modifies or deletes the data in a database.

tRedshiftOutput executes the action defined on the table and/or on the data of a table, according to the input flow from the previous component.

**tRedshiftOutput Standard properties**

These properties are used to configure tRedshiftOutput running in the Standard Job framework.

The Standard tRedshiftOutput component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either <strong>Built-in</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository: Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
<td></td>
</tr>
<tr>
<td>Click this icon to open a database connection wizard and store the database connection parameters you set in the component <strong>Basic settings</strong> view.</td>
<td></td>
</tr>
<tr>
<td>For more information about setting up and storing database connection parameters, see <strong>Talend Studio User Guide</strong>.</td>
<td></td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>
**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see *Talend Studio User Guide*.

<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the database server.</td>
</tr>
</tbody>
</table>
| **Database** | Database name.  
The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see [S3ServiceException Errors](#). |
| **Schema** | Exact name of the schema. |
| **Username and Password** | Database user authentication data.  
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **Additional JDBC Parameters** | Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand & and each property is a key-value pair. For example, `ssl=true & sslfactory=com.amazon.redshift.ssl.NonValidatingFactory`, which means the connection will be created using SSL. |
| **Table** | Name of the table to which the data will be written. Note that only one table can be written at a time. |
| **Action on table** | On the table defined, you can perform one of the following operations:  
**None**: No operation is carried out.  
**Drop and create a table**: The table is removed and created again.  
**Create a table**: The table does not exist and gets created.  
**Create a table if not exists**: The table is created if it does not exist.  
**Drop a table if exists and create**: The table is removed if already exists and created again.  
**Clear a table**: The table content is deleted. |
### Action on data

On the data of the table defined, you can perform:

- **Insert**: Add new entries to the table. If duplicates are found, the operation will stop.
- **Update**: Make changes to existing entries.
- **Insert or update**: Insert a new record. If the record with the given reference already exists, an update would be made.
- **Update or insert**: Update the record with the given reference. If the record does not exist, a new record would be inserted.
- **Delete**: Remove entries corresponding to the input flow.

**Warning:**

*It is necessary to specify at least one column as a primary key on which the Update and Delete operations are based. You can do that by clicking Edit Schema and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, click the Advanced settings view where you can simultaneously define primary keys for the Update and Delete operations. To do that: Select the Use field options check box and then in the Key in update column, select the check boxes next to the column names you want to use as a base for the Update operation. Do the same in the Key in delete column for the Delete operation.*

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center ([https://help.talend.com](https://help.talend.com)).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon
### Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use alternate schema</strong></td>
<td>Select this option to use a schema other than the one specified by the component that establishes the database connection (that is, the component selected from the Component list drop-down list in Basic settings view). After selecting this option, provide the name of the desired schema in the Schema field. This option is available when Use an existing connection is selected in Basic settings view.</td>
</tr>
<tr>
<td><strong>Extend Insert</strong></td>
<td>Select this check box to carry out a bulk insert of a defined set of lines instead of inserting lines one by one. The gain in system performance is considerable. <strong>Number of rows per insert</strong>: enter the number of rows to be inserted per operation. Note that the higher the value specified, the lower performance levels shall be due to the increase in memory demands. Amazon Redshift requires the number of rows per insert to be less than 32767. For this reason, if the number you enter exceeds this maximum limit, the Studio automatically resets this number below this limit. <strong>Note</strong>: This option is not compatible with the Reject link. You should therefore clear the check box if you are using a Row &gt; Rejects link with this component.</td>
</tr>
<tr>
<td><strong>Use Batch</strong></td>
<td>Select this check box to activate the batch mode for data processing. <strong>Note</strong>: This check box is available only when you have selected the Update or the Delete option in the Action on data field.</td>
</tr>
<tr>
<td><strong>Batch Size</strong></td>
<td>Specify the number of records to be processed in each batch. This field appears only when the Use batch mode check box is selected.</td>
</tr>
<tr>
<td><strong>Commit every</strong></td>
<td>Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</td>
</tr>
<tr>
<td><strong>Additional Columns</strong></td>
<td>This option is not offered if you create (with or without drop) the DB table. This option allows you to call SQL.</td>
</tr>
</tbody>
</table>
functions to perform actions on columns, which are not insert, nor update or delete actions, or action that require particular preprocessing.

| Name: | Type in the name of the schema column to be altered or inserted as new column. |
| SQL expression: | Type in the SQL statement to be executed in order to alter or insert the relevant column data. |
| Position: | Select Before, Replace or After following the action to be performed on the reference column. |
| Reference column: | Type in a column of reference that the tDBOutput can use to place or replace the new or altered column. |

Use field options

Select this check box to customize a request, especially when there is double action on data.

JDBC url

Select a way to access to an Amazon Redshift database from the JDBC url drop-down list.

- **Standard**: Use the standard way to access the Redshift database.
- **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Before selecting this option, ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This option is available only when Use an existing connection check box is not selected from the Basic settings.

**Note:**
The Row > Reject link is not available if any of these three options is selected: Die on error, Extend Insert, and Use Batch. Also, to make sure your job runs properly, do not select any of these three options with the presence of the Row > Reject link.

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_UPDATED</strong></td>
<td>the number of rows updated. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**Usage**

| Usage rule | This component covers all possible SQL database queries. It allows you to carry out actions on a table or on the data of a table in an Amazon Redshift database. It enables you to create a reject flow, with a Row > Rejects link filtering the data in error. For a usage example, see Retrieving data in error with a Reject link on page 2474. |
| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
| Limitation | Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com). |

**Related scenarios**

For a related scenario, see Handling data with Redshift on page 2991.
tRedshiftOutputBulk

Prepares a delimited/CSV file that can be used by tRedshiftBulkExec to feed Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and then uploads the file to Amazon S3.

**tRedshiftOutputBulk Standard properties**

These properties are used to configure tRedshiftOutputBulk running in the Standard Job framework. The Standard tRedshiftOutputBulk component belongs to the Cloud and the Databases families. The component in this framework is available in all Talend products.

*Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.*

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Database</strong></th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
</table>
| **Data file path at local** | Specify the local path to the file to be generated.  
Note that the file is generated on the same machine where the Studio is installed or where the Job using this component is deployed. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| | **Built-In**: You create and store the schema locally for this component only. |
| | **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |
| | Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes. |
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Compress the data file</td>
<td>Select this check box and select a compression type from the list displayed to compress the data file. This check box disappears when the Append the local file check box is selected.</td>
</tr>
<tr>
<td>Encrypt</td>
<td>Select this check box to generate and upload the data file to Amazon S3 using client-side encryption. In the Encryption key field displayed, enter the encryption key used to encrypt the file. By default, this check box is cleared and the data file will be uploaded to Amazon S3 using server-side encryption. Note: This option is available when Use an existing S3 connection is not selected. For more information about the client-side and server-side encryption, see Protecting Data Using Encryption.</td>
</tr>
<tr>
<td>Access Key</td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys. Note: This option is available when both Use an existing S3 connection and Inherit credentials from AWS role are cleared.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. Note: This option is available when both Use an existing S3 connection and Inherit credentials from AWS role are cleared.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances. Note: This option is available when Use an existing S3 connection is not selected.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify</td>
</tr>
</tbody>
</table>
the values for the following parameters to create a new assumed role session.

Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator.

**Note:** This option is available when **Use an existing S3 connection** is not selected.

- **Role ARN:** the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like `arn:aws:iam::[aws_account_number]:role/[role_name]`.
- **Role session name:** enter the name you want to use to uniquely identify your assumed role session. This name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters: =,.@-.
- **Session duration (minutes):** the duration (in minutes) for which you want the assumed role session to be active. This duration cannot exceed the maximum duration which your AWS administrator has set.

For an example about an IAM role and its related policy types, see Create and Manage AWS IAM Roles from the AWS documentation.

### Region

Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see Regions and Endpoints.

**Note:** This option is available when **Use an existing S3 connection** is not selected.

### STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.

### Bucket

Type in the name of the Amazon S3 bucket, namely the top level folder, to which the file is uploaded.

The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.

### Key

Type in an object key to assign to the file uploaded to Amazon S3.

### Advanced settings

**Field Separator**

Enter the character used to separate fields.
<table>
<thead>
<tr>
<th>Text enclosure</th>
<th>Select the character in a pair of which the fields are enclosed.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete local file after putting it to s3</td>
<td>Select this check box to delete the local file after being uploaded to Amazon S3. By default, this check box is selected.</td>
</tr>
<tr>
<td>Create directory if not exists</td>
<td>Select this check box to create the directory specified in the <strong>Data file path at local</strong> field if it does not exist. By default, this check box is selected.</td>
</tr>
<tr>
<td>Encoding</td>
<td>Select an encoding type for the data in the file to be generated.</td>
</tr>
</tbody>
</table>
| Config client | Select this check box to configure client parameters for Amazon S3. Click the [+ ] button below the table displayed to add as many rows as needed, each row for a client parameter, and set the following attributes for each parameter:  
  • **Client Parameter**: Click the cell and select a parameter from the drop-down list.  
  • **Value**: Enter the value for the corresponding client parameter.  
  For information about S3 client parameters, go to **Client Configuration**. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables |  
|------------------|---------------------------------------------------------------|
| **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.  
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see **Talend Studio User Guide**. |

### Usage

| Usage rule | This component is more commonly used with the **tRedshiftBulkExec** component to feed Amazon Redshift with a delimited/CSV file. Used together they offer gains in performance while feeding Amazon Redshift. |
Related scenario

For a related scenario, see Loading/unloading data to/from Amazon S3 on page 2970.
**tRedshiftOutputBulkExec**

Executes the Insert action on the data provided.

As a dedicated component, it allows gains in performance during Insert operations to Amazon Redshift.

The tRedshiftOutputBulk and tRedshiftBulkExec components can be used together in a two step process to load data to Amazon Redshift from a delimited/CSV file on Amazon S3. In the first step, a delimited/CSV file is generated. In the second step, this file is used in the INSERT statement used to feed Amazon Redshift. These two steps are fused together in the tRedshiftOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded to Amazon Redshift.

This component receives data from the preceding component, generates a single delimited/CSV file and uploads the file to Amazon S3, finally it loads the data from Amazon S3 to Redshift.

**tRedshiftOutputBulkExec Standard properties**

These properties are used to configure tRedshiftOutputBulkExec running in the Standard Job framework.

The Standard tRedshiftOutputBulkExec component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Database</strong></td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td><strong>Property Type</strong></td>
<td>Either <strong>Built-In</strong> or <strong>Repository</strong>.</td>
</tr>
<tr>
<td><strong>Built-In</strong>:</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong>:</td>
<td>Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Host</strong></td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td><strong>Port</strong></td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Type in the name of the database.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Type in the name of the schema.</td>

<td>---</td>
<td>---</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click <strong>OK</strong> to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, <code>ssl=true &amp; ssifactory=com.amazon.redshift.ssl.NonValidatingFactory</code>, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Specify the name of the table to be written. Note that only one table can be written at a time.</td>
</tr>
</tbody>
</table>
| **Action on table** | On the table defined, you can perform one of the following operations:  
  • **None**: No operation is carried out.  
  • **Drop and create table**: The table is removed and created again.  
  • **Create table**: The table does not exist and gets created.  
  • **Create table if not exists**: The table is created if it does not exist.  
  • **Drop table if exists and create**: The table is removed if it already exists and created again.  
  • **Clear table**: The table content is deleted. You have the possibility to rollback the operation. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.  
  **Built-in**: You create and store the schema locally for this component only.  
  **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  • **View schema**: choose this option to view the schema only.  
  • **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  • **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to
propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

<table>
<thead>
<tr>
<th><strong>Data file path at local</strong></th>
<th>Specify the local path to the file to be generated. Note that the file is generated on the same machine where the Studio is installed or where the Job using this component is deployed.</th>

<tbody>
<tr>
<td>Fields terminated by</td>
<td>Enter the character used to separate fields.</td>
</tr>
<tr>
<td>Enclosed by</td>
<td>Select the character in a pair of which the fields are enclosed.</td>
</tr>
<tr>
<td>Compressed by</td>
<td>Select this check box and select a compression type from the list displayed to compress the data file. This field disappears when the Append the local file check box is selected.</td>
</tr>
</tbody>
</table>
| Encrypt             | Select this check box to generate and upload the data file to Amazon S3 using client-side encryption. In the Encryption key field displayed, specify the encryption key used to encrypt the file. Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see [Loading Encrypted Data Files from Amazon S3](#).

By default, this check box is cleared and the data file will be uploaded to Amazon S3 using server-side encryption.

For more information about the client-side and server-side encryption, see [Protecting Data Using Encryption](#).

**Note**: This field is available when **Use an existing S3 connection** is not selected.

<table>
<thead>
<tr>
<th>Encoding</th>
<th>Select an encoding type for the data in the file to be generated.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Delete local file after putting it to s3</td>
<td>Select this check box to delete the local file after being uploaded to Amazon S3. By default, this check box is selected.</td>
</tr>
</tbody>
</table>
| Date format         | Select one of the following items from the list to specify the date format in the source data:  
  - **NONE**: No date format is specified.  
  - **PATTERN**: Select this item and specify the date format in the field displayed. The default date format is YYYY-MM-DD.  
  - **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the date format. |
| Time format         | Select one of the following items from the list to specify the time format in the source data:  
  - **NONE**: No time format is specified. |
- **PATTERN**: Select this item and specify the time format in the field displayed. The default time format is YYYY-MM-DD HH:MI:SS.
- **AUTO**: Select this item if you want Amazon Redshift to recognize and convert automatically the time format.
- **EPOCHSECS**: Select this item if the source data is represented as epoch time, the number of seconds since Jan 1, 1970 00:00:00 UTC.
- **EPOCHMILLISECS**: Select this item if the source data is represented as epoch time, the number of milliseconds since Jan 1, 1970 00:00:00 UTC.

**Settings**

Click the [+] button below the table to specify more parameters for loading the data.

- **Parameter**: Click the cell and select a parameter from the drop-down list.
- **Value**: Set the value for the corresponding parameter. Note that you cannot set the value for a parameter (such as `IGNOREBLANKLINES`) that does not need a value.

For more information about the parameters, see [http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html](http://docs.aws.amazon.com/redshift/latest/dg/r_COPY.html).

**Config client**

Select this check box to configure client parameters for Amazon S3. Click the [+] button below the table displayed to add as many rows as needed, each row for a client parameter, and set the following attributes for each parameter:

- **Client Parameter**: Click the cell and select a parameter from the drop-down list.
- **Value**: Enter the value for the corresponding client parameter.

For information about S3 client parameters, go to [Client Configuration](#).

**JDBC url**

Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.

- **Standard**: Use the standard way to access the Redshift database.
- **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Before selecting this option, ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This option is available only when **Use an existing connection** check box is not selected from the **Basic settings**.

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

**Global Variables**

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is mainly used when no particular transformation is required on the data to be loaded to Amazon Redshift.</th>
</tr>
</thead>
</table>
| Dynamic settings | Click the [*] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

Related scenario

For a related scenario, see Loading/unloading data to/from Amazon S3 on page 2970.
tRedshiftRollback

Cancels the transaction commit in the Redshift database to avoid committing part of a transaction involuntarily.

tRedshiftRollback Standard properties

These properties are used to configure tRedshiftRollback running in the Standard Job framework.

The Standard tRedshiftRollback component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tRedshiftConnection component in the list if more than one connection are planned for the current job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

Advanced settings

| tStat Catcher Statistics | Select this check box to collect log data at the component level. |

Usage

| Usage rule | This component is more commonly used with other tRedshift* components, especially with the tRedshiftConnection and tRedshiftCommit components. |
| Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection.
Related scenario

For a similar scenario, see Rollback from inserting data in mother/daughter tables on page 2429.
tRedshiftRow

Acts on the actual DB structure or on the data (although without handling data), depending on the nature of the query and the database.

The SQLBuilder tool helps you write easily your SQL statements.

tRedshiftRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the job design although it does not provide output.

tRedshiftRow Standard properties

These properties are used to configure tRedshiftRow running in the Standard Job framework.

The Standard tRedshiftRow component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property type</td>
<td>Either Built-in or Repository.</td>
</tr>
<tr>
<td>Built-in</td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td>Repository</td>
<td>Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note: When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Hostname or IP address of the database server.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Port</strong></td>
<td>Listening port number of the database server.</td>
</tr>
<tr>
<td><strong>Database</strong></td>
<td>Name of the database. The bucket and the Redshift database to be used must be in the same region on Amazon. This could avoid the S3ServiceException errors known to Amazon. For further information about these errors, see S3ServiceException Errors.</td>
</tr>
<tr>
<td><strong>Schema</strong></td>
<td>Exact name of the schema.</td>
</tr>
<tr>
<td><strong>Username and Password</strong></td>
<td>Database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td><strong>Schema and Edit Schema</strong></td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In</strong>: You create and store the schema locally for this component only. <strong>Repository</strong>: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
<tr>
<td><strong>Table Name</strong></td>
<td>Name of the table from which the data will be read.</td>
</tr>
<tr>
<td><strong>Query type</strong></td>
<td>Either Built-in or Repository. Built-in: Fill in manually the query statement or build it graphically using SQLBuilder.</td>
</tr>
</tbody>
</table>
**Repository:** Select the relevant query stored in the Repository. The **Query** field gets accordingly filled in.

**Guess Query**
Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

**Query**
Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.

*Note:* All statements in this field will be executed in a single transaction. To have multiple statements executed in different transactions, put each of them in a separate tRedShiftRow component.

**Die on error**
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows. If needed, you can retrieve the rows on error through a Row > Rejects link.

## Advanced settings

### Propagate QUERY’s recordset
Select this check box to insert the result of the query into a COLUMN of the current flow. Select this column from the **use column** list.

*Note:*
This option allows the component to have a different schema from that of the preceding component. Moreover, the column that holds the QUERY’s recordset should be set to the type of **Object** and this component is usually followed by tParseRecordSet.

### Use PreparedStatement
Select this check box if you want to query the database using a PreparedStatement. In the **Set PreparedStatement Parameter** table, define the parameters represented by “?” in the SQL instruction of the **Query** field in the **Basic Settings** tab.

- **Parameter Index:** Enter the parameter position in the SQL instruction.
- **Parameter Type:** Enter the parameter type.
- **Parameter Value:** Enter the parameter value.

*Note:*
This option is very useful if you need to execute the same query several times. Performance levels are increased.

### Commit every
Number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and above all better performance on executions.

**JDBC url**
Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.
• **Standard**: Use the standard way to access the Redshift database.

• **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Before selecting this option, ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.

This option is available only when **Use an existing connection** check box is not selected from the **Basic settings**.

---

**tStat Catcher Statistics**

Select this check box to collect log data at the component level.

---

**Global Variables**

**Global Variables**

**QUERY**: the query statement being processed. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](https://www.talend.com/).

---

**Usage**

**Usage rule**

This component offers the flexibility benefit of the database query and covers all possible SQL queries.

**Dynamic settings**

Click the `[+>` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the **Use an existing connection** check box is selected in the **Basic settings** view. Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see **Reading data from databases through context-based dynamic connections** on page 2446 and **Reading data from different MySQL databases using dynamically loaded connection parameters** on page 497. For more information on **Dynamic**
**Limitation**

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the **Install** button on the **Component** tab view. You can also find out and add all missing JARs easily on the **Modules** tab in the **Integration** perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

---

**Related scenarios**

For similar scenarios, see:

- **Combining two flows for selective output** on page 2503
- **Procedure** on page 622
- **Removing and regenerating a MySQL table index** on page 2497
tRedshiftUnload

Unloads data on Amazon Redshift to files on Amazon S3.

This component runs a specified query in Amazon Redshift and then unloads the result of the query to one or more files on Amazon S3.

**tRedshiftUnload Standard properties**

These properties are used to configure tRedshiftUnload running in the Standard Job framework.

The Standard tRedshiftUnload component belongs to the Cloud and the Databases families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either Built-In or Repository.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>Built-In: No property data stored centrally.</td>
</tr>
<tr>
<td></td>
<td>Repository: Select the repository file in which the properties are stored. The database connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Host</td>
<td>Type in the IP address or hostname of the database server.</td>
</tr>
<tr>
<td>Port</td>
<td>Type in the listening port number of the database server.</td>
</tr>
<tr>
<td>Database</td>
<td>Type in the name of the database.</td>
</tr>
<tr>
<td>Schema</td>
<td>Type in the name of the schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Type in the database user authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional JDBC properties for the connection you are creating. The properties are separated by ampersand &amp; and each property is a key-value pair. For example, ssl=true &amp; sslfactory=com.amazon.redshift.ssl.NonValidatingFactory, which means the connection will be created using SSL.</td>
</tr>
<tr>
<td>Table Name</td>
<td>Type in the name of the table from which the data will be read.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.</td>
</tr>
<tr>
<td><strong>Built-In:</strong> You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td><strong>Repository:</strong> You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
<td></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-In** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Query Type** and **Query**

Enter the database query paying particularly attention to the proper sequence of the fields in order to match the schema definition.

Double-escape each simple quotation marks in the query. For example,

```sql
SELECT name, birth,"Add" FROM my_table WHERE birth between '2018-01-01 00:00:00' and '2019-01-01 00:00:00'
```

**Guess Query**

Click the button to generate the query which corresponds to the table schema in the **Query** field.

**Use an existing S3 connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

**Access Key**

Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit **Getting Your AWS Access Keys**.

This option is not available if **Use an existing S3 connection** is selected.

**Secret Key**

Specify the Secret Access Key, constituting the security credentials in combination with the access Key.

To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

This option is not available if **Use an existing S3 connection** is selected.

**Assume Role**

Select this check box and specify the values for the following parameters used to create a new assumed role session.
- **IAM Role ARNs chains**: a series of chained roles, which may belong to other accounts, that your cluster can assume to access resources.
  You can chain a maximum of 10 roles.
- **Role ARN**: the Amazon Resource Name (ARN) of the role to assume.

This option is not available if **Use an existing S3 connection** is selected.

For more information on IAM Role ARNs chains, see Authorizing Redshift service.

<table>
<thead>
<tr>
<th>Bucket</th>
<th>Type in the name of the Amazon S3 bucket, namely the top level folder, to which the data is unloaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key prefix</td>
<td>Type in the name prefix for the unload files on Amazon S3. By default, the unload files are written per slice of the Redshift cluster and the file names are written in the format <code>&lt;object_path&gt;/&lt;name_prefix&gt;&lt;slice-number&gt;_part_&lt;file-number&gt;</code>.</td>
</tr>
</tbody>
</table>

### Advanced settings

| File type     | Select the type of the unload files on Amazon S3 from the list:  
|---------------|---------------------------------------------------------------------|
|               | - **Delimited file or CSV**: a delimited/CSV file.  
|               | - **Fixed width**: a fixed-width file.  |
| Fields terminated by | Enter the character used to separate fields.  
|                 | This field appears only when **Delimited file or CSV** is selected from the **File type** list.  |
| Enclosed by    | Select the character in a pair of which the fields are enclosed.  
|                 | This list appears only when **Delimited file or CSV** is selected from the **File type** list.  |
| Fixed width mapping | Enter a string that specifies a user-defined column label and column width between double quotation marks. The format of the string is:  
|                  | `ColumnLabel1:ColumnWidth1,ColumnLabel2:ColumnWidth2,...`.  
|                  | Note that the column label in the string has no relation to the table column name and it can be either a text string or an integer. The order of the label/width pairs must match the order of the table columns exactly.  
<p>|                  | This field appears only when <strong>Fixed width</strong> is selected from the <strong>File type</strong> list.  |
| Compressed by  | Select this check box and from the list displayed select the compression type of the files.  |
| Encrypt       | Select this check box to encrypt unload file(s) using Amazon S3 client-side encryption. In the <strong>Encryption key</strong> field displayed, enter the encryption key used to encrypt the unload file(s).  |</p>
<table>
<thead>
<tr>
<th>tRedshiftUnload</th>
<th>Note that only a base64 encoded AES 128-bit or AES 256-bit envelope key is supported. For more information, see Unloading Encrypted Data Files. This option is not available if <strong>Use an existing S3 connection</strong> is selected.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify null string</td>
<td>Select this check box and from the list displayed select a string that represents a null value in unload files.</td>
</tr>
<tr>
<td>Escape</td>
<td>Select this check box to place an escape character () before every occurrence of the following characters for CHAR and VARCHAR columns in the delimited unload files: linefeed (\n), carriage return (\r), the delimiter character specified for the unloaded data, the escape character (), a quote character (&quot; or &quot;).</td>
</tr>
<tr>
<td>Overwrite s3 object if exist</td>
<td>Select this check box to overwrite the existing Amazon S3 object files.</td>
</tr>
<tr>
<td>Parallel</td>
<td>Select this check box to write data in parallel to multiple unload files on Amazon S3 according to the number of slices in the Redshift cluster.</td>
</tr>
</tbody>
</table>
| JDBC url | Select a way to access to an Amazon Redshift database from the **JDBC url** drop-down list.  
  - **Standard**: Use the standard way to access the Redshift database.  
  - **SSO**: Use the IAM Single Sign-ON (SSO) authentication way to access the Redshift Database. Before selecting this option, ensure that the IAM role added to your Redshift cluster has appropriate access rights and permissions to this cluster. You can ask the administrator of your AWS services for more details.  
  
  This option is available only when **Use an existing connection** check box is not selected from the **Basic settings**. |
| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
  
  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
  
  To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
  
  For further information about variables, see [Talend Studio User Guide](#). |
|------------------|--------------------------------------------------------------------------------------------------|
### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component covers all possible SQL queries for the Amazon Redshift database.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Related Scenario

For a related scenario, see Loading/unloading data to/from Amazon S3 on page 2970.
**tReplace**

Cleanses all files before further processing.
Carries out a Search & Replace operation in the input columns defined.

**tReplace Standard properties**

These properties are used to configure tReplace running in the Standard Job framework.
The Standard tReplace component belongs to the Processing family.
The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| • View schema: choose this option to view the schema only.
| • Change to built-in property: choose this option to change the schema to Built-in for local changes.
| • Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
| Two read-only columns, Value and Match are added to the output schema automatically. |

| Built-In: You create and store the schema locally for this component only. |

| Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

| Simple Mode Search / Replace | Click the button to add as many conditions as needed. The conditions are performed one after the other for each row.
| Input column: Select the column of the schema the search & replace is to be operated on
| Search: Type in the value to search in the input column
| Replace with: Type in the substitution value.
| Whole word: Select this check box if the searched value is to be considered as whole.
| Case sensitive: Select this check box to care about the case. |
Cleaning up and filtering a CSV file

This Job searches and replaces various typos and defects in a csv file then operates a column filtering before producing a new csv file with the final output.
Drop the following components from the Palette onto the design workspace: **tFileInputDelimited**, **tReplace**, **tFilterColumn** and **tFileOutputDelimited**.

Connect the components using **Main Row** connections via a right-click each component.

Select the **tFileInputDelimited** component and set the input flow parameters.

- **File**: A simple csv file stored locally. The **Row Separator** is a carriage return and the **Field Separator** is a semi-colon. In the **Header** is the name of the column, and no **Footer** nor **Limit** are to be set.
- The file contains characters such as: *t, ,* or Nikson which we want to turn into Nixon, and *street*, which we want to turn into *Street*.

<table>
<thead>
<tr>
<th>Street</th>
<th>FirstName</th>
<th>Name</th>
<th>Amount</th>
</tr>
</thead>
<tbody>
<tr>
<td>street</td>
<td>John</td>
<td>Kennedy</td>
<td>98.30$</td>
</tr>
<tr>
<td>street</td>
<td>Richad</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>street</td>
<td>Richard</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>street</td>
<td>toto</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>street</td>
<td>Richard</td>
<td>Nikson</td>
<td>78.23$</td>
</tr>
<tr>
<td>street</td>
<td>Georges</td>
<td><em>t</em> bush</td>
<td>99.99$</td>
</tr>
</tbody>
</table>

The schema for this file is built in also and made of four columns of various types (string or int).

Now select the **tReplace** component to set the search & replace parameters.

- The schema can be synchronized with the incoming flow.
- Select the **Simple mode** check box as the search parameters can be easily set without requiring the use of regexp.
- Click the plus sign to add some lines to the parameters table.
- On the first parameter line, select **Amount** as **InputColumn**. Type "." in the **Search** field, and ",," in the **Replace** field.
• On the second parameter line, select Street as InputColumn. Type “street” in the Search field, and “Street” in the Replace field.
• On the third parameter line, select again Amount as InputColumn. Type “$” in the Search field, and “£” in the Replace field.
• On the fourth parameter line, select Name as InputColumn. Type “Nikson” in the Search field, and “Nixon” in the Replace field.
• On the fifth parameter line, select Firstname as InputColumn. Type “*t” in the Search field, and replace them with nothing between double quotes.
• The advanced mode isn’t used in this scenario.
• Select the next component in the Job, tFilterColumn.

The tFilterColumn component holds a schema editor allowing to build the output schema based on the column names of the input schema. In this use case, add one new column named empty_field and change the order of the input schema columns to obtain a schema as follows: empty_field, Firstname, Name, Street, Amount.
• Click OK to validate.

Set the tFileOutputDelimited properties manually.
• The schema is built-in for this scenario, and comes from the preceding component in the Job.
• Save the Job and press F6 to execute it.
The first column is empty, the rest of the columns have been cleaned up from the parasitical characters, and Nikson was replaced with Nixon. The street column was moved and the decimal delimiter has been changed from a dot to a comma, along with the currency sign.
tReplaceList

tReplaceList
Cleanses all files before further processing.
Carries out a Search and Replace operation in the input columns defined based on an external
lookup.

tReplaceList Standard properties
These properties are used to configure tReplaceList running in the Standard Job framework.
The Standard tReplaceList component belongs to the Data Quality family.
The component in this framework is available in all Talend products.
Basic settings
Schema and Edit schema

A schema is a row description, it defines the number
of fields to be processed and passed on to the next
component. The schema is either Built-in or stored remotely
in the Repository.
Two read-only columns, Value and Match are added to the
output schema automatically.
Warning:
The data Type defined in the schemas must be consistent,
ie., an integer can only be replaced by another integer
using an integer as a look up field. Values of one type
cannot be replaced by values of another type.

Built-in: The schema will be created and stored locally for
this component only. Related topic: see Talend Studio User
Guide.
Repository: The schema already exists and is stored in the
Repository, hence can be reused in various projects and job
designs. Related topic: see Talend Studio User Guide.
Lookup search column

Select the column to be searched in the lookup schema.

Lookup replacement column

Select the column where the replacement values are stored.

Column options

Select the columns of the main flow where the replacement
is to be carried out.

Advanced settings
tStat Catcher Statistics

Select this check box to collect log data at the component
level.

3031


Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

Usage

| Usage rule | tReplaceList is an intermediary component. It requires an input flow and an output component. |

Replacing state names with their two-letter codes

The following Job searches and replaces a list of states with their corresponding two-letter codes. The relevant codes are taken from a reference file placed as lookup flow in the Job.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: two tFileInputDelimited components, a tReplaceList and a tLogRow.
2. Connect the two tFileInputDelimited components to the tReplaceList component using Row > Main connections. Note that the link between the reference input component (the second tFileInputDelimited) and the tReplaceList component appears as a lookup row.
3. Connect the tReplaceList component to the tLogRow component using a Row > Main connection.
Configuring the components

Procedure

1. Double-click the first tFileInputDelimited component to open its Basic settings view and set the parameters of the main input flow, including the path and name of the file to read and the number of header rows to skip.

   ![tFileInputDelimited component](image)

   In this example, the main input file provides a list of people names and US state names. The following shows an extract of the file content:

   ```
   name;state
   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
   Dwight Roosevelt;Mississippi
   Franklin Grant;Nebraska
   ```

2. Click the [...] button next to Edit schema to open the Schema dialog box and set the input schema. According to the structure of the main input file, the input schema should contain two columns: *name* and *state*. 
When done, click OK to close the dialog box and propagate the changes to the next component.

3. Define the properties of the second tFileInputDelimited component similarly.

In this example, the reference input file provides a list of states and their two-letter codes. Accordingly, the reference input schema should have two columns: state and code.

4. Double-click the tReplaceList component to open its Basic settings view to set the operation to carry out.
5. From the **Lookup search column** list, select the column to be searched. In this use case, we want to carry out a search on the *state* column.

6. From the **Lookup replacement column** list, select the column containing the replacement values, *code* for the two-letter state codes in this example.

7. In the **Column options** table, select **Replace** check box for the *states* column, to replace the state names with their corresponding codes.

8. In the **tLogRow** component, select the **Table** check box for a better readability of the output.

### Executing the Job

#### Procedure

Save the Job and press **F6** to execute it.

The state names have been replaced with their respective two-letter codes.
tReplicate

Duplicates the incoming schema into two identical output flows.
This component performs different operations on the same schema.

tReplicate Standard properties

These properties are used to configure tReplicate running in the Standard Job framework.
The Standard tReplicate component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>

Global Variables

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|---|---|
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is not startable (green background), it requires an Input component and an output component.</th>
</tr>
</thead>
</table>

Connections

Outgoing links (from this component to another):
- **Row**: Main.
- **Trigger**: Run if; On Component Ok; On Component Error.

Incoming links (from one component to this one):
- **Row**: Main; Reject;

For further information regarding connections, see Talend Studio User Guide.

Replicating a flow and sorting two identical flows respectively

The scenario describes a Job that reads an input flow which contains names and states from a CSV file, replicates the input flow, then sorts the two identical flows based on name and state respectively, and displays the sorted data on the console.

Setting up the Job

Procedure

1. Drop the following components from the Palette to the design workspace: one tFileInputDelimited component, one tReplicate component, two tSortRow components, and two tLogRow components.
2. Connect tFileInputDelimited to tReplicate using a Row > Main link.
3. Repeat the step above to connect tReplicate to two tSortRow components respectively and connect tSortRow to tLogRow.
4. Label the components to better identify their functions.

**Configuring the components**

**Procedure**

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view in the **Component** tab.

2. Click the [...] button next to the **File name/Stream** field to browse to the file from which you want to read the input flow. In this example, the input file is **Names&States.csv**, which contains two columns: *name* and *state*.

   ```text
   name;state
   Andrew Kennedy;Mississippi
   Benjamin Carter;Louisiana
   Benjamin Monroe;West Virginia
   Bill Harrison;Tennessee
   Calvin Grant;Virginia
   Chester Harrison;Rhode Island
   Chester Hoover;Kansas
   Chester Kennedy;Maryland
   Chester Polk;Indiana
   Dwight Nixon;Nevada
   Dwight Roosevelt;Mississippi
   Franklin Grant;Nebraska
   ```

3. Fill in the **Header**, **Footer** and **Limit** fields according to your needs. In this example, type in **1** in the **Header** field to skip the first row of the input file.
4. Click **Edit schema** to define the data structure of the input flow.

![Edit schema](image)

5. Double-click the first **tSortRow** component to open its **Basic settings** view.

![tSortRow settings](image)

6. In the **Criteria** panel, click the [+ ] button to add one row and set the sorting parameters for the schema column to be processed. To sort the input data by name, select **name** under **Schema column**. Select **alpha** as the sorting type and **asc** as the sorting order. For more information about those parameters, see **tSortRow Standard properties** on page 3465.

7. Double-click the second **tSortRow** component and repeat the step above to define the sorting parameters for the state column.
8. In the **Basic settings** view of each **tLogRow** component, select **Table** in the **Mode** area for a better view of the Job execution result.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.

The data sorted by name and state are both displayed on the console.
tREST

Serves as a REST Web service client.

The tREST component sends HTTP requests to a REpresentational State Transfer (REST) Web service provider and gets responses correspondingly.

**tREST Standard properties**

The Standard tREST component belongs to the Internet family.

<table>
<thead>
<tr>
<th>Basic settings</th>
</tr>
</thead>
</table>
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component. This component always uses a built-in, read-only schema that contains two columns:
- **Body**: stores the result from the server end.
- **ERROR_CODE**: stores the HTTP status code from the server end when an error occurs during the invocation process. The specific meanings of the errors codes are subject to definitions of your Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_status_codes.

Click **Edit Schema** to view the schema structure. |
| **Warning:** | Changing the schema type may result in loss of the schema structure and therefore failure of the component. |
| **URL** | Type in the URL address of the REST Web server to be invoked. |
| **HTTP Method** | From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions:
- **GET**: retrieves data from the server end based on the given parameters.
- **POST**: creates and uploads data based on the given parameters. |
REST
- **PUT**: updates data based on the given parameters, or if the data does not exist, creates it.
- **DELETE**: removes data based on the given parameters.

### HTTP Headers
Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation.

For the specific definitions of HTTP headers, consult your REST Web service provider. For reference information, visit en.wikipedia.org/wiki/List_of_HTTP_headers.

### HTTP Body
Type in the payload to be uploaded to the server end when the **POST** or **PUT** action is selected.

### Advanced settings

#### tStatCatcher Statistics
Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

#### Global Variables
**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see **Talend Studio User Guide**.

### Usage

#### Usage rule
Use this component as a REST Web service client to communicate with a REST Web service provider. It must be linked to an output component.

#### Limitation
JRE 1.6 must be running for this component to work properly.

## Creating and retrieving data by invoking REST Web service

This scenario describes a simple Job that invokes a REST Web service to create a new customer record on the server end and then retrieve the customer information. When executed, the Job displays relevant information on the **Run** console.

- Drop the following components from the **Palette** onto the design workspace: two **tREST** components and two **tLogRow** components, and label the two **tREST** components to best describe the actions to perform.
- Connect each **tREST** to one **tLogRow** using a **Row > Main** connection.
• Connect the first tREST to the second tREST using a Trigger > OnSubjobOK connection.

![Diagram of tREST connections](image)

• Double click the first tREST component to open its Basic settings view.

![Basic settings view of tREST](image)

**Basic settings**

- **Schema**: Built-In
- **URL**: `http://192.168.0.30:8080/customerservice/customers`

**HTTP Method**: POST

**HTTP Headers**

<table>
<thead>
<tr>
<th>name</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>Content-Type</td>
<td>application/xml</td>
</tr>
</tbody>
</table>

**HTTP Body**: 

```
<Customer><name>Steven</name></Customer>
```

**Note:**

If you want to include double quotation marks in your payload, be sure to use a backslash escape character before each of the quotation marks. In this use case, for example, type in `<Customer><name>\"Steven\"</name></Customer>` if you want to enclose the name Steven in a pair of double quotation marks.

• Double click the second tREST component to open its Basic settings view.

---

3043
• Fill the **URL** field with the same URL.
• From the **HTTP Method** list, select **GET** to send an HTTP request for retrieving the existing records.
• In the **Basic settings** view of each **tLogRow**, select the **Print component unique name in front of each output row** and **Print schema column name in front of each value** check boxes for better identification of the output flows.

![Image of tLogRow_1]

- **Basic settings**
  - **Schema**
  - **Mode**
    - Basic
    - Table (print values in cells of a table)
    - Vertical (each row is a key/value list)
  - **Field Separator** ‘|’
  - **Print header**
  - **Print component unique name in front of each output row**
  - **Print schema column name in front of each value**
  - **Use fixed length for values**

• Save your Job and press **F6** to launch it.

The console shows that the first **tREST** component sends an HTTP request to the server end to create a new customer named **Steven**, and the second **tREST** component successfully reads data from the server end, which includes the information of the new customer you just created.
tRESTClient

Interacts with RESTful Web service providers by sending HTTP and HTTPS requests using CXF (JAX-RS) getting the corresponding responses.

This component integrates well with  *Talend Runtime*  to get HTTPS support, with more QoS features to be supported in time.

**tRESTClient Standard properties**

These properties are used to configure tRESTClient running in the Standard Job framework.

The Standard tRESTClient component belongs to the ESB family.

The component in this framework is available in all  *Talend products*.  

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>URL</strong></td>
<td>Type in the URL address of the REST server to be invoked. When the <em>Use Service Locator</em> check box is selected, this field will not show and the URL of the REST server will be obtained from the Service Locator server automatically.</td>
</tr>
</tbody>
</table>
| **Relative Path** | Enter the relative path of the REST server to be invoked. For example, if you want to access  *http://localhost:8888/services/Customers/list*:  
If *Use Service Locator* is disabled: You can enter any of the first part of the address in the URL field, and the second part in the Relative Path field. For example, you can enter http://localhost:8888 in URL and /services/Customers/list in Relative Path.  
You can also enter the full path of the REST server in URL and leave Relative Path blank.  
If *Use Service Locator* is enabled: The URL part will be given by the Service Locator. In this case, you need to know the URL part, and specify the rest part in Relative Path. This depends on the service you request. For example, on tRESTRequest, you specify REST Endpoint as http://localhost:8888/services and enable Use Service Locator. Then, if you want to use this service, on tRESTClient side, you should specify /customers/list in Relative Path.  
**Warning**: When using relative path, you should specify at least one sub-directory in the URL field instead of only host:port to avoid compiling issues. For example, use http://localhost:8888/services instead of http://localhost:8888. |
| **HTTP Method** | From this list, select an HTTP method that describes the desired action. The specific meanings of the HTTP methods are subject to definitions of your Web service provider. Listed below are the generally accepted HTTP method definitions:  
- GET: retrieves data from the server end based on the given parameters. |
<table>
<thead>
<tr>
<th>RESTClient</th>
<th></th>
</tr>
</thead>
</table>
| **- POST**: uploads data to the server end based on the given parameters.  
**- PUT**: updates data based on the given parameters, or if the data does not exist, creates it.  
**- PATCH**: modifies data partially based on the given parameters.  
**- DELETE**: removes data based on the given parameters.  |  |
| **Content Type** | Select XML, JSON, or FORM according to the media type of the content to be uploaded to the server end.  
This list appears only when you select the POST, PUT, or PATCH HTTP method.  |
| **Accept Type** | Select the media type the client end is prepared to accept for the response from the server end.  
Available options are XML, JSON, and ANY. When ANY is selected, the response message can be of any type and will be transformed into a string.  |
| **Query parameters** | Specify the URI query parameters in the form of name-value pairs.  
This option is mostly used with the GET method.  |
| **Schema and Edit Schema** | A schema is a row description, it defines the number of fields that will be processed and passed on to the next component.  
This component uses three built-in, read-only schemas.  
Click Edit Schema to view the schema structure.  |
| **Warning:**  
Changing the schema type may result in loss of the schema structure and therefore failure of the component.  |
| **Input Schema** | Schema for the input data. This schema contains two columns:  
- **body**: stores the content of structured input data  
- **string**: stores the input content when it is, or is handled as, a string.  |
| **Response Schema** | Schema for server response. This schema is passed onto the next component via a Row > Response link, and it contains three columns:  
- **statusCode**: stores the HTTP status code from the server end.  
- **body**: stores the content of a structured response from the server end.  
- **string**: stores the response content from the server end when it is, or is handled as, a string.  |
| **Error Schema** | Schema for error information. This schema is passed onto the next component via a Row > Error link, and it contains two columns:  
- **errorCode**: stores the HTTP status code from the server end when an error occurs during the invocation |
- **errorMessage**: stores the error message corresponding to the error code.

<table>
<thead>
<tr>
<th>Use Service Locator</th>
<th>Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use Service Activity Monitor</td>
<td>Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.</td>
</tr>
</tbody>
</table>
| Use Authentication | Select this check box if authentication is required on the REST server end. Select the authentication type from:  
  - **Basic HTTP**: Fill the **Username** and **Password** fields with your credentials.  
  - **HTTP Digest**: Fill the **Username** and **Password** fields with your credentials.  
  - **SAML Token (ESB runtime only)**: Fill the **Username** and **Password** fields with your credentials.  
  - **OAuth2 Bearer**: Fill the **Bearer Token** field with a base64-encoded credential string.  
  To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| Use Business Correlation | Select this check box to create a correlation ID in this component. You can specify a correlation ID in the **Correlation Value** field. In this case the correlation ID will be passed on to the service it calls so that chained service calls will be grouped under this correlation ID. If you leave this field empty, this value will be generated automatically at runtime. When this option is enabled, **tRESTClient** will also extract the correlation ID from the response header and store it in the component variable for further use in the flow. |
| Die on error | This check box is selected to kill the Job when an error occurs. Clear the check box to skip the row on error and complete the process for error-free rows. |

### Advanced settings

<table>
<thead>
<tr>
<th>Log messages</th>
<th>Select this check box to log the message exchange between the service provider and the consumer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Enable WebClient Operation Reporting</td>
<td>If this check box is selected, a CXF endpoint property will be set on the client side which may be used by some outgoing</td>
</tr>
</tbody>
</table>
CXF metrics interceptors, to track requests to services using their URL's.

The property set is `org.apache.cxf.resource.operation.name` and it contains service URL together with the HTTP method name, for example `GET:http://example.com:8080/service/`

If this check box is not selected, the property will not be set and some metrics will not be counted, which may increase the performance.

### Convert Response To DOM Document

Select this check box to convert the response from the server to document type.

Clear this check box if you want the response to be handled as a string.

### Convert Types To Strings

This option appears when `Content Type` is JSON, or `Accept Type` is JSON or any. Select this check box to convert all values in JSON to string between quotation marks. For example, with this option enabled, the JSON data:

```json
"root": {
  "test": 111
}
```

will be changed to:

```json
"root": {
  "test": "111"
}
```

### Drop JSON Request Root

This option appears when `HTTP Method` is POST, PUT or PATCH and `Content Type` is JSON. Select this check box to drop root JSON elements.

### Wrap JSON Response

This option appears and is enabled by default when JSON is selected from the `Accept Type` list in the Basic settings view.

With this check box selected, the response is wrapped with a root element. Clear this check box to remove the root element from the response.

### HTTP Headers

Type in the name-value pair(s) for HTTP headers to define the parameters of the requested HTTP operation.

For the specific definitions of HTTP headers, consult your REST Web service provider. For reference information, visit [en.wikipedia.org/wiki/List_of_HTTP_headers](en.wikipedia.org/wiki/List_of_HTTP_headers).

### Disable chunked encoding

This option appears when `HTTP Method` is POST, PUT or PATCH. Select this check box to disable encoding the payload as chunks.

### Service Locator Customer Properties

This option appears when `Use Service Locator` is enabled in the Basic settings tab. Click '+' to add as many properties as needed to the table. Enter the name and the value of each property in the `Property Name` field and the `Property Value` field respectively to identify the service.

### Service Activity Customer Properties

This option appears when `Use Service Activity Monitor` is enabled in the Basic settings tab. Click '+' to add as many properties as needed to the table. Enter the name and the
value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service.

### Connection timeout

Set the amount of time, in seconds, that the client will attempt to establish a connection before it times out. If set to 0, the client will continue to attempt to open a connection indefinitely. (default: 30)

This option only works in the Studio and for DI Job use cases. For ESB Deployments to Talend Runtime, this parameter will have no effect when the component is deployed in runtime. In the configuration file `<TalendRuntimePath>/container/etc/org.apache.cxf.http.conduits-common.cfg`, you need a URL which covers your service, for example, `url = http://.*` to handle both HTTP and HTTPS requests, and specify the `client.ConnectionTimeout` parameter in milliseconds in this HTTP Conduit file. If you need to use the **Receive timeout** option, specify the `client.ReceiveTimeout` in milliseconds too.

### Receive timeout

Set the amount of time, in seconds, that the client will wait for a response before it times out. If set to 0, the client will wait indefinitely. (default: 60) This option works similar to the **Connection timeout** for Studio, DI Use cases and ESB Runtime (OSGi / Microservice Deployments). For how to use it after the component is deployed in runtime or in Talend Administration Center, see the **Connection timeout** option.

### Use HTTP proxy

Select this check box if you are using a proxy server. Once selected, you need to provide the connection details: host, port, username and password.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>the number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>HEADERS</strong></td>
<td>the HTTP response headers. This is a Flow variable and it returns a list of HTTP response header values.</td>
</tr>
<tr>
<td><strong>CORRELATION_ID</strong></td>
<td>the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press `Ctrl + Space` to access the variable list and choose the variable to use from it.
### Usage

**Usage rule**

This component is used as a RESTful Web service client to communicate with a RESTful service provider, with the ability to input a request to a service into a Job and return the Job result as a service response. Depending on the actions to perform, it usually works as a start or middle component in a Job or subjob.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to turn on or off the Use Authentication or Use HTTP proxy option dynamically at runtime. You can add two rows in the table to set both options.

Once a dynamic parameter is defined, the corresponding option becomes highlighted and unusable in the Basic settings view or Advanced settings view.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Connections**

Outgoing links:

- **Row**: Response; Error.
- **Trigger**: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error.

Incoming links:

- **Row**: Main; Reject.
- **Trigger**: Run if; On Subjob Ok; On Subjob Error; On component Ok; On Component Error.

For further information regarding connections, see Talend Studio User Guide.

### Limitation

Using context variables for dynamic endpoint or Service Locator namespace works in the Studio only. It is not supported in Runtime.

---

### Getting user information by interacting with a RESTful service

This scenario describes a three-component Job that retrieves user information based on the user ID from a REST service via HTTP GET and displays the retrieved user information, as well as the message exchange between the client and the server, on the Run console.

**Prerequisites:**

If you are a Talend Open Studio for ESB user, create a Job as described in Using URI Query parameters to explore the data of a database on page 3072, run the Job to expose a REST service, and enter the...
REST service URL in your Web browser, http://localhost:8088/users in this example. You should see information like the following:

```xml
- <users>
  - <user id="1">  
    <first_name>Ronald</first_name>  
    <last_name>Johnson</last_name>  
  </user>
  - <user id="2">  
    <first_name>Theodore</first_name>  
    <last_name>Harding</last_name>  
  </user>
  - <user id="3">  
    <first_name>Bill</first_name>  
    <last_name>Roosevelt</last_name>  
  </user>
</users>
```

If you are not a Talend Open Studio for ESB user, then you need to get from your REST service provider the URL, the data structure, and the required parameters of the REST service you are going to call and make necessary modifications in the scenario configurations accordingly.

**Setting up the Job**

**Procedure**

1. Drop the following components from the Palette onto the design workspace:
   - `tRESTClient`, used to call the REST service and retrieve user information from the server end,
   - `tXMLMap`, used to adapt the tree structure of the REST service, and
   - `tLogRow`, to display the retrieved user information on the Run console.
2. Connect the `tRESTClient` to the `tXMLMap` using a Row > Response connection.
3. Connect the `tXMLMap` to the `tLogRow` using a Row > Main connection, and give it a name, `out` in this example.
4. Label the components to best describe the actions to perform.

**Configuring the components**

**Configuring the service call**

**Procedure**

1. Double-click the `tRESTClient` component to open its Basic settings view.
2. Fill the **URL** field with the URL of the REST service you are going to invoke, "http://localhost:8088/users" in this example. Note that the URL provided in this use case is for demonstration purposes only and not a live address.

3. From the **HTTP Method** list, select **GET** to send an HTTP request for retrieving the existing records.
   - From the **Accept Type** list, select the type the client end is prepared to accept for the response from the server end, **XML**. Leave the rest of the settings as they are.

4. Click the [+ ] button beneath the **Query parameters** table to add two parameters, *from* and *to*, and set both parameters to 2, to get the information of the user with the ID of 2.
   - Alternatively, you can query the information of the user with the ID of 2 by adding **?from=2&to=2** to the service URL.

5. In the **Advanced settings** view of the tRESTClient component, select the **Log messages** and the **Convert Response To DOM Document** check boxes to log the message exchange to the server and convert the response from the server to document type.

**Mapping the service structure and displaying the retrieved user information**

**Procedure**

1. Double-click the tXMLMap component to open the Map Editor.

2. If you selected **XML** in the **Accept Type** list of the tRESTClient component, define the input XML tree structure according to the service structure.
   - a) In the input table, right-click the default root node of the body column, select **Rename** from the contextual menu, and rename it to **users**.
b) Right-click the users node, select **Create Sub-Element** from the contextual menu, and create sub-element named user. Set user as the loop element because the XML structure of the Web service to be invoked is looped on this element.

c) Right-click the user node, select **Create Attribute** from the contextual menu, and enter id in the **Create New Attribute** dialog box to create an attribute named id for the user node.

d) Right-click the user node again, select **Create Sub-Element** from the contextual menu, and enter first_name in the **Create New Element** dialog box to create an sub-element named first_name for the user node.

Repeat this operation to create another sub-element under the user node, last_name.

e) Drop the id, first_name and last_name columns from the input table to the output table, and then click OK to validate the mapping and close the Map Editor.

If you selected **JSON** in the **Accept Type** list of the **tRESTClient** component, the response from the server end will be sent back in JSON format and converted to document type. In this example, the converted response structure looks like the following:

```xml
<root>
  <users>
    <user>
      <id>2</id>
      <first_name>Theodore</first_name>
      <last_name>Harding</last_name>
    </user>
  </users>
</root>
```
Note that the `<root>` element is removed if the **Wrap JSON Response** check box is cleared in the **Advanced settings** of the **tRESTClient** component.

Define the input XML tree structure accordingly and map it with the output data flow in a similar manner as described above.

3. Double-click the **tLogRow** component to open its **Basic settings** view.

4. Click the **Sync columns** button to make sure the component schema is synchronized with the output schema of the **tXMLMap** component.

5. In the **Mode** field, select the **Table** option to display the GET result in table cells.
**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the Run console to launch the Job.

   The console shows that the **tRESTClient** component successfully reads the user information from the server end corresponding to the specified user ID.

   If you selected **XML** in the **Accept Type** list of the **tRESTClient** component, the execution result will be:

   ![XML Execution Result]

   If you selected **JSON** in the **Accept Type** list of the **tRESTClient** component, the execution result will be:

   ![JSON Execution Result]
Updating user information by interacting with a RESTful service

This scenario describes a three-component Job that updates the information of a list of users to a remote database through a REST service using the HTTP POST method. When executed, the Job displays the client-server message exchange information on the Run console.
The user information to be updated to the server is stored in a CSV file, which looks like the following:

<table>
<thead>
<tr>
<th>id</th>
<th>first_name</th>
<th>last_name</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>John</td>
<td>Smith</td>
</tr>
<tr>
<td>2</td>
<td>Martin</td>
<td>Reagan</td>
</tr>
<tr>
<td>3</td>
<td>James</td>
<td>White</td>
</tr>
<tr>
<td>4</td>
<td>Jenny</td>
<td>Jackson</td>
</tr>
<tr>
<td>5</td>
<td>Robert</td>
<td>Thomson</td>
</tr>
</tbody>
</table>

**Prerequisites:**

If you are a *Talend Open Studio for ESB* user, create a Job as described in *Using a REST service to accept HTTP POST requests* on page 3080 and run the Job as a REST server to expose a REST service that accepts HTTP POST requests. Upon execution of the Job, the console displays the service implementation information, including the service endpoint URL, which is http://localhost:8045/users in this example. If you enter http://localhost:8045/users?_wadl in your Web browser, you should see the service definition information like the following:

```
<application>
  <grammars/>
  <resources base="http://localhost:8045/users">
    <resource path="/"/>
      <resource path="post/{id}/{first_name}/{last_name}"/>
        <param name="last_name" style="template" type="xs:string"/>
        <param name="id" style="template" type="xs:int"/>
        <param name="first_name" style="template" type="xs:string"/>
    </resource>
    <method name="POST">
      <request/>
      <response>
        <representation mediaType="application/xml"/>
        <representation mediaType="text/xml"/>
        <representation mediaType="application/json"/>
      </response>
    </method>
  </resource>
</resources>
</application>
```

If you are not a *Talend Open Studio for ESB* user, then you need to get the service-related information from your REST service provider including the URL, the resource path, and the data structure, and make necessary modifications in the scenario configurations accordingly.
## Setting up the Job

### Procedure

1. Create a Job and add the following components by typing their names in the design workspace or drop them from the Palette:
   - `tFileInputDelimited`, to read user information of a local file,
   - `tXMLMap`, to adapt the input structure to the REST service structure, and
   - `tRESTClient`, used to call the REST service to send data to the remote database.

2. Connect the `tFileInputDelimited` to the `tXMLMap` using a `Row > Main` connection.

3. Connect the `tXMLMap` to the `tRESTClient` using a `Row > Main` connection, and give the output flow a name, `request` in this example.

4. Label the components to best describe the actions to perform.

### Configuring the components

#### Configuring the input data and the structure mappings

### Procedure

1. Double-click the `tFileInputDelimited` component to open its **Basic settings** view.

   2. Specify the input file in the **File name** field, fill the **Header** field with `1` to skip the header row, and keep the rest parameters as they are.

   3. Click the ` [...] ` button next to **Edit schema** to open the **Schema** dialog box, and edit the input schema as follows:
      - `id`, type Integer, 2 characters long, set as the key column
      - `first_name`, type String
      - `last_name`, type String
4. Double-click the tXMLMap component to open the Map Editor.
5. Rename the root node in the output table: right-click the node, select Rename from the contextual menu, and specify a new name in the pop-up dialog box, user in this example.
6. Select all the three columns in the input table and drop them onto the user node, and select the Create as sub-element of target node option from the pop-up dialog box to set these columns as sub-elements of the user node. When done, click OK to validate the mappings and close the Map Editor.
Configuring the service call

Procedure

1. Double-click the tRESTClient component to open its Basic settings view.

![Send User Info (HTTP POST) (tRESTClient_1)](image)

2. Fill the URL field with the URI location where the REST service is accessible, "http://localhost:8088/users" in this example.

3. In the Relative Path field, enter the resource path, "/post/" + row1.id + "/" + row1.first_name + "/" + row1.last_name in this example. This will send the data from the input row to the server end via the resource path.

4. From the HTTP Method list, select GET to send an HTTP request for retrieving the existing records.
   - From the Accept Type list, select the type the client end is prepared to accept for the response from the server end, XML.

5. In the Advanced settings view of the tRESTClient component, select the Log messages check box to log the message exchange information with the server.
   - Leave the rest of the settings as they are.

Running the Job and checking the result

Press Ctrl+S to save your Job, and press F6 to execute it.

The console displays the client-server exchange information:
The console of the server Job displays the exchange information and the database update result.
ID: 5
Encoding: ISO-8859-1
Http-Method: POST

<user><id>5</id><first_name>Robert</first_name><last_name>Thomson</last_name></user>
tRESTRequest

Receives GET/POST/PUT/PATCH/DELETE requests from the clients on the server end.

tRESTRequest accepts the HTTP and/or HTTPS requests from the clients and supports GET, POST, PUT, PATCH and DELETE HTTP methods.

**Note:**
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the `org.ops4j.pax.web.cfg` file of your Runtime container before deploying the service on it. For more information, see the [Talend ESB Container Administration Guide](#).

**tRESTRequest Standard properties**

These properties are used to configure tRESTRequest running in the Standard Job framework.

The Standard tRESTRequest component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

| REST Endpoint | Fill this field with the URI location where REST-ful web service will be accessible for requests. You can either specify an explicit port number, for example, "http://localhost:8088/services/customers", or use the default port of Talend and specify the relative path only, for example, "/services/customers".

The default port is different depending on the build type or where you run the service:

- To run the service inside Talend Studio: 8090
- To run the service in a Talend Runtime Container: for HTTP 8040 is used for all services, and if HTTPS is enable on Talend Runtime the service is also exposed on 9001.
- To run the service as a Microservice: 8065 |
| REST API Mapping | Click the [+] button beneath the mapping table to add lines to specify HTTP request:

**Output Flow:** Click the [...] button to specify the name of an output flow and set the schema for that output flow in the dialog box afterwards.

The schema is not mandatory, so if you do not need to pass additional parameters to the tRESTRequest component, you can leave the schema empty. However, you will have to populate the schema if you have URI Path parameters set in the URI Pattern field or if you need to add optional request parameters such as URI Query, HTTP Header or Form parameters, to the URI specified in the REST Endpoint field.

Add a schema with the name `body` to get the request body of POST and PUT methods. It supports Document, String, and Byte types. |
If you specify URI parameters in the output flow schema, you might need to define what type of parameter it is in the Comment field of the schema. By default, if you leave the Comment field empty, the parameter is considered as a Path parameter. Below is a list of supported Comment values:

- empty or path corresponds to the default `@PathParam`.
- query corresponds to `QueryParam`.
- form corresponds to `FormParam`.
- header corresponds to `HeaderParam`.
- matrix corresponds to `MatrixParam`.
- multipart corresponds to the CXF specific `Multipart`, representing the request body. It can be used only with POST and PUT HTTP methods.

**Note:**
We recommend you to set the default values of your optional parameters (Header, Query, Form). To do so, fill in the Default columns of the schema.

**HTTP Verb:** Select a HTTP method (GET/POST/PUT/PATCH/OPTIONS/DELETE/HEAD) from the list.

**URI pattern:** Fill this field with REST-ful URIs that describe the resource.

**Consumes:** Select the format type of the consume content that the component will use from XML or JSON, XML, JSON, Form, Multipart and Any in the list when the HTTP method is POST, PUT or PATCH.

**Produces:** When the HTTP method is GET, POST, PUT, PATCH, or DELETE, select the format type of the produce content that the component will use from XML or JSON, XML, JSON, HTML and Any, or select <oneway> in the list to accept one way requests.

**Streaming:** Select this check box to stream the response data by chunks so that the large volumes of data can be processed efficiently.

### Use Service Locator
Select this check box to enable the Service Locator. It maintains the availability of the service to help meet demands and service level agreements (SLAs). Specify the Service namespace and the Service name in the corresponding fields.

### Use Service Activity Monitor
Select this check box to enable the Service Activity Monitor. It captures events and stores this information to facilitate in-depth analysis of service activity and track-and-trace of messages throughout a business transaction. This can be used to analyze service response times, identify traffic patterns, perform root cause analysis and more.

### Use Authentication (ESB runtime only)
Select this check box to enable the authentication option for the current service. This option works in runtime only. Select the authentication type from:

- **Basic HTTP:** The simplest technique for enforcing access controls to web resources using standard fields in the HTTP header.
- **SAML Token:** An XML-based, open-standard data format for exchanging authentication and au
tRESTRequest

**Use Business Correlation**
Select this check box to enable the correlation option so that chained service calls will be grouped under the same correlation ID. **tRESTRequest** will extract the correlation ID from the request header and store it in the component variable for further use in the flow.

If this option is not enabled on the client side, a correlation ID will be generated automatically in **tRESTRequest**.

---

**Advanced settings**

<table>
<thead>
<tr>
<th>Log messages</th>
<th>Select this check box to log the message exchange between the service provider and the consumer.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Wrap JSON Request</td>
<td>Select this check box to wrap the JSON request with a root element.</td>
</tr>
<tr>
<td>Convert JSON values to String in response</td>
<td>Select this check box to convert the JSON values to string format in the response.</td>
</tr>
</tbody>
</table>

**Service Locator Customer Properties**
This option appears when **Use Service Locator** is enabled in the **Basic settings** tab. Click [*] to add as many properties as needed to the table. Enter the name and the value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service.

**Service Activity Customer Properties**
This option appears when **Use Service Activity Monitor** is enabled in the **Basic settings** tab. Click [*] to add as many properties as needed to the table. Enter the name and the value of each property in the **Property Name** field and the **Property Value** field respectively to identify the service.

**tStatCatcher Statistics**
Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

---

**Global Variables**

| Global Variables | **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer. |
|------------------|**URI**: the URI of the REST request. This is a Flow variable and it returns a string. |
|                  |**URI_BASE**: the base URI of the REST request. This is a Flow variable and it returns a string. |
|                  |**URI_ABSOLUTE**: the absolute URI of the REST request. This is a Flow variable and it returns a string. |
|                  |**HTTP_METHOD**: the http method. This is a Flow variable and it returns a string. |
|                  |**ATTACHMENT_HEADERS**: the attachment headers from the REST request. This is a Flow variable and it returns a list of attachment header values. |
|                  |**ATTACHMENT_FILENAMES**: the attachment filenames from the REST request. This is a Flow variable and it returns all attachment filenames. |
### tRESTRequest

**PRINCIPAL_NAME**: the principal name of the REST request. This is a Flow variable and it returns a string.

**CORRELATION_ID**: the correlation ID by which chained service calls will be grouped. This is a Flow variable and it returns a string.

**ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Using a REST service to accept HTTP GET requests and send responses

This scenario applies only to **Talend Open Studio for ESB**, **Talend Data Services Platform** and **Talend Data Fabric**.

This scenario describes the process of accepting an HTTP request from the client, processing it and sending the response back.
Configuring the tRESTRequest component

Procedure

1. Drop the following components from the Palette onto the design workspace: a tRESTRequest, two tXMLMap and two tRESTResponse.

2. Double-click tRESTRequest in the design workspace to display its Basic settings view.

3. Fill the REST Endpoint field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://192.168.0.235:8088/user".

   Note:
   If you want your service to be available on both HTTP and HTTPS, fill the field with a relative path. For example, if you type in "/test", your service will be available on both http://<DefaultHTTPEnpointAddress>/test and https://<DefaultHTTPSEnpointAddress>/test, provided that you have configured your Runtime container to support HTTPS. For more information, see the Talend ESB Container Administration Guide.

4. Click the [+] button to add one line in the REST API Mapping table.
5. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow. In this scenario, the output flow will be named as *GetOneUser*. Then click the [+] button to add a new line *id* to the schema in the dialog box.

6. Click OK to save the schema.

7. Select GET from the list in the HTTP Verb column.

8. Fill the field in the URI Pattern column with "/{id}/".

9. In the same way, add another line in the REST API Mapping table and name this schema *GetUserNumber*. Add a line *string* of *String* type to the schema. Enter *query* in the Comment field to get the number parameter in the request.

Select GET from the list in the HTTP Verb column. Fill the field in the URI Pattern column with "/number".

**Configuring the first tXMLMap component**

**Procedure**

1. Connect tRESTRequest to a tXMLMap using the Row > GetOneUser connection.
2. Double-click tXMLMap in the design workspace to open the Map Editor.
3. Click the [+] button on the top right to add an output and name it as `ResponseUsers`.

4. Click the [+] button on the bottom right to add two columns for the output.
   - Name the first column as `body` and set the **Type** to **Document**.
   - Name the second column as `string` and set the **Type** to **String**.

5. Right-click on the node `root` and select **Create Sub-Element** to create a sub-element. Name the sub-element as `foo` in the popup dialog box.

6. Right-click on the `foo` node created in the previous step and select **As loop element**.

7. Select the `id` column of the `GetOneUser` table to the left and drop it onto the **Expression** field of the `foo` node of the `ResponseUsers` table to the right.

8. Click **OK** to save the settings.

**Configuring the second tXMLMap component**

**Procedure**

1. Connect `tRESTRequest` to the other `tXMLMap` using the **Row > GetUserNumber** connection.
2. Double-click the first `tXMLMap` in the design workspace to open the **Map Editor**.
3. Click the [+] button on the top right to add an output and name it as `ResponseUserNumber`.

4. Click the [+] button on the bottom right to add one column for the output. Name the first column as `body` and set the Type to `Document`.

5. Right-click on the node `root` and select `Create Sub-Element` to create a sub-element. Name the sub-element as `number` in the popup dialog box.

6. Right-click on the `number` node created in the previous step and select `As loop element`.

7. Select the `string` column of the `GetUserNumber` table to the left and drop it onto the Expression field of the `number` node of the `ResponseUserNumber` table to the right.

8. Click OK to save the settings.

### Configuring the tRESTResponse component

#### Procedure

1. Connect `tXMLMap` to a `tRESTResponse` using `Row > ResponseUsers` connection. The schema defined in `tXMLMap` is retrieved in `tRESTResponse` automatically.

2. Select **OK(200)** from the Return status code list.
3. Leave the rest of the settings as they are.
4. Connect **tRESTRequest** to the other **tRESTResponse** using the **Row > GetUserNumber** connection.

**Saving and executing the Job**

**Procedure**

1. Save the Job and press **F6** to execute it.

```
[statistics] connecting to socket on port 3888
[statistics] connected
[INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8088/user
[INFO ]: org.eclipse.jetty.server.AbstractConnector - Started SelectChannelConnector@localhost:8088
```

2. Go to your browser if you want to test the service.

![Firefox](http://localhost:8088/users/1)

This XML file does not appear to have any style information associated with it. The document tree is shown below.

```
<root>
  <foo>1</foo>
</root>
```

![Firefox](http://localhost:8088/users/foo)

This XML file does not appear to have any style information associated with it. The document tree is shown below.

```
<root>
  <foo>foo</foo>
</root>
```

The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

3. Repeat this step and type in **http://localhost:8088/user/number?string=123** in the address bar. Press Enter.

You can see that **123** is returned in the response.
Using URI Query parameters to explore the data of a database

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to use URI query parameters in tRESTRequest to explore data of a database, and send the response via the tRESTResponse.

To do so, you can create two subjobs linked together by an OnSubjobOk connection; this way the two subjobs will be executed sequentially. For more information on Trigger connection, see the Talend Studio User Guide. The first subjob will create and populate the database and the second one will allow to explore the database through the REST service.

Creating the first subJob

About this task

To do this, proceed as follows:

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput from the Misc family and tMysqlOutput from the Databases > Mysql family.
2. Link tFixedFlowInput to tMysqlOutput using a Row > Main connection.
3. Double-click **tFixedFlowInput** to display its **Basic settings** view:

![tFixedFlowInput Basic settings](image)

4. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor](image)

5. In the schema editor, click the [+] button three times to add three lines and set them as displayed in the above screenshot.

6. Click **Ok**.

7. Back to **tFixedFlowInput Basic settings** view, in the **Mode** area, select the **Use inline table** option.

8. Under the inline table, click the [+] button three times to add three rows in the table.

9. In the inline table, click the id field of the first row and type in 1.

10. Click the firstname field of the first row, press **Ctrl+Space** to display the autocompletion list and select the **TalendDataGenerator.getFirstName()** variable in the list.

11. Click the lastname field of the first row, press **Ctrl+Space** to display the autocompletion list and select the **TalendDataGenerator.getLastName()** variable in the list.

12. Do the same for the two following rows to obtain the settings displayed in the screenshot.
13. Double-click tMysqlOutput to display its **Basic settings** view:

14. From the **Property Type** list, leave **Built-in** and fill in the **Host**, **Port**, **Database**, **Username** and **Password** fields manually. If you centralized your connection information to the database in the **Metadata > DB Connections** node of the **Repository**, you can select **Repository** from the list and the fields will be automatically filled in.

For more information about storing metadata, see *Talend Studio User Guide*.

15. In the **Table** field, type in the name of the table in which the data will be loaded, for example: **users**.

16. From the **Action on table** list, select **Drop table if exists and create**, select **Insert** from the **Action on data** list.

17. Click **Sync columns** to retrieve the schema coming from the previous component.

**Creating the second subJob**

The following components are used as displayed in the first screenshot:

- **tRESTRequest** and **tRESTResponse** from the **ESB > REST** family,
- **tFlowToIterate** from the **Orchestration** family,
- **tMysqlInput** from the **Databases > Mysql** family,
- **tXMLMap** from the **Processing** family.

**Configuring the tRESTRequest component**

**About this task**

To do this, proceed as follows:
Procedure

1. Double-click **tRESTRequest** in the design workspace to display its **Basic settings** view:

![tRESTRequest with Basic settings](image)

2. Fill the **REST Endpoint** field with the URI location where the REST-ful web service will be accessible for requests. For example, "http://localhost:8088/users".

3. Click the [+] button to add one line in the **REST API Mapping** table.

4. Select the newly-added line and click the [...] button in the **Output Flow** column to add a schema for the output flow.

5. In the dialog box, name the output flow **getUsers**. A schema editor dialog box appears.

![Schema editor dialog box](image)

6. In the schema editor, click the [+] button twice to add two lines and set them as displayed in the above screenshot.

7. Click **OK**.

8. Back to **tRESTRequest Basic settings** view, select **GET** from the list in the **HTTP Verb** column.

9. Leave the **URI Pattern** column as is.

10. Use the corresponding link to connect to the following component: connect **tRESTRequest** to **tFlowToIterate** using **Row > getUsers** connection.
11. Leave the tFlowToIterate settings as is.
12. Connect tFlowToIterate to tMysqlInput using Row > Iterate connection.

**Configuring the tMysqlInput component**

**About this task**

To do this, proceed as follows:

**Procedure**

1. Double-click tMysqlInput to display its **Basic settings** view:

![Image of tMysqlInput settings]

2. From the **Property Type** list, leave **Built-in** and fill in the **Host**, **Port**, **Database**, **Username** and **Password** fields manually. If you centralized your connection information to the database in the **Metadata > DB Connections** node of the **Repository**, you can select **Repository** from the list and the fields will be automatically filled in.

   For more information about storing metadata, see *Talend Studio User Guide*.

3. Leave the **Schema** list as **Built-in** and click the [... ] button next to the **Edit schema** field.

4. In the schema editor, define the schema exactly like the one of the tFixedFlowInput.

5. In the **Table Name** field, fill in the name of the table in which the data are stored: **users**.

6. Leave the **Query Type** list as **Built-in** and fill in the **Query** field with the following SQL query allowing to explore the database data with the URI query set in the tRESTRequest component:

   ```
   "select * from users where id >= " + globalMap.get("getUsers.from") + " and id <= " + globalMap.get("getUsers.to")
   ```

**Configuring the tXMLMap component**

**Procedure**

1. Right-click tMysqlInput, hold and drag to tXMLMap to connect the two components together.
2. Double-click `tXMLMap` in the design workspace to open the **Map Editor**.

3. Click the `+` button on the top right to add an output and name it as `ResponseUsers`.

4. Click the `+` button on the bottom right to add two columns for the output.
   - Name the first column as `body` and set the **Type** to **Document**.
   - Name the second column as `string` and set the **Type** to **String**.

5. Right-click on the `root` node, select **Rename** in the list and rename it `users`.

6. Right-click on the `users` node and select **Create Sub-Element** to create a sub-element. Name the sub-element `user` in the popup dialog box.

7. Right-click on the `user` node created in the previous step and select **As loop element**.

8. Select the `id` column of the `row2` table to the left and drop it onto the `user` node of the `ResponseUsers` table to the right.

9. In the **Selection** dialog box, select the **Create as attribute of target** node option and click **OK**.

10. Select the `firstname` and `lastname` columns of the `row2` table to the left and drop it onto the `user` node of the `ResponseUsers` table to the right.
11. In the Selection dialog box, select the Create as sub-element of target node option and click OK.
12. Click the wrench icon on the top of the ResponseUsers table to open the setting panel.

13. Set the All in one feature as true, this way all XML data is outputted in one single flow.
14. Click OK to save the settings.

Configuring the tRESTResponse component

Procedure
1. Connect tXMLMap to tRESTResponse using Row > ResponseUsers connection.
2. The schema defined in tXMLMap is retrieved in tRESTResponse automatically. Leave the other settings as they are.
Connecting the two subJobs

About this task

Now that the two subJobs are created, you can connect them together:

Procedure

1. Right-click the \texttt{tFixedFlowInput} component of the first subjob.
2. Select \texttt{Trigger > OnSubjobOk} on the list.
3. Click the \texttt{tRESTRequest} component of the second subJob.

Results

This way, when executing the job, the second subJob will be executed only if the first one’s execution succeeded.

Saving and executing the Job

Procedure

1. Save the Job and press \texttt{F6} to execute it.

   ```
   [statistics] connecting to socket on port 4020
   [statistics] connected
   [INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8080/users
   [INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
   SelectChannelConnector@localhost:8088
   ```

2. Go to your browser if you want to test the service.

   For example, use the URI query \texttt{?to=2} to retrieve the data of the two first users.
The HTTP request for a user id is accepted by the REST service and the HTTP response is sent back to the server.

For a use case that calls this REST service using Talend Open Studio for ESB components, see Getting user information by interacting with a RESTful service on page 3050.

Using a REST service to accept HTTP POST requests

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes a Job composed of two subjobs: the first subjob exposes a REST service that accepts HTTP POST requests from REST clients, writes data to a database upon receiving an HTTP request, and displays the server-client exchange information on the Run console; the second subjob displays the results of database updates.
Setting up the Job

Procedure

1. Create a Job and add the following components to the Job by typing their names in the design workspace or dropping them from the Palette: a tRESTRequest, a tMysqlOutput, a tXMLMap, and a tRESTResponse.
2. Connect the tRESTRequest to the tMysqlOutput component using a Row > Main connection, and give the output flow a name, request in this example.
3. Connect the tMysqlOutput component to the tXMLMap component using a Row > Main connection.
4. Connect the tXMLMap component to the tRESTResponse component using a Row > Main connection, and give it a name, response in this example. Click OK in the pop-up dialog box to accept the schema propagation from the tRESTResponse component.
5. Add a tMysqlInput component and a tLogRow component to the Job by typing their names in the design workspace or dropping them from the Palette, and connect the tMysqlInput to the tLogRow using a Row > Main connection.
6. Connect the tMysqlOutput to the tMysqlInput using a Trigger > OnComponentOk connection to link the two subjobs.

Configuring the components

Configuring REST request parameters

Procedure

1. Double-click the tRESTRequest component to open its Basic settings view.

2. Fill the REST Endpoint field with the URI location where the REST service will be accessible for requests, "http://localhost:8045/users" in this example.
3. Click the output flow name, which is request in this example, in the Output Flow column of the REST API Mapping table to show the [...] button, and click the button to open the Schema dialog box. Then define the schema for the request flow as follows:
   • id, type Integer, 2 characters long, set as the key column
   • first_name, type String
   • last_name, type String
When done, click **OK** to validate the schema setting and close the dialog box.

4. Click the **HTTP Verb** column and select **POST** from the list.

5. In the **URI Pattern** column, enter the acceptable URI pattern of POST requests, "/post/{id}/
   {first_name}/{last_name}" in this example.
   Leave the rest parameters as they are.

6. Click the **Advanced settings** tab, and select the **Log messages** check box.

Configuring the database and the response parameters

**Procedure**

1. Double-click the **tMysqlOutput** component to open its **Basic settings** view.

2. Leave the **Property Type** as **Built-in** and fill in the database connection details manually in the **Host**, **Port**, **Database**, **Username** and **Password** fields.
   If you have centralized your connection information to the database in the **Metadata > DB Connections** node of the **Repository**, you can select **Repository** from the **Property Type** list and browse to the centralized connection to have the fields automatically filled in. For more information about storing metadata, see *Talend Studio User Guide*.
3. Fill in the **Table** field with the target database table name, *users* in this example.

4. Select the actions to be carried out on the database table and data according to your needs from the corresponding lists. In this example, the target table will be created if it does not exist in the specified database, and data from client requests will be inserted, or updated if it already exists, to the database table.

5. Click the **Sync columns** button to synchronize the table schema with the input schema.

6. Double-click the **tXMLMap** component to open the Map Editor.

7. Rename the root node in the output table: right-click the node, select **Rename** from the contextual menu, and specify a new name in the pop-up dialog box, *user* in this example.

8. Select all the three columns in the input table and drop them onto the *user* node, and select the **Create as sub-element of target node** option from the pop-up dialog box to set these columns as sub-elements of the *user* node. When done, click **OK** to validate the mappings and close the Map Editor.

9. Double-click the **tRESTResponse** component and set the response parameters according to your needs. In this example, we keep the default settings for all the parameters.

**Configuring result display**

**Procedure**

1. Double-click the **tMysqlInput** component to open its **Basic settings** view.
2. Specify the database connection details, table name and table schema, which are the same as in the `tMysqlOutput` component.

3. Click the **Guess Query** button to fill the **Query** field with the query statement.

4. Double-click the `tLogRow` component and select the **Table** option to display the content of the database in table cells.

### Saving the executing the Job

#### Procedure

1. Press **Ctrl+S** to save your Job.

2. Click the **Run** button on the **Run** tab or press **F6** to run it.

   The console displays the service implementation information, including the service URL.

   ```plaintext
   [statistics] connecting to socket on port 3306
   [statistics] connected
   [INFO ]: org.apache.cxf.endpoint.ServerImpl - Setting the server's publish address to be http://localhost:8045/users
   [INFO ]: org.eclipse.jetty.server.AbstractConnector - Started
   SelectChannelConnector@localhost:8045
   ```

   When an HTTP POST request is received from a client, the console displays the relevant exchange information and the database update result.
For a use case that calls this REST service using the HTTP POST method, see Updating user information by interacting with a RESTful service on page 3056.

Using a REST service to accept HTTP POST requests and send responses

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to build a REST service that accepts HTTP POST requests of Document type from the client, processes it and sends the response back. To do this, two Jobs are built: one to create the REST service and the other to call it.

Creating the REST service Job

Drag and drop the following components from the Palette onto the design workspace: a tRESTRequest, a tXMLMap and a tRESTResponse.
Configuring the tRESTRequest component

**Procedure**

1. Double-click **tRESTRequest** in the design workspace to display its **Basic settings** view.

2. In the **REST Endpoint** field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+] button to add one line in the **REST API Mapping** table.

4. Select the newly-added line and click the [...] button in the **Output Flow** column to add a schema for the output flow. Give the name for the schema **UserInfo** in this scenario.

The schema editor opens. Click the [+] button to add a new line **body of Document** type and click **OK** to save the schema.
5. Back to tRESTRequest Basic settings view, select POST from the list in the HTTP Verb column.
6. Fill the field in the URI Pattern column with "/UserInfo". Keep the default settings of the other options.

Configuring the body of the response

Procedure
1. Connect tRESTRequest to tXMLMap using the Row > UserInfo connection.
2. Double-click tXMLMap in the design workspace to open the Map Editor.
3. Right-click on the root node of the input table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

4. Right-click on the person node created in the previous step and select As loop element.

5. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id and name in this use case.

6. Click the [+][button on the top right to add an output and name it as Response.

7. Click the [+][button on the bottom right to add a column body of Document type for the output.

8. Right-click the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

9. Right-click the person node created in the previous step and select As loop element.

10. Create three sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, name and company in this use case.

11. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

12. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.

   Click the Expression field of the name node in the output table, and click [...] in this field to show the Expression Builder wizard.

   In the Expression area, enter StringHandling.UPCASE([UserInfo.body:/root/person/name]) to convert the name of the user to upper case. Click OK to close the wizard.

13. In the Expression field of the company node, enter “Talend”.

14. Click OK to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect tXMLMap to a tRESTResponse using Row > Response connection.
   
   The schema defined in tXMLMap is retrieved in tRESTResponse automatically.

   For further information about using the Expression Builder, see Talend Studio User Guide.
2. Select **OK(200)** from the **Return status code** list.
3. Leave the rest of the settings as they are.

**Launching the service**

Save the Job and press **F6** to execute it. The service is started.

**Creating the consumer Job**

Drag and drop the following components from the **Palette** onto the design workspace: a **tFixedFlowInput**, a **tXMLMap**, a **tRESTClient** and a **tLogRow**.

**Configuring the tFixedFlowInput component**

**Procedure**

1. Double-click **tFixedFlowInput** in the design workspace to display its **Basic settings** view.
2. Click **Edit schema** to show the schema editor. In the schema editor, click the [+] button to add two columns of **String** type, *id* and *name*. Click **Ok** to close the schema editor.

3. Back to **tFixedFlowInput** Basic settings view, in the **Mode** area, select the **Use Inline Content** option.

4. In the **Content** box, enter the *id* and *name* of three users, for example:

```plaintext
1;ford
2;smith
3;thomson
```

**Configuring the tXMLMap component**

**Procedure**

1. Connect **tFixedFlowInput** to **tXMLMap** using the **Row > Main** connection.
2. Connect **tXMLMap** to **tRESTClient** using the **Row > Main** connection, and name the output flow *request* in this example.
3. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
4. Right-click on the node root in the output table and select Create Sub-Element. Name the sub-element as person in the popup dialog box.

5. Right-click on the person node created in the previous step and select As loop element.

6. Create two sub-elements to the person node by selecting Create Sub-Element in the contextual menu, id, and name in this use case.

7. Select the id column from the input table and drop it onto the Expression field of the id node of the output table.

8. Select the name column from the input table and drop it onto the Expression field of the name node in the output table.

9. Click OK to save the settings.

Configuring the tRESTClient component

Procedure

1. Double-click the tRESTClient component to open its Basic settings view.
2. Fill the **URL** field with the URL of the REST service built in the service Job, "http://localhost:8088/".
3. Fill the **Relative Path** with the "UserInfo".
4. From the **HTTP Method** list, select **POST**.
5. Leave the rest of the settings as they are.
6. Connect **tRESTClient** to **tLogRow** using the **Row > Response** connection. Keep the default settings of the **tLogRow** to monitor the message exchanges.

**Saving and executing the Job**

Save the Job and press **F6** to execute it. The user information is shown in the console, including *id*, *name*, and *company*. The name of the user has been converted to upper case.
Using a REST service to accept HTTP POST requests in an HTML form

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to upload data to a REST service using HTTP POST in a HTML form file. To do so, a Job is created to accept HTTP POST requests using the tRESTRequest component.

A predefined HTML form UploadFile.html is used to upload data to the REST service:

```html
<form action="http://localhost:8088/UserInfo" method="post" enctype="multipart/form-data">
  <input type="file" name="id" />
  <button>upload</button>
</form>
```

The customer.xml that contains a user ID will be uploaded:

```xml
<customer>
  <id>100</id>
</customer>
```

Setting up the Job

Drop the following components from the Palette onto the design workspace: a tRESTRequest, a tJavaRow, a tXMLMap and a tRESTResponse.
Configuring the tRESTRequest component

Procedure

1. Double-click tRESTRequest in the design workspace to display its Basic settings view.

2. In the REST Endpoint field, keep the default URI "http://localhost:8088/" where the REST-ful web service will be accessible for requests.

3. Click the [+] button to add one line in the REST API Mapping table.

4. Select the newly-added line and click the [...] button in the Output Flow column to add a schema for the output flow. Give the name for the schema UserInfo in this scenario.

   The schema editor opens. Click the [+] button to add a new line id of byte[] type and enter multipart in the Comment field. Click OK to save the schema.

5. Back to tRESTRequest Basic settings view, select POST from the list in the HTTP Verb column.

6. Fill the field in the URI Pattern column with "/UserInfo".

7. Select Multipart in the Consumes list. Keep the default settings of the other options.
Configuring the tJavaRow component

Procedure

1. Connect **tRESTRequest** to **tJavaRow** using the **Row > UserInfo** connection.
2. Double-click **tJavaRow** in the design workspace to display its **Basic settings** view.

```
String result = new String(input_row.id, 0, input_row.id.length);
routines.system.Document doc = new routines.system.Document();
doc.setDocument(org.dom4j.DocumentHelper.parseText(result));
output_row.id = doc;
System.out.println(result);
```

Configuring the tXMLMap component

Procedure

1. Connect **tJavaRow** to **tXMLMap** using the **Row > Main** connection.
2. Double-click **tXMLMap** in the design workspace to open the **Map Editor**.
3. Click the [+] button on the bottom left to add a column `id` of `Document` type for the input.

4. Right-click the root node of the input table and select Rename in the contextual menu and rename it `customer`.

5. Create a sub-element to the `customer` node by selecting Create Sub-Element in the contextual menu. Name the sub-element as `id` in the pop-up dialog box.

6. Click the [+] button on the top right to add an output and name it as `response`.

7. Click the [+] button on the bottom right to add a column `body` of `Document` type for the output.

8. Right-click the root node of the input table and select Rename in the contextual menu and rename it `customer`.

9. Create a sub-element to the `customer` node by selecting Create Sub-Element in the contextual menu. Name the sub-element as `id` in the pop-up dialog box.

10. Select the `id` column from the input table and drop it onto the Expression field of the `id` node of the output table.

11. Click OK to save the settings.

**Configuring the tRESTResponse component**

**Procedure**

1. Connect tXMLMap to a tRESTResponse using Row > response connection. The schema defined in tXMLMap is retrieved in tRESTResponse automatically.
2. Select **OK(200)** from the Return status code list.

3. Leave the rest of the settings as they are.

**Saving and executing the Job**

**Procedure**

1. Save the Job and press **F6** to execute it.

2. Run the *UploadFile.html* using a web browser.

3. Click the **Browse** button to navigate to the *customer.xml* that contains the user ID and click **upload**.
4. The HTTP POST request is accepted by the REST service and the user ID is sent back to the server.

You can also view the response in the page source.

5. The content of the input file is printed in the execution console.
[statistics] connecting to socket on port 3805

  <id>100</id>
</customer>
tRESTResponse

Returns a specific HTTP status code to the client end as a response to the HTTP and/or HTTP requests.

Note:
To enable the HTTPS support, you have to generate a keystore and add some HTTPS security configuration properties in the org.ops4j.pax.web.cfg file of your Runtime container. For more information, see the Talend ESB Container Administration Guide.

tRESTResponse Standard properties

These properties are used to configure tRESTResponse running in the Standard Job framework.

The Standard tRESTResponse component belongs to the ESB family.

This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).

Basic settings

<table>
<thead>
<tr>
<th>Return Body Type</th>
<th>Select a response body type from Document, String, and Byte in the list.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Return status code</td>
<td>Select a status code from the list to indicate the request status.</td>
</tr>
<tr>
<td></td>
<td>- &lt;&lt;Custom&gt;&gt;: This option allows you to customize the status code. Enter the status code of your choice in the field.</td>
</tr>
<tr>
<td></td>
<td>- Bad Request (400): The request had bad syntax or was inherently impossible to be satisfied.</td>
</tr>
<tr>
<td></td>
<td>- Internal Server Error (500): The server encountered an unexpected condition which prevented it from fulfilling the request.</td>
</tr>
<tr>
<td></td>
<td>- OK (200): The request was fulfilled.</td>
</tr>
<tr>
<td></td>
<td>- Resource Not Found (404): The server has not found anything matching the URI given.</td>
</tr>
<tr>
<td>Schema and Edit schema</td>
<td>A schema is a row description, that is, it defines the number of fields to be processed and passed on to the next component.</td>
</tr>
<tr>
<td></td>
<td>The schema mode is Built-in: it is created and stored locally for this component.</td>
</tr>
<tr>
<td></td>
<td>Click Edit schema to make changes to the schema.</td>
</tr>
<tr>
<td></td>
<td>The input flow is retrieved from the previous component connected to tRESTResponse. Any change of the input flow in tRESTResponse will also be propagated to the previous component automatically.</td>
</tr>
<tr>
<td></td>
<td>The output flow of tRESTResponse is a hard-coded field named body, the type of which is defined in the Return Body Type list.</td>
</tr>
</tbody>
</table>
**Advanced settings**

<tr>
<td>This component covers the possibility that a Talend Job can be wrapped as a service, with the ability to input a request to a service into a Job and return the Job result as a service response.</td>
<td></td>
</tr>
<tr>
<td>The <strong>tRESTResponse</strong> component should only be used with the <strong>tRESTRequest</strong> component to provide a Job result as response for a web service provider, in case of a request-response communication style.</td>
<td></td>
</tr>
</tbody>
</table>

**Related scenario**

For a scenario in which **tRESTResponse** is used, see [Using a REST service to accept HTTP GET requests and send responses](#) on page 3066.
tRiakBucketList

Retrieves a list of buckets from a Riak cluster and iterates on it.

**tRiakBucketList Standard properties**

These properties are used to configure tRiakBucketList running in the Standard Job framework.

The Standard tRiakBucketList component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes</td>
<td>Fill in the information required for a connection to a Riak cluster. • Host: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to. • Port: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098. • Riak path: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak. One example of the URL for accessing a Riak node is <a href="http://127.0.0.1:8098/riak">http://127.0.0.1:8098/riak</a>. For more information about the concepts related to Riak, see <a href="https://docs.basho.com/riak/kv/2.2.0/learn/concepts/">https://docs.basho.com/riak/kv/2.2.0/learn/concepts/</a>.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>CURRENT_BUCKET_NAME</strong>: the current bucket name. This is a Flow variable and it returns a string. <strong>NB_LINE</strong>: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. <strong>ERROR_MESSAGE</strong>: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
</table>
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see *Talend Studio User Guide*.

### Usage

| Usage rule | This component can be used as a standalone component. |

### Related scenarios

No scenario is available for the Standard version of this component yet.
tRiakClose

Closes an active connection to a Riak cluster so as to release occupied resources.

**tRiakClose Standard properties**

These properties are used to configure tRiakClose running in the Standard Job framework.

The Standard tRiakClose component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

### Basic settings

| Component List | Select an active connection to a Riak cluster to be closed. |

### Advanced settings

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component is generally used with other Riak components, particularly tRiakConnection. |

**Related Scenario**

For a scenario in which tRiakClose is used, see Exporting data from a Riak bucket to a local file on page 3108.
tRiakConnection

Opens and reuses of the connection it creates to a Riak cluster.

tRiakConnection Standard properties

These properties are used to configure tRiakConnection running in the Standard Job framework.

The Standard tRiakConnection component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Nodes</th>
<th>Fill in the information required for a connection to a Riak cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• Host: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.</td>
<td></td>
</tr>
<tr>
<td>• Port: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.</td>
<td></td>
</tr>
<tr>
<td>• Riak path: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.</td>
<td></td>
</tr>
</tbody>
</table>

One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak.

For more information about the concepts related to Riak, see [https://docs.basho.com/riak/kv/2.2.0/learn/concepts/](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

**Global Variables**

| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. | |
| A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. | |
| To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. | |

For further information about variables, see [Talend Studio User Guide](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).
Usage

| Usage rule | This component is generally used with other Riak components, particularly tRiakClose. |

Related scenario

For a scenario in which tRiakConnection is used, see Exporting data from a Riak bucket to a local file on page 3108.
tRiakInput

Extracts the desired data from a bucket in a Riak node so as to store or apply changes to the data. tRiakInput reads data from a Riak bucket and send data in the Talend flow.

tRiakInput Standard properties

These properties are used to configure tRiakInput running in the Standard Job framework. The Standard tRiakInput component belongs to the Big Data and the Databases NoSQL families. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Schema and Edit Schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>• View schema: choose this option to view the schema only.</td>
</tr>
<tr>
<td></td>
<td>• Change to built-in property: choose this option to change the schema to Built-in for local changes.</td>
</tr>
<tr>
<td></td>
<td>• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.</td>
</tr>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</td>
</tr>
<tr>
<td>Nodes</td>
<td>Fill in the information required for a connection to a Riak cluster.</td>
</tr>
<tr>
<td></td>
<td>• Host: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.</td>
</tr>
<tr>
<td></td>
<td>• Port: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.</td>
</tr>
<tr>
<td></td>
<td>• Riak path: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.</td>
</tr>
<tr>
<td></td>
<td>One example of the URL for accessing a Riak node is <a href="http://127.0.0.1:8098/riak">http://127.0.0.1:8098/riak</a>.</td>
</tr>
</tbody>
</table>
For more information about the concepts related to Riak, see https://docs.basho.com/riak/kv/2.2.0/learn/concepts/.

<table>
<thead>
<tr>
<th>Bucket</th>
<th>Type in the name of the bucket from which you want to read data.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>Type in the key which is associated with the data that you want to read.</td>
</tr>
<tr>
<td>Output key to column</td>
<td>Select this check box and from the list select the desired column to which the keys will be output.</td>
</tr>
<tr>
<td>Values column</td>
<td>Customize the columns to which the values will be output.</td>
</tr>
</tbody>
</table>

### Advanced settings

| tStatCatcher Statistics     | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

| Global Variables | NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer. |
|------------------| ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. |
|                  | A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
|                  | To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. |
|                  | For further information about variables, see Talend Studio User Guide. |

### Usage

| Usage rule | This component always needs an output link. |

### Exporting data from a Riak bucket to a local file

This scenario applies only to Talend products with Big Data.

The following scenario describes a Job which reads data from a Riak bucket and writes it into a local txt file.
Prerequisites: The Riak bucket from which you want to export data already exists. In this example, the data from the bucket `computer` will be exported and the bucket has already imported the following data:

<table>
<thead>
<tr>
<th>id</th>
<th>company</th>
<th>brand</th>
<th>price</th>
<th>owner</th>
</tr>
</thead>
<tbody>
<tr>
<td>001</td>
<td>Dell</td>
<td>Inspiron 15</td>
<td>299</td>
<td>Amanda</td>
</tr>
<tr>
<td>002</td>
<td>Dell</td>
<td>Inspiron 15R</td>
<td>549</td>
<td>Linda</td>
</tr>
<tr>
<td>003</td>
<td>HP</td>
<td>Pavilion 500-210qe</td>
<td>539</td>
<td>Marina</td>
</tr>
<tr>
<td>004</td>
<td>HP</td>
<td>Pavilion 500-075</td>
<td>599</td>
<td>Diana</td>
</tr>
</tbody>
</table>

Dropping and linking components

Procedure

1. Drop the following components from the Palette to the design workspace: `tRiakConnection`, `tRiakInput`, `tFileOutputDelimited`, and `tRiakClose`.
2. Connect `tRiakConnection` to `tRiakInput` using a Trigger > On Subjob Ok link.
3. Connect `tRiakInput` to `tFileOutputDelimited` using a Row > Main link.
4. Connect `tFileOutputDelimited` to `tRiakClose` using a Trigger > On Component Ok link.

Configuring the components

Opening a connection to Riak

Procedure

1. Double-click `tRiakConnection` to open its Basic settings view in the Component tab.

2. In the Nodes table, enter the information of a Riak cluster you want to connect to.
Exporting data from a Riak bucket to a local file

Procedure

1. Double-click tRiakInput to open its Basic settings view in the Component tab.

2. Click Edit schema to define the structure of exported data. In this example, three columns are defined: id, company, and price.

3. Select the Use an existing connection check box and then select the connection you have configured earlier. In this example, it is tRiakConnection_1.

4. In the Bucket field, enter the name of the bucket from which the data will be exported, computer in this example.
5. Select the **Output key to column** check box, and select the desired column from the list. *id* is selected in this example.

6. In the **Value columns** table, click twice the **button and select *company* and *price* from the list respectively.

**Writing data into a local file**

**Procedure**

1. Double-click **tFileOutputDelimited** to open its **Basic settings** view in the **Component** tab.

   ![tFileOutputDelimited]  
   ![Basic settings](#)

   - In the **File Name** field, enter the full path to the local file in which you want to store the exported data, *D:/Output/computer.txt* in this example.
   - Select the **Include Header** check box.
   - Leave other settings as they are.

2. **Closing the connection to Riak**

   **Procedure**

   1. Double-click **tRiakClose** to open its **Basic settings** view in the **Component** tab.

   ![tRiakClose]  
   ![Basic settings](#)

   2. Select the connection you want to close from the **Component List**, **tRiakConnection_1** in this example.

3. **Saving and executing the Job**

   **Procedure**

   1. Press **Ctrl+S** to save your Job.
   2. Execute the Job by pressing **F6** or clicking **Run** on the **Run** tab.
   3. Go to the local directory where the file is stored and check the exported data from the Riak bucket.
<table>
<thead>
<tr>
<th>id</th>
<th>company</th>
<th>price</th>
</tr>
</thead>
<tbody>
<tr>
<td>003</td>
<td>HP</td>
<td>539</td>
</tr>
<tr>
<td>004</td>
<td>HP</td>
<td>599</td>
</tr>
<tr>
<td>001</td>
<td>Dell</td>
<td>299</td>
</tr>
<tr>
<td>002</td>
<td>Dell</td>
<td>549</td>
</tr>
</tbody>
</table>
tRiakKeyList

Retrieves a list of keys and iterates on it within a Riak bucket for analysis or development purposes.

**tRiakKeyList Standard properties**

These properties are used to configure tRiakKeyList running in the Standard Job framework.

The Standard tRiakKeyList component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Nodes</td>
<td>Fill in the information required for a connection to a Riak cluster.</td>
</tr>
<tr>
<td>Host</td>
<td>enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.</td>
</tr>
<tr>
<td>Port</td>
<td>enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.</td>
</tr>
<tr>
<td>Riak path</td>
<td>enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.</td>
</tr>
<tr>
<td>Bucket</td>
<td>Type in the name of the bucket from which you want to retrieve all keys.</td>
</tr>
</tbody>
</table>

One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak.

For more information about the concepts related to Riak, see https://docs.basho.com/riak/kv/2.2.0/learn/concepts/.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>CURRENT_KEY: the current key. This is a Flow variable and it returns a string.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable.</td>
</tr>
</tbody>
</table>
and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component can be used as a standalone component. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tRiakOutput

Receives data from the preceding component and writes data into or deletes data from a bucket in a Riak cluster.

tRiakOutput Standard properties

These properties are used to configure tRiakOutput running in the Standard Job framework.

The Standard tRiakOutput component belongs to the Big Data and the Databases NoSQL families.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Basic settings

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
• View schema: choose this option to view the schema only.  
• Change to built-in property: choose this option to change the schema to Built-in for local changes.  
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In: You create and store the schema locally for this component only.</td>
<td></td>
</tr>
<tr>
<td>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually. You can find more details about how to verify default values in retrieved schema in Talend Help Center (<a href="https://help.talend.com">https://help.talend.com</a>).</td>
<td></td>
</tr>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined. If you select the Use an existing connection check box, the Nodes table will not be available.</td>
</tr>
</tbody>
</table>
Fill in the information required for a connection to a Riak cluster.

- **Host**: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.
- **Port**: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.
- **Riak path**: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.

One example of the URL for accessing a Riak node is http://127.0.0.1:8098/riak.

For more information about the concepts related to Riak, see [https://docs.basho.com/riak/kv/2.2.0/learn/concepts/](https://docs.basho.com/riak/kv/2.2.0/learn/concepts/).

### Nodes

<table>
<thead>
<tr>
<th>Fill in the information required for a connection to a Riak cluster.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Host</strong>: enter the IP address or hostname of a Riak node in the Riak cluster that you want to connect to.</td>
</tr>
<tr>
<td><strong>Port</strong>: enter the listening port number of a Riak node. You can leave this field empty to use its default value 8098.</td>
</tr>
<tr>
<td><strong>Riak path</strong>: enter the Riak path for accessing a Riak node. You can leave this field empty to use its default value riak.</td>
</tr>
</tbody>
</table>

### Bucket

**Specify the name of the bucket to which you want to apply changes.**

### Action on data

**In the specified bucket, you can perform:**

- **Upsert**: Insert data if they do not exist or update the existing data.
- **Delete**: Remove values associated with the specified key.

If you select **Delete** from the **Action on data** list, only the **Key column** list is available in the **Key area**.

### Auto generate the key

**Select this check box to let the Riak system generate keys for the values automatically.**

### Key column

**Select one column from the list to write its data into the Riak bucket as keys. Note that the key must be unique across one bucket.**

### Value columns

**Customize the columns to write their data into the Riak bucket as values.**

### Advanced settings

**tStatCatcher Statistics**

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**Global Variables**

- **UPSERT_NB_LINE**: the number of rows inserted and updated. This is an After variable and it returns an integer.
- **DELETE_NB_LINE**: the number of rows deleted. This is an After variable and it returns an integer.
- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule                                                                 | This component is used as an output component and it always needs an incoming link. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tRouteFault

Sends messages from a Data Integration Job to a Mediation Route and mark the message as fault.

tRouteFault Standard properties

These properties are used to configure tRouteFault running in the Standard Job framework.

The Standard tRouteFault component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

Basic settings

<table>
<thead>
<tr>
<th>Output Schema and Edit schema</th>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see *Talend Studio User Guide*. |

**Usage**

| Usage rule | This component can be used as the end component and thus requires an input component. |
| Limitation | The Job using a **tRouteFault** must be launched only within a Route using the **cTalendJob** component. |

**Exchanging messages between a Job and a Route**

This scenario applies only to *Talend Open Studio for ESB*, *Talend Data Services Platform* and *Talend Data Fabric*.

This scenario describes how to exchange messages between a Job and a Route using the **tRouteInput** and the **tRouteFault** component. To do this, a Job is created to receive the message from the Route and mark the message as fault. Then a Route is built to send the message to the Job and handle the fault message.

**Creating an Data Integration Job**

In this section, a Job named *RouteCommunication_tRouteFault* is built.
Arranging the flow of the message

About this task

Procedure
1. Drag and drop a **tRouteInput** and a **tRouteFault** from the **Palette** onto the design workspace.
2. Right-click the **tRouteInput** component, select **Row > Main** from the contextual menu and click the **tRouteFault** component.

Configuring how the message is processed

Procedure
1. Double-click the **tRouteInput** component to open its **Basic settings** view in the **Component** tab.

2. Click the three-dot button next to **Edit Schema**. In the schema dialog box, click the plus button to add a new line of **String** type and name it **body**. Click **OK** to close the dialog box.
3. In the **Simple Expression** field for the `body` element, enter "${in.body}" to get the body of the input message from the Route.

4. Double-click the `tRouteFault` component to display its **Basic settings** view in the **Component** tab.

5. Make sure that `tRouteFault` has one element `body`. Set its type to **Body**.

6. Press **Ctrl+S** to save your Job.

### Creating a Mediation Route

In this section, we will create a Route to send a message to the Job and handle the fault message.

#### Dropping and linking the components

About this task

![Diagram of components](image)

Procedure

1. Drag and drop a `cTimer`, a `cSetBody`, a `cJavaDSLProcessor`, a `cTalendJob`, a `cOnException` and a `cProcessor` component from the **Palette** onto the design workspace.

2. Link the components with the **Row > Route** connection as shown above.

3. Label the components for better identification of their roles.

#### Configuring the components

Procedure

1. Double-click the `cTimer` component to open its **Basic settings** view in the **Component** tab.
2. Enter 1 in the **Repeat** field to trigger a message exchange one time.
3. Double-click the **cSetBody** component to display its **Basic settings** view in the **Component** tab.

4. Select **Simple** from the **Language** list and enter *Hello!* in the **Expression** field.
5. Double-click the **cJavaDSLProcessor** component to open its **Basic settings** view in the **Component** tab.

6. Enter `.handleFault()` in the **Code** box so that the fault message will be caught as an exception.
7. Double-click the **cTalendJob** component to display its **Basic settings** view in the **Component** tab.
8. Select Job `RouteCommunication_tRouteFault` from the repository to call the Job that is created in the previous section.

9. Double click the `cOnException` component to display its Basic settings view in the Component tab.

10. Click `[+]` to add a line to the Exceptions table, and enter `org.apache.camel.CamelException` in the Exception field to handle the exceptions.

11. Double-click the `cProcessor` component to display its Basic settings view in the Component tab.
12. Customize the code in the Code area to show the message body:

```
System.out.println(exchange.getIn());
```

13. Press Ctrl+S to save your Route.

**Executing the Route**

Click the Run view to display it and click the Run button to launch the execution of your Route. You can also press F6 to execute it.

The message *Hello!* is sent from the Route to the Job and caught as exception:
Execution

[statistics] connecting to socket on port 3763
[statistics] connected

    Processed by failure processor:
    FallbackErrorHandler[Channel[DelegateSync[local_project.troutefault_0_1.tRouteFault@102511045b]]]

tRouteInput

Accepts messages in a Data Integration Job from a Mediation Route.

**tRouteInput Standard properties**

These properties are used to configure tRouteInput running in the Standard Job framework.

The Standard tRouteInput component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

| Input Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
| - View schema: choose this option to view the schema only.
| - Change to built-in property: choose this option to change the schema to Built-in for local changes.
| - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
| Built-in: No property data stored centrally. |
| Repository: Select the Repository file where Properties are stored. |
| Camel | Enter the message parameters corresponding to the columns you defined in the schema dialog box via the Edit schema button using the Simple Expression Language. For more information about the Simple Expression Language, see the site http://camel.apache.org/simple.html. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable |
and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component can be used as starter component and has an output. It is mandatory that a tRouteInput component is used in the Data Integration Job to be called by a Route using the cTalendJob component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Limitation</td>
<td>The Job using a tRouteInput must be launched only within a Route using the cTalendJob component.</td>
</tr>
</tbody>
</table>

### Exchanging messages between a Job and a Route

This scenario applies only to Talend Open Studio for ESB, Talend Data Services Platform and Talend Data Fabric.

This scenario describes how to accept messages from a Route using the tRouteInput component and send messages to a Route using the tRouteOutput component. To do this, we need to build a Job and a Route to call the Job using the cTalendJob component.

For more information about how to use the cTalendJob component, see cTalendJob.

### Creating an Data Integration Job

In this section, we will build a Job named RouteCommunication to accept the message from a Route, change the message body and send the message back to the Route.

#### Arranging the flow of the message

About this task
**Procedure**

1. Drag and drop a `tRouteInput`, a `tLogRow`, a `tReplace` and a `tRouteOutput` from the Palette onto the design workspace.
2. Link the components using the Row > Main connection as shown above.

**Configuring how the message is processed**

**Procedure**

1. Double-click the `tRouteInput` component to open its Basic settings view in the Component tab.

2. Click the three-dot button next to Edit Schema. In the schema dialog box, click the plus button to add a new line of String type and name it `body`. Click OK to close the dialog box.

3. In the Simple Expression field for the `body` element, enter "${in.body}" to get the body of the input message from the Route.

4. The `tLogRow` component will monitor the message exchanges and does not need any configuration.

5. Double-click the `tReplace` component to open its Basic settings view in the Component tab.
6. Click **Sync columns** to retrieve the schema from the **tLogRow**. In the pop-up dialog box, click **Yes** to propagate the schema to the subsequent component.

   Click [+] to add a row to the **Search/Replace** table. Enter **World** in the **Search** column and **Talend** in the **Replace with** column. Clear the **Whole word** check box.

7. Double-click the **tRouteOutput** component to display its **Basic settings** view in the **Component** tab.

8. Make sure that **tRouteOutput** has one element **body**. Set its type to **Body**.

9. Press **Ctrl+S** to save your Job.

### Creating a Mediation Route

In this section, we will create a Route to send a message to the Job and receive the message sent back to the Route.
Dropping and linking the components

About this task

![Diagram showing component layout]

**Procedure**

1. Drag and drop a cTimer, a cSetBody, a cTalendJob, and a cLog from the Palette onto the design workspace.
2. Link the components with the Row > Route connection as shown above.
3. Label the components for better identification of their roles.

Configuring the components

**Procedure**

1. Double-click the cTimer component to open its Basic settings view in the Component tab.
   
   ![Basic settings view]
   
   1. In the Repeat field, enter 1 to generate the message exchange one time. Keep the default settings of the other options.

2. Double click the cSetBody component to display its Basic settings view in the Component tab.
   
   ![Basic settings view]
   
   4. Select Simple from the Language list and enter Hello World! in the Expression field.

3. Double-click the cTalendJob component to display its Basic settings view in the Component tab.
6. Select Job *RouteCommunication* from the repository.
7. The **cLog** component will monitor the message exchanges and does not need any configuration.
8. Press **Ctrl+S** to save your Route.

**Executing the Route**

Click the **Run** view to display it and click the **Run** button to launch the execution of your Route. You can also press **F6** to execute it. In the execution log you can see that the message *Hello World!* is sent to the Job. The message body is changed to *Hello Talend!* and sent back to the Route.

```text

[statistics] connecting to socket on port 3989
[statistics] connected
Hello World!
[WARN ]: test_route.cLog_1 - Exchange[ExchangePattern: InOnly, BodyType: String, Body: Hello Talend!]
```
tRouteOutput

Sends messages from a Data Integration Job to a Mediation Route.

**tRouteOutput Standard properties**

These properties are used to configure tRouteOutput running in the Standard Job framework.

The Standard tRouteOutput component belongs to the ESB family.

*This component is relevant only when used with one of the Talend solutions with ESB, as it should be used with the Service Repository node and the Data Service creation related wizard(s).*

**Basic settings**

| **Output Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.
Click Sync columns to retrieve the schema from the previous component connected in the Job. |
| **Built-in:** No property data stored centrally. |
| **Repository:** Select the Repository file where Properties are stored. |
| **Camel** | Enter the message parameters corresponding to the columns you defined in the schema dialog box via the Edit schema button. |
| **Type** | Select between:
**Body:** Used to set the body of a Route, equals the code exchange.getOut().setBody(...).
**Property:** Used to set the property of a Route, equals the code exchange.setProperty(name, value).
**System:** Used to set the system property, equals the code System.setProperty(name, value).
**Header:** Used the set the output header, equals the code exchange.getOut().setHeader(name, value). |
Name

This column is used to set the name for the parameter when its type is either Property, System or Header. This column is ignored when the type is Body.

Advanced settings

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at a Job level as well as at each component level.

Global Variables

Global Variables

ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule

This component can be used as the end component and thus requires an input component. It is mandatory that a tRouteInput component is used in the Data Integration Job to be called by a Route using the cTalendJob component. The reason for it is that this will prevent the referenced Job from starting automatically when deployed in Talend Runtime. Instead it will only start when it gets called by the Route.

For more information about how to use the cTalendJob component, see cTalendJob.

Limitation

The Job using a tRouteOutput must be launched only within a Route using the cTalendJob component.

Related scenario

For a scenario in which tRouteOutput is used, see Exchanging messages between a Job and a Route on page 3127.
tRowGenerator

Creates an input flow in a Job for testing purposes, in particular for boundary test sets.
tRowGenerator generates as many rows and fields as are required using random values taken from a list.

tRowGenerator Standard properties

These properties are used to configure tRowGenerator running in the Standard Job framework.
The Standard tRowGenerator component belongs to the Misc family.
The component in this framework is available in all Talend products.

Basic settings

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.
Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
• View schema: choose this option to view the schema only.
• Change to built-in property: choose this option to change the schema to Built-in for local changes.
• Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Built-In</td>
<td>You create and store the schema locally for this component only.</td>
</tr>
<tr>
<td>Repository</td>
<td>You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</td>
</tr>
</tbody>
</table>
| RowGenerator editor | The editor allows you to define the columns and the nature of data to be generated. You can use predefined routines or type in the function to be used to generate the data specified.
Note that in a Storm Job, the value -1 in the Number of rows for RowGenerator field in the RowGenerator editor means to generate infinite rows of input data. |
Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>

Usage

| Usage rule | The tRowGenerator Editor's ease of use allows users without any Java knowledge to generate random data for test purposes. |

Defining the schema

First you need to define the structure of data to be generated.

- Add as many columns to your schema as needed, using the plus (+) button.
- Type in the names of the columns to be created in the Columns area and select the Key check box if required.
- Make sure you define then the nature of the data contained in the column, by selecting the Type in the list. According to the type you select, the list of Functions offered will differ. This information is therefore compulsory.

<table>
<thead>
<tr>
<th>Column</th>
<th>Key</th>
<th>Type</th>
<th>Nullable</th>
<th>Functions</th>
<th>Preview</th>
</tr>
</thead>
<tbody>
<tr>
<td>D_employees</td>
<td></td>
<td>int</td>
<td></td>
<td>sequence</td>
<td></td>
</tr>
<tr>
<td>First_Name</td>
<td></td>
<td>String</td>
<td></td>
<td>...</td>
<td>Phoebe H</td>
</tr>
<tr>
<td>Last_Name</td>
<td></td>
<td>String</td>
<td></td>
<td>lastName</td>
<td>Eisenhower</td>
</tr>
<tr>
<td>Hire_Date</td>
<td></td>
<td>Day</td>
<td></td>
<td>getRandomDate</td>
<td>2008-08-31</td>
</tr>
</tbody>
</table>

Number of Rows for RowGenerator: 10
• Some extra information, although not required, might be useful such as Length, Precision or Comment. You can also hide these columns, by clicking on the Columns drop-down button next to the toolbar, and unchecking the relevant entries on the list.

• In the Function area, you can select the predefined routine/function if one of them corresponds to your needs. You can also add to this list any routine you stored in the Routine area of the Repository. Or you can type in the function you want to use in the Function definition panel. Related topic: see Talend Studio User Guide.

• Click Refresh to have a preview of the data generated.
• Type in a number of rows to be generated. The more rows to be generated, the longer it’ll take to carry out the generation operation.

Defining the function

Select the [...] under Function in the Schema definition panel in order to customize the function parameters.

• Select the Function parameters tab
• The Parameter area displays Customized parameter as function name (read-only)

![Function parameters](image)

• In the Value area, type in the Java function to be used to generate the data specified.
• Click on the Preview tab and click Preview to check out a sample of the data generated.

Generating random java data

The following scenario creates a two-component Job, generating 50 rows structured as follows: a randomly picked-up ID in a 1-to-3 range, a random ascii First Name and Last Name generation and a random date taken in a defined range.

• Drop a tRowGenerator and a tLogRow component from the Palette to the design workspace.
• Right-click tRowGenerator and select Row > Main. Drag this main row link onto the tLogRow component and release when the plug symbol displays.
• Double click tRowGenerator to open the Editor.
• Define the fields to be generated.
The random ID column is of integer type, the First and Last names are of string type and the Date is of date type.

In the Function list, select the relevant function or set on the three dots for custom function.

On the Function parameters tab, define the Values to be randomly picked up.

First_Name and Last_Name columns are to be generated using the getAsciiRandomString function that is predefined in the system routines. By default the length defined is 6 characters long. You can change this if need be.

The Date column calls the predefined getRandomDate function. You can edit the parameter values in the Function parameters tab.

Set the Number of Rows to be generated to 50.

Click OK to validate the setting.

Double click tLogRow to view the Basic settings. The default setting is retained for this Job.

Press F6 to run the Job.

The 50 rows are generated following the setting defined in the tRowGenerator editor and the output is displayed in the Run console.
tRSSInput

Reads RSS-Feeds using URLs. tRSSInput makes it possible to keep track of blog entries on websites to gather and organize information for quick and easy access.

**tRSSInput Standard properties**

These properties are used to configure tRSSInput running in the Standard Job framework.

The Standard tRSSInput component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Schema and Edit Schema</th>
<th>A schema is a row description, it defines the number of fields to be processed and passed on to the next component. The tRSSInput component has a read-only schema that is made of four columns: TITLE, DESCRIPTION, PUBDATE, and Link.</th>
</tr>
</thead>
<tbody>
<tr>
<td>RSS URL</td>
<td>Enter the URL for the RSS_Feed to read.</td>
</tr>
<tr>
<td>Read articles from</td>
<td>If selected, tRSSInput reads articles on the RSS_Feed from the date set through the three-dot [...] button next to the date time field.</td>
</tr>
<tr>
<td>Max number of articles</td>
<td>If selected, tRSSInput reads as many articles as the number entered in the max amount field.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>NB_LINE: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>
Usage

Usage rule

This component is generally used as an input component. It requires an output component.

Limitation

Due to license incompatibility, one or more JARs required to use this component are not provided. You can install the missing JARs for this particular component by clicking the Install button on the Component tab view. You can also find out and add all missing JARs easily on the Modules tab in the Integration perspective of your studio. You can find more details about how to install external modules in Talend Help Center (https://help.talend.com).

Fetching frequently updated blog entries.

This two-component scenario aims at retrieving frequently updated blog entries from a Talend local news RSS feed using the tRSSInput component.

Procedure

1. Drop the following components from the Palette onto the design workspace: tRSSInput and tLogRow.
2. Right-click to connect them using a Row > Main link.
3. In the design workspace, select tRSSInput, and click the Component tab to define the basic settings for tRSSInput.
   
   ![tRSSInput_1](image)
   
   **tRSSInput_1**
   
   **Basic settings**
   
   - Schema Type: [Built-in](#) Edit schema
   - RSS URL: "http://feeds.feedburner.com/Talend"
   - Read articles from date time: "2008-07-20 00:00:00"
   - Max amount: 2
   - Die on error

4. Enter the URL for the RSS Feed to access. In this scenario, tRSSInput links to the Talend RSS Feed: http://feeds.feedburner.com/Talend.
5. Select/clear the other check boxes as required. In this scenario, we want to display the information about two articles dated from July 20, 2008.
6. In the design workspace, select tLogRow and click the Component tab to define its basic settings. For more information about tLogRow properties, see tLogRow Standard properties on page 1977.
7. Save the Job and press F6 to execute it.

```
Starting job tRSSInput at 15:17 07/08/2008.

<table>
<thead>
<tr>
<th>key</th>
<th>value</th>
</tr>
</thead>
<tbody>
<tr>
<td>TITLE</td>
<td>Welcoming Jean-Luc Solans</td>

</tr>
</tbody>
</table>

#2. tLogRow_1

```

Job tRSSInput ended at 15:17 07/08/2008. [exit code=0]

The tRSSInput component accessed the RSS feed of Talend website on your behalf and organized the information for you.

Two blog entries are displayed on the console. Each entry has its own title, description, publication date, and the corresponding RSS feed URL address. Blogs show the last entry first, and you can scroll down to read earlier entries.
# tRSSOutput

Creates and writes XML files that hold RSS or Atom feeds.

## tRSSOutput Standard properties

These properties are used to configure tRSSOutput running in the Standard Job framework.

The Standard tRSSOutput component belongs to the Internet family.

The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>File name</strong></td>
<td>Name or path to the XML file to be processed and/or the variable to be used. For further information about how to define and use a variable in a Job, see <a href="https://www.talend.com">Talend Studio User Guide</a>.</td>
</tr>
<tr>
<td><strong>Encoding</strong></td>
<td>Select an encoding type from the list, or select Custom and define it manually. This field is compulsory for DB data handling.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to add the new rows to the end of the file.</td>
</tr>
<tr>
<td><strong>Mode</strong></td>
<td>Select between RSS or ATOM according to the feed you want to generate.</td>
</tr>
</tbody>
</table>

### Channel (in RSS mode)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Title</strong></td>
<td>Enter a meaningful title.</td>
</tr>
<tr>
<td><strong>Description</strong></td>
<td>Enter a description that you think will describe your content.</td>
</tr>
<tr>
<td><strong>Publication date</strong></td>
<td>Enter the relevant date.</td>
</tr>
<tr>
<td><strong>Link</strong></td>
<td>Enter the relevant URL.</td>
</tr>
</tbody>
</table>

### Feed (in ATOM mode)

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Title</strong></td>
<td>Enter a meaningful title.</td>
</tr>
<tr>
<td><strong>Link</strong></td>
<td>Enter the relevant URL.</td>
</tr>
<tr>
<td><strong>Id</strong></td>
<td>Enter the valid URL corresponding to the Link.</td>
</tr>
<tr>
<td><strong>Update date</strong></td>
<td>Enter the relevant date.</td>
</tr>
<tr>
<td><strong>Author name</strong></td>
<td>Enter the relevant name.</td>
</tr>
</tbody>
</table>

### Optionnal Channel Elements

Click the [+] button below the table to add new lines and enter the information relative to the RSS flow metadata:

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Element Name</strong></td>
<td>name of the metadata.</td>
</tr>
<tr>
<td><strong>Element Value</strong></td>
<td>content of the metadata.</td>
</tr>
</tbody>
</table>

### Schema and Edit Schema

A schema is a row description, it defines the number of fields to be processed and passed on to the next...
tRSSOutput component. The schema is either Built-in or stored remotely in the Repository.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

By default, the schema of tRSSOutput is made of five read-only columns: id, title, link, updated, and summary. You can add new columns or click Syn columns to retrieve the schema structure from the preceding component.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

- **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.
- **NB_LINE**: the number of rows read by an input component or transferred to an output component. This is an After variable and it returns an integer.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

| Usage rule | This component must be linked to an input or intermediary component. |

**Creating an RSS flow and storing files on an FTP server**

In this scenario we:
• create an RSS flow for files that you would like to share with other people, and  
• store the complete files on an FTP server.

This scenario writes an RSS feed XML file about a Mysql table holding information about books. It adds links to the files stored on an FTP server in case users want to have access to the complete files.

**Dropping and linking components**

**Procedure**

1. Drop the following components from the Palette onto the design workspace: **tMysqlInput**, **tRSSOutput**, and **tFTPPut**.
2. Right-click **tMysqlInput** and connect it to **tRSSOutput** using a **Row > Main** link.
3. Right-click **tMysqlInput** and connect it to **tFTPPut** using a **Trigger > OnSubjobOk** link.

![Diagram](image)

**Defining the data source**

**Procedure**

1. In the design workspace, select **tMysqlInput**, and click the **Component** tab to define the basic settings for **tMysqlInput**.
2. Set the **Property type** to **Repository** and click the three-dots button [...] to select the relevant DB entry from the list. The connection details along with the schema get filled in automatically.

3. In the **Table Name** field, either type your table name or click the three dots button [...] and select your table name from the list. In this scenario, the Mysql input table is called "rss_talend" and the schema is made up of four columns, **TITLE**, **Description**, **PUBDATE**, and **LINK**.

4. In the **Query** field, enter your DB query paying particular attention to properly sequence the fields in order to match the schema definition, or click **Guess Query**.

### Creating an RSS flow

#### Procedure

1. In the design workspace, select **tRSSOutput**, and click the **Component** view to define the basic settings for **tRSSOutput**.
2. In the **File name** field, use the by default file name and path, or browse to set your own for the output XML file.

3. Select the encoding type on the **Encoding Type** list.

4. In the **Mode** area, select **RSS**.

5. In the **Channel** panel, enter a title, a description, a publication date, and a link to define your input data as a whole.

6. Click **Edit Schema** to modify the schema if necessary.

   **Note:**
   
   You can click **Sync columns** to retrieve the generated schema from the preceding component.

7. Save your Job and press **F6** to execute this first part.
The tRSSOutput component created an output RSS flow in an XML format for the defined files.

**Writing the complete files to an FTP server**

**About this task**

To store the complete files on an FTP server:

**Procedure**

1. In the design workspace, select FTPPut, and click the **Component** tab to define the basic settings for tFTPPut.
2. Enter the host name and the port number in their corresponding fields.
3. Enter your connection details in the corresponding **Username** and **Password** fields.
4. Browse to the local directory, or enter it manually in the **Local directory** field.
5. Enter the details of the remote server directory.
6. Select the transfer mode from the **Transfer mode** list.
7. On the **Files** panel, click on the plus button to add new lines and fill in the filemasks of all files to be copied onto the remote directory. In this scenario, the files to be saved on the FTP server are all text files.
8. Save your Job and press **F6** to execute it.

Files defined in the Filemask are copied on the remote server.

### Creating an RSS flow that contains metadata

This scenario describes a two-component Job that creates an RSS flow that holds metadata and then redirects the obtained information in an XML file of the output RSS flow.

### Dropping and linking components

**Procedure**

1. Drop **tRSSInput** and **tRSSOutput** from the **Palette** to the design workspace.
2. Connect the two components together using a **Row > Main** link.

### Configuring the components

**Procedure**

1. Double-click **tRSSInput** to open its **Basic settings** view and define the component properties.
2. Enter the URL for the RSS_Feed to access. In this scenario, `tRSSInput` links to the Talend RSS_Feed: [http://feeds.feedburner.com/Talend](http://feeds.feedburner.com/Talend).

3. In the design workspace, double-click `tRSSOutput` to display its Basic settings view and define the component properties.

4. In the File name field, use the by default file name and path, or browse to set your own for the output XML file.

5. Select the encoding type on the Encoding Type list.

6. In the Mode area, select RSS.

7. In the Channel panel, enter a title, a description, a publication date and a link to define your input data as a whole.

8. In the Optional Channel Elements, define the RSS flow metadata. In this example, the flow has two metadata: copyright, which value is `tos`, and language which value is `en_us`.

9. Click Edit Schema to modify the schema if necessary.
Note:
You can click Sync Column to retrieve the generated schema from the preceding component.

Saving and executing the Job

Procedure

1. Press Ctrl+S to save your Job.
2. Press F6 or click Run on the Run tab to execute the Job.

The defined files are copied in the output XML file and the metadata display under the <channel> node above the information about the RSS flow.

Creating an ATOM feed XML file

This scenario describes a two component Job that generates data and writes them in an ATOM feed XML file.
Dropping and linking components

Procedure

1. Drop the following components from the Palette onto the design workspace: tFixedFlowInput of the Misc component group and tRSSOutput of the Internet component group.
2. Right-click tFixedFlowInput and connect it to tRSSOutput using a Row Main link.
3. When asked whether you want to pass on the schema of tRSSOutput to tFixedFlowInput, click Yes.

Configuring the components

Procedure

1. In the design workspace, double-click tFixedFlowInput to display its corresponding Component view and define its basic settings.
2. In the Number of rows field, leave the default setting to 1 to only generate one line of data.
3. In the Mode area, leave the Use Single Table option selected and fill in the Values table. Note that the Column field of the Values table is filled in by the columns of the schema defined in the component.
4. In the Value field of the Values table, type in the data you want to be sent to the following component.
5. In the design workspace, double-click tRSSOutput to display its corresponding Component view and define its basic settings.
6. Click the [...] button next to the **File Name** field to set the output XML file directory and name.

7. In the **Mode** area, select **ATOM** to generate an ATOM feed XML file.

**Warning:**

As the ATOM feed format is strict, some default information is required to create the XML file. So, the schema **tRSSOutput** contains default columns that will contain those information. Those default columns are greyed out to indicate that they must not be modified. If you choose to modify the schema of the component, the ATOM XML file created will not be valid.

8. In the **Feed** area, enter a title, link, id, update date, author name to define your input data as a whole.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** or click **Run** on the **Run** tab to execute the Job.
The tRSSOutput component creates an output ATOM flow in an XML format.
tRunJob

Manages complex Job systems which need to execute one Job after another.

tRunJob executes the Job called in the component’s properties, in the frame of the context defined.

**tRunJob Standard properties**

These properties are used to configure tRunJob running in the Standard Job framework.

The Standard tRunJob component belongs to the System and the Orchestration families.

The component in this framework is available in all Talend products.

**Warning:**

The tRunJob component is supported with limitations, which means that only S4 (Minor) support cases are accepted and no patches are provided. If you use tRunJob within Data Services and Routes (with cTalendJob), support is provided on a "best effort" basis only. In most cases, there are class loading issues which can sometimes be resolved but not always.

This is because tRunJob is not designed to work in a Service/Route style (ESB) deployment, so regular support is not provided if you decide to use it, even though it may work in many cases. If you used tRunJob in the past, it is recommended to change your Job Design to use Joblets instead.

For DI and non-ESB use cases, it is still a valuable component and has support.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Schema and Edit Schema</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td>A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word <strong>line</strong> when naming the fields.</td>
</tr>
<tr>
<td>Click <strong>Edit schema</strong> to make changes to the schema. If the current schema is of the <strong>Repository</strong> type, three options are available:</td>
</tr>
<tr>
<td>• <strong>View schema</strong>: choose this option to view the schema only.</td>
</tr>
<tr>
<td>• <strong>Change to built-in property</strong>: choose this option to change the schema to <strong>Built-in</strong> for local changes.</td>
</tr>
<tr>
<td>• <strong>Update repository connection</strong>: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select <strong>No</strong> upon completion and choose this schema metadata again in the <strong>Repository Content</strong> window.</td>
</tr>
</tbody>
</table>

<table>
<thead>

<tr>
<td></td>
</tr>
<tr>
<td><strong>Die on child error</strong></td>
</tr>
</tbody>
</table>
**Transmit whole context**

Select this check box to get all the context variables from the parent Job. Deselect it to get all the context variables from the child Job.

If this check box is selected when the parent and child Jobs have the same context variables defined:
- variable values for the parent Job will be used during the child Job execution if no relevant values are defined in the **Context Param** table.
- otherwise, values defined in the **Context Param** table will be used during the child Job execution.

**Context Param**

You can change the value of selected context parameters. Click the `[+]' button to add the parameters defined in the **Context tab** of the child Job. For more information on context parameters, see *Talend Studio User Guide*.

The values defined here will be used during the child Job execution even if **Transmit whole context** is selected.

**Advanced settings**

**Propagate the child result to the output schema**

Select this check box to propagate the output data stored in the buffer memory via the **tBufferOutput** component in the child Job to the output component in the parent Job.

This property takes effect only when there is data coming from an input component such as **tFixedFlowInput**.

This check box is cleared by default. It is invisible when the **Use dynamic job** or **Use an independent process to run subJob** check box is selected.

**Print Parameters**

Select this check box to display the internal and external parameters in the **Console**.

**JVM Setting**

Set JVM settings for the Job to be called or processed.

- **Use child job JVM arguments**: select this option to use the Child Job JVM arguments.
- **Overwrite child job JVM arguments**: select this option to use customized JVM arguments. To added a customized argument, click the plus button under the **JVM** frame and edit the new line added in the frame.

**tStatCatcher Statistics**

Select this check box to gather the processing metadata at the Job level as well as at each component level.

**Global Variables**

**Global Variables**

**ERROR MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.

**CHILD_RETURN_CODE**: the return code of a child Job. This is an After variable and it returns an integer.

**CHILD_EXCEPTION_STACKTRACE**: the exception stack trace from a child Job. This is an After variable and it returns a string.
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

| Usage rule | This component can be used as a standalone Job or can help clarify complex Job by avoiding having too many subjobs all together in one Job. |

| Connections | Outgoing links (from this component to another):
Row: Main.
Trigger: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error

Incoming links (from one component to this one):
Row: Main; Reject; Iterate.
Trigger: On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize.

For further information regarding connections, see Talend Studio User Guide. |

#### Calling a Job and passing the parameter needed to the called Job

This scenario describes a two-component Job named ParentJob that calls another Job named ChildJob to display the content of files specified in the ParentJob on the Run console.
Setting up the child Job

Procedure

1. Create a new Job ChildJob and add a \texttt{tFileInputDelimited} component and a \texttt{tLogRow} component to it.

2. Connect the \texttt{tFileInputDelimited} component to the \texttt{tLogRow} component using a Row > Main link.

3. Double-click the \texttt{tFileInputDelimited} component to open its Basic settings view.

4. Click in the File Name field and then press F5 to open the New Context Parameter dialog box and configure the context variable.

5. In the Name field, enter a name for this new context variable, \texttt{FilePath} in this example.

6. In the Default value field, enter the full path to the default input file.

7. Click Finish to validate the context parameter setup and fill the File Name field with the context variable.

   You can also create or edit a context parameter in the Context tab view beneath the design workspace. For more information, see \textit{Talend Studio User Guide}.

8. Click the [...] button next to Edit schema to open the Schema dialog box where you can configure the schema manually.
9. In the dialog box, click the [+ ] button to add columns and name them according to the input file structure.

   In this example, this component will actually read files defined in the parent Job, and these files contain up to five columns. Therefore, add five string type columns and name them Column1, Column2, Column3, Column4, and Column5 respectively, and then click OK to validate the schema configuration and close the Schema dialog box.

10. Double-click the tLogRow component and on its Basic settings view, select the Table option to view displayed content in table cells.

### Setting up the parent Job

**Procedure**

1. Create a new Job ParentJob and add a tFileList component and a tRunJob component to it.
2. Connect the tFileList component to the tRunJob component using a Row > Iterate link.
3. Double-click the tFileList component to open its Basic settings view.
4. In the Directory field, specify the path to the directory that holds the files to be processed, or click the [...] button next to the field to browse to the directory.

   In this example, the directory is D:/tRunJob_Input_Files that holds three delimited files with up to five columns.
5. In the FileList Type list, select Files.
6. Select the Use Glob Expressions as Filemask check box, and then click the [+ ] button to add a line in the Files area and define a filter to match files. In this example, enter " *.csv " to retrieve all delimited files.
7. Double-click the tRunJob component to display its Basic settings view.
8. Click the [...] button next to the Job field and in the pop-up dialog box, select the child Job you want to execute and click OK to close the dialog box. The name of the selected Job appears in the Job field.

9. In the Context Param area, click the [+] button to add a line and define the context parameter. The only context parameter defined in the child Job, named FilePath, appears in the Parameters cell.

10. Click in the Values cell, press Ctrl+Space on your keyboard to access the list of context variables, and select tFileList_1.CURRENT_FILEPATH.

   The corresponding context variable ((String)globalMap.get("tFileList_1_CURREN T_FILEPATH")) appears in the Values cell.

   For more information on context variables, see Talend Studio User Guide.

**Executing the parent Job**

**Procedure**

1. Press Ctrl+S to save your Jobs.

2. Press F6 to execute the parent Job.
Running a list of child jobs dynamically

This scenario describes a Job that calls specific child jobs dynamically in a given order based on a child Job list.

The child Job list can be stored in a text file, an excel file, a database table, and so on. This scenario makes sure each of the child jobs is processed using a tFlowToIterate component, which reads each row of the list and passes the child job names to a tRunJob component.

Setting up the child jobs

Procedure

1. Create a new Job named ChildJob1, and add a tFixedFlowInput component and a tLogRow component to it.

2. Connect the tFixedFlowInput component to the tLogRow component using a Row > Main connection.

3. Double-click the tFixedFlowInput component to open its Basic settings view.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, define the schema of the input data by adding one column Message of String type. When done, click OK to close the dialog box and click Yes when prompted to propagate the schema to the next component.

5. In the Mode area, select Use Single Table and enter the message you want to show on the console in the Value column of the Values table, "This is from ChildJob1..." in this example.

6. Double-click the tLogRow component and on its Basic settings view, select the Table mode to display the execution result in table cells.

7. Create five copies of this Job and name them ChildJob2, ChildJob3, ChildJob4, and ChildJob5. Enter the following messages in the Value columns of their tFixedFlowInput components: "This is from ChildJob2...", "This is from ChildJob3...", "This is from ChildJob4...", and "This is from ChildJob5...".

Creating the child Job list

About this task

The parent Job calls Child Jobs based on the child Job list. Each row in the child Job list contains a child Job name. Through the child Job list, you can impose more control over the Job execution, for example, having only part of the child Jobs executed. This can be achieved by adding a Boolean field (Execute in this scenario) in each row of the list.

Note: This scenario stores the child Job list in a text file. It can also be stored in other forms, for example, in an excel file, a database table, and so on.

To create the child Job list:

Procedure

1. Open a text editor (for example, MS notepad).
2. Type the following in the text editor.

   Job_Name, Execute
   ChildJob1, true
   ChildJob2, false
   ChildJob3, true
   ChildJob4, false
   ChildJob5, true
3. Save the file as **File_For_Execute.txt**.
4. Close the text editor.

### Setting up the parent Job

#### Procedure

1. Create a new Job named **ParentJob** and add a **tFileInputDelimited** component, a **tFlowToIterate** component, a **tRunJob**, and two **tJava** components to it.

   ![Diagram](image)

2. Connect the **tFileInputDelimited** component to the **tFlowToIterate** component using a **Row > Main** connection; the **tFlowToIterate** component to the second **tJava** component using a **Row > Iterate** connection; the second **tJava** component to the first **tJava** component using a **Trigger > Run if** connection; and the second **tJava** component to the **tRunJob** component using a **Trigger > Run if** connection.

3. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.
   - Click the [...] button next to **Edit schema** and in the pop-up dialog box, define the schema of the input data by adding two columns: **Job_Name** of String type and **Execute** of Boolean type. When done, click **OK** to close the dialog box.
   - Click the [...] button next to **File name/Stream** frame; navigate to the folder where the file **File_For_Execute.txt** resides; and select the file.
   - Type the character used to separate fields in the file **File_For_Execute.txt** in **Field Separator** (",") in this example.
   - Set the **Header** field to 1.

4. Select the connection between the two **tJava** components. Enter the following in the **Condition** field in the **Component** view to catch the rejected Jobs:

   ```java
   !((Boolean)globalMap.get("row1.Execute"))
   ```
5. Select the connection between the **tJava_2** component and the **tRunJob_1** components. Enter the following in the **Condition** field in the **Component** view to trigger the execution of the Jobs with the Execute field being true:

```
((Boolean)globalMap.get("row1.Execute"))
```

6. Double-click the **tRunJob** component to open its **Basic settings** view.

   - Select the **Use dynamic job** check box and in the **Context job** field displayed, press **Ctrl+Space** and from the list of variables select the iterative global variable created by the **tFlowToIterate** component, **tFlowToIterate_1.Job_Name** in this example. The **Context job** field is then filled with `((String)globalMap.get("row1.Job_Name"))`. Upon each iteration, this variable will be resolved as the name of the Job to be called.
   - Click the `[...]` button next to the **Job** field and in the **[Select Job]** dialog box, select all the Jobs you want to run and click **OK** to close the dialog box. In this example, they are **ChildJob1** through **ChildJob5**.

```
7. Double-click the **tJava_1** component to open its **Basic settings** view. Enter the following in the **Code** field to log the rejected child Jobs.

```java
System.out.println("----------------------------------");
System.out.println("MESSAGE : " + ((String)globalMap.get("row1.Job_Name")) + " JOB hasn't been selected for execution ... ");
System.out.println("----------------------------------");
```

**Executing the parent Job to run the child Jobs dynamically**
Procedure

1. Save your child Jobs and parent Job.
2. Press **F6** or click the **Run** button on the **Run** console to execute the Job.

As shown above, **ChildJob1**, **ChildJob3**, and **ChildJob5** were executed. This is because the **Execute** fields of these child Jobs are **true** in the **File_For_Execute.txt** file. **ChildJob2** and **ChildJob4** were not executed. This is because the **Execute** fields of these child Jobs are **false** in the **File_For_Execute.txt** file. The child Jobs were processed in the order they are listed in the **File_For_Execute.txt** file.

### Propagating the buffered output data from the child Job to the parent Job

In this scenario, a three-component Job calls a two-component child Job and displays the buffered output data of the child Job, instead of the data from the input flow of the parent Job, on the console.

### Setting up the child Job

About this task
Procedure

1. Create a Job named child, and add two components by typing their names on the design workspace or dropping them from the Palette to the design workspace:
   - a tFixedFlowInput, to generate a message
   - a tBufferOutput, to store the generated message in the buffer memory

2. Connect the tFixedFlowInput component to the tBufferOutput component using a Row > Main connection.

3. Double-click the tFixedFlowInput component to open its Basic settings view.

4. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.

5. In the Mode area, select Use Single Table option, and define the corresponding value for the message column in the Values table. In this example, the value is "message from the child job".
Setting up the parent Job

About this task

Procedure

1. Create a Job, and add three components by typing their names on the design workspace or dropping them from the Palette to the design workspace:
   - a tFixedFlowInput, to generate a message
   - a tRunJob, to call the Job named child
   - a tLogRow, to display the execution result on the console

2. Connect the tFixedFlowInput component to the tRunJob component and the tRunJob component to the tLogRow component using the Row > Main connections.

3. Double-click the tFixedFlowInput component to open its Basic settings view.

   ![Basic settings view](image)

   4. Click the [...] button next to Edit schema to open the Schema dialog box and define the schema of the input data. In this example, the schema has only one column message of the string type.

   ![Schema dialog box](image)

   When done, click OK to validate the changes.
5. In the **Mode** area, select the **Use Single Table** option, and define the corresponding value for the **message** column in the **Values** table. In this example, the value is "message from the parent job".

6. Click the **tRunJob** component and then click the **Component** tab to open its **Basic settings** view.

![Basic settings screen](image1)

7. Click the **Sync columns** button and then click **Yes** in the pop-up **Propagate** dialog box to retrieve the schema from the preceding component.

8. Click the [...] button next to the **Job** field to open the **Repository Content** dialog box.

![Repository Content dialog box](image2)

In the **Repository Content** dialog box, select the Job named **child** and then click **OK** to close the dialog box.

9. In the **Advanced settings** view of the **tRunJob** component, select the **Propagate the child result to the output schema** check box. With this check box selected, the buffered output of the child Job will be propagated to the output component.

![Advanced settings screen](image3)
Executing the parent Job

Procedure

1. Press **Ctrl+S** to save the Job.
2. Press **F6** or click the **Run** button on the **Run** console to execute the Job.

![Execution Console](image)

Starting job parent at 10:13 16/04/2014.
[statistics] connecting to socket on port 3678
[statistics] connected
message from the child job
[statistics] disconnected
Job parent ended at 10:13 16/04/2014. [exit code=0]

The child Job is called and the message specified in the child Job, rather than the message defined in the parent Job, is displayed on the console.
tS3BucketCreate

Creates a bucket on Amazon S3.

"Bucket" is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketCreate Standard properties**

These properties are used to configure tS3BucketCreate running in the Standard Job framework.

The Standard tS3BucketCreate component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td>Bucket</td>
<td>Name of the bucket, namely the top level folder, to create.</td>
</tr>
<tr>
<td>Die on error</td>
<td>This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>
### Advanced settings

| Config client | Select this check box to configure client parameters.  
| Client parameter: select client parameters from the list.  
| Value: enter the parameter value.  
| Not available when Use existing connection is selected. |
| STS Endpoint | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.  
| This check box is available only when the Assume role check box is selected. |
| Access control | Select this check box to set the access control list (ACL) for the bucket.  
| With Access control selected, click the plus button under the Access table to add a new line, where you can add an AWS user account and set permissions for it as follows.  
| • Enter the canonical user ID or the Email address of the user in double quotation marks in the Account canonical ID / email column;  
| • Select the check box in the List objects column to grant the permission to list the objects in the bucket created;  
| • Select the check box in the Write objects column to grant the permission to create, overwrite, and remove the objects in the bucket created;  
| • Select the check box in the Read bucket permissions column to grant the permission to read the ACL of the bucket created;  
| • Select the check box in the Write bucket permissions column to grant the permission to write the ACL of the bucket created. |
| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global Variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |
This variable functions only if the **Die on error** check box is selected.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component can be used alone or with other S3 components, e.g. <code>tS3BucketExist</code>.</th>
</tr>
</thead>
</table>

### Dynamic settings

Click the `[+]` button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see [Reading data from databases through context-based dynamic connections](#) on page 2446 and [Reading data from different MySQL databases using dynamically loaded connection parameters](#) on page 497. For more information on **Dynamic settings** and context variables, see [Talend Studio User Guide](#).

### Related scenario

For `tS3BucketCreate` related scenarios, see [Verifying the absence of a bucket, creating it and listing all the S3 buckets](#) on page 3176.
**tS3BucketDelete**

Deletes an empty bucket from Amazon S3.

"Bucket" is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketDelete Standard properties**

These properties are used to configure tS3BucketDelete running in the Standard Job framework. The Standard tS3BucketDelete component belongs to the Cloud family. The component in this framework is available in all Talend products.

Verifying the absence of a bucket, creating it and listing all the S3 buckets

In this scenario, `tS3BucketExist` is used to verify the absence of a bucket, `tS3BucketCreate` to create that bucket upon confirmation, and `tS3BucketList` to list all the buckets on Amazon S3.

Linking the components

Procedure
1. Drop `tS3Connection`, `tS3BucketExist`, `tS3BucketCreate`, `tS3BucketList`, `tIterateToFlow` and `tLogRow` onto the workspace.
2. Link `tS3Connection` to `tS3BucketExist` using the `OnSubjobOk` trigger.
3. Link `tS3BucketExist` to `tS3BucketCreate` using the `Run if` trigger.
4. Link `tS3BucketCreate` to `tS3BucketList` using the `OnSubjobOk` trigger.
5. Link `tS3BucketList` to `tIterateToFlow` using the `Row > Iterate` connection.
6. Link `tIterateToFlow` to `tLogRow` using the `Row > Main` connection.

Configuring the components

Procedure
1. Double-click `tS3Connection` to open its Basic settings view.

<table>
<thead>
<tr>
<th>Basic settings</th>
<th>Access Key</th>
<th>Secret Key</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>AKIAIBCZNGHY3T</td>
<td>***************</td>
</tr>
</tbody>
</table>

2. In the Access Key and Secret Key fields, enter the authentication credentials.
3. Double-click `tS3BucketExist` to open its Basic settings view.
4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** field, enter the bucket name to check if it exists.

6. Double-click the **If** link to define the condition.

   ![If1](image)

   **Basic settings**
   
   **Condition**
   
   ```java
   !((Boolean)globalMap.get("tS3BucketExist_1_BUCKET_EXIST"))
   ```

   This way, the rest of the Job will be executed if the specified bucket does not exist.

7. In the **Condition** box, enter the expression:

   ```java
   !((Boolean)globalMap.get("tS3BucketExist_1_BUCKET_EXIST"))
   ```

8. Double-click **tS3BucketCreate** to open its **Basic settings** view.

   ![tS3BucketCreate_1](image)

   Select the **Use existing connection** check box to reuse the connection.

   In the **Bucket** field, enter the bucket name to create.

9. Double-click **tS3BucketList** to open its **Basic settings** view.

   ![tS3BucketList_1](image)

   Select the **Use existing connection** check box to reuse the connection.

10. Double-click **tIterateToFlow** to open its **Basic settings** view.
11. Click **Edit schema** to open the schema editor.

Click the [+ ] button to add one column, namely **bucket_list** of the String type.

Click **Ok** to validate the setup and close the schema editor.

12. In the **Mapping** area, press **Ctrl + Space** in the **Value** field to choose the variable *tS3BucketList_1_CURRENT_BUCKET_NAME*.

13. Double-click **tLogRow** to open its **Basic settings** view.

Select **Table (print values in cells of a table)** for a better display of the results.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.
As shown above, the bucket is created and all the buckets are listed.

3. Go to the S3 web console:

As shown above, the bucket has been created on the S3 server.

4. Refresh the S3 Browser client:

This shows that the S3 Create action was performed successfully.
tS3BucketList

Lists all the buckets on Amazon S3.

“Bucket” is a term used by AWS for top level folders on S3, which can contain sub folders and store all your data (objects).

**tS3BucketList Standard properties**

These properties are used to configure tS3BucketList running in the Standard Job framework.
The Standard tS3BucketList component belongs to the Cloud family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Config client | Select this check box to configure client parameters.  
**Client parameter:** select client parameters from the list.  
**Value:** enter the parameter value. |
### STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the Assume role check box is selected.

### tStatCatcher Statistics

Select this check box to collect log data at the component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CURRENT_BUCKET_NAME</td>
<td>The current bucket name. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td>NB_BUCKET</td>
<td>The number of buckets. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

### Usage

**Usage rule**

This component can be used alone or with other S3 components, e.g. `tS3BucketDelete`.

**Dynamic settings**

Click the `[+]` button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

### Related scenario

For `tS3BucketList` related scenarios, see Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3176.
**tS3Close**

Shuts down a connection to Amazon S3, thus releasing the network resources.

**tS3Close Standard properties**

These properties are used to configure tS3Close running in the Standard Job framework.

The Standard tS3Close component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Component List</th>
<th>List of connection components.</th>
</tr>
</thead>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>ERROR_MESSAGE</th>
<th>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</th>
</tr>
</thead>
</table>

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>As an end component, this component is to be used along with other S3 components, e.g. tS3Connection.</th>
</tr>
</thead>
</table>

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenario

For `tS3Close` related scenarios, see `Listing files with the same prefix from a bucket` on page 3208.
**tS3Connection**

Establishes a connection to Amazon S3 to store and retrieve data.

**tS3Connection Standard properties**

These properties are used to configure tS3Connection running in the Standard Job framework.

The Standard tS3Connection component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume Role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session. Ensure that access to this role has been granted to your user account by the trust policy associated to this role. If you are not certain about this, ask the owner of this role or your AWS administrator.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Role ARN</strong>: the Amazon Resource Name (ARN) of the role to assume. You can find this ARN name on the Summary page of the role to be used on your AWS portal, for example, this role ARN could read like am:aws:iam:[aws_account_number]:role/[role_name].</td>
</tr>
<tr>
<td></td>
<td>• <strong>Role session name</strong>: enter the name you want to use to uniquely identify your assumed role session. This name can contain upper- and lower-case alphanumeric characters with no spaces. You can also include underscores or any of the following characters: ~, @, -</td>
</tr>
<tr>
<td></td>
<td>• <strong>Session duration (minutes)</strong>: the duration (in minutes) for which you want the assumed role session to be active. This duration cannot exceed the maximum duration which your AWS administrator has set.</td>
</tr>
</tbody>
</table>
For an example about an IAM role and its related policy types, see [Create and Manage AWS IAM Roles](https://docs.aws.amazon.com/iam/latest/UserGuide/what-is-iam.html) from the AWS documentation.

**Region**

Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. "us-east-1") in the list. For more information about the AWS Region, see [Regions and Endpoints](https://docs.aws.amazon.com/general/latest/gpo_REGIONS.html).

**Encrypt**

Select this check box and from the **Key type** drop-down list displayed, select one of the following three options for encrypting the data on the client-side before sending to Amazon S3. For more information, see [Protecting Data Using Client-Side Encryption](https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-client-side-encryption.html).

- **KMS-managed customer master key**: use a KMS-managed customer master key (CMK) for the client-side data encryption. In the **Key** field, you need to specify the AWS KMS customer master key ID (CMK ID).
- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named AES.
  - **Encoding**: select the encoding type associated with the key from the list, either Base64 or X509.
  - **Key or Key file**: specify the key or the path to the file that stores the key.
- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named RSA.
  - **Public key file**: specify the path to the public key file.
  - **Private key file**: specify the path to the private key file.

**Advanced settings**

<table>
<thead>
<tr>
<th>Use a custom region endpoint</th>
<th>Select this check box to use a custom endpoint and in the field displayed, specify the URL of the custom endpoint to be used.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Config client</strong></td>
<td>Select this check box if you want to use customized client configuration other than the default.</td>
</tr>
<tr>
<td><strong>Client Parameter</strong></td>
<td>select client parameters from the list.</td>
</tr>
<tr>
<td><strong>Value</strong></td>
<td>enter the parameter value.</td>
</tr>
<tr>
<td><strong>For related information</strong>,</td>
<td>go to <a href="https://docs.aws.amazon.com/AmazonS3/latest/userguide/using-client-side-encryption.html">Client Configuration</a>.</td>
</tr>
<tr>
<td><strong>Check S3 Accessibility</strong></td>
<td>Leave this check box selected so that the component verifies the credentials to be used for this connection request to S3 before proceeding to further actions. It is recommended to use the default <strong>By Account Owner</strong> option for this verification. The <strong>By Bucket Configuration</strong> option employs an old verification approach which</td>
</tr>
</tbody>
</table>
could significantly increase your network load in some circumstances.

<table>
<thead>
<tr>
<th><strong>Enable Accelerate Mode</strong></th>
<th>Select this check box to enable fast, easy and secure transfers of files over long distances between your client and an S3 bucket. To take it into account, you should enable this acceleration mode on the S3 bucket in advance.</th>
</tr>
</thead>
</table>
| **STS Endpoint**           | Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.  
This service allows you to request temporary, limited-privilege credentials for the AWS user you authenticate; therefore, you still need to provide the access key and secret key to authenticate the AWS account to be used.  
For a list of the STS endpoints you can use, see AWS Security Token Service. For further information about the STS temporary credentials, see Temporary Security Credentials. Both articles are from the AWS documentation.  
This check box is available only when the Assume role check box is selected. |
| **tStatCatcher Statistics**| Select this check box to collect log data at the component level. |

**Global Variables**

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| **Usage rule** | As a start component, this component is to be used along with other S3 components. |

| **Dynamic settings** | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.  
Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.  
For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
Creating an IAM role on AWS

You need an IAM role to delegate permissions to the AWS service to be used by your Job. If this IAM role does not exist, define it on AWS.

Before you begin

- You have the appropriate rights and permissions to create a new role on AWS.

Procedure

1. Log in to your account on AWS and navigate to the AWS console.
2. Select IAM.
3. In the navigation pane of the IAM console, select Roles, and then select Create role.
4. Select AWS service and in the Choose the service that will use this role section, select the AWS service to be run with your Job. For example, select Redshift.
5. Select the use case to be used for this service. An use case in terms of AWS is defined by the service to include the trust policy that this service requires. Depending on the service and the use case that you selected, the available options vary. For example, with Redshift, you can choose an use case from:
   - Redshift (with a pre-defined Amazon Redshift Service Linked Role Policy);
   - Redshift - Customizable. In this use case, you are prompted to select either read-only policies or full-access policies.
6. In the Role name field, enter the name to be used for the role being created.
7. Select Create role.

Results

A custom role has been created to delegate permissions to an AWS service. For the full documentation about creating a role on AWS, see Role creation from the AWS documentation.

Setting up SSE KMS for your EMR cluster

If required by the security policy of your organization, you need to set up SSE KMS, the server-side encryption service of Amazon, for the EMR cluster to be used, before creating this cluster.

About this task

This procedure explains only the SSE KMS related operations for getting started with the security configuration for EMR. If you need the complete information about all the available EMR security configurations provided by AWS, see Create a Security Configuration from the Amazon documentation.

Procedure

1. If not yet done, go to https://console.aws.amazon.com/kms to create a customer managed CMK to be used by the SSE KMS service. For detailed instructions about how to do this, see this tutorial from the AWS documentation.
   - When adding roles, among other roles to be added depending on your security policy, you must add the EMR_EC2_DefaultRole role.
The EMR_EC2_DefaultRole role allows your Jobs for Apache Spark to read or write files encrypted with SSE-KMS on S3.

This role is a default AWS role that is automatically created along with the creation of your first EMR cluster. If this role and its associated policies do not exist in your account, see Use Default IAM Roles and Managed Policies from the AWS documentation.

2. On the Amazon EMR page of AWS, select the Security configurations tab and click Create to open the Create security configuration view.

3. Select the At-rest encryption check box to enable SSE KMS.

4. Under S3 data encryption, select SSE-KMS for Encryption mode and select the CMK key mentioned at the beginning of this procedure for AWS KMS Key.

5. Under Local disk encryption, select AWS KMS for Key provider type and select the CMK key mentioned at the beginning of this procedure for AWS KMS Key.

Example

Create security configuration

Name: your_security_config_name

Encryption

At-rest encryption

S3 encryption

Encryption mode: SSE-KMS

AWS KMS Key: cmk123

Local disk encryption

Key provider type: AWS KMS

AWS KMS Key: cmk123

6. Click Create to validate your security configuration.

In the real-world practice, you can also configure the other security options such as Kerberos and IAM roles for EMRFS before clicking this Create button.

7. Click Clusters and once the Create Cluster page is open, click Go to advanced options to start creating the EMR cluster step by step.

8. At the last step called Security, in the Authentication and encryption section, select the Security Configuration created in the previous steps.
Setting up SSE KMS for your S3 bucket

If required by the security policy of your organization, you need to set up SSE KMS for the S3 bucket to be used.

Before you begin
Prerequisite: you must have created the CMK key to be used. For detailed instructions about how to do this, see this tutorial from the AWS documentation.

About this task
This procedure explains only the SSE KMS related operations for getting started with the security configuration for EMR. If you need the complete information about all the available EMR security configurations provided by AWS, see Create a Security Configuration from the Amazon documentation.

Procedure
1. Open your S3 service at https://s3.console.aws.amazon.com/.
2. From the S3 bucket list, select the bucket to be used. Ensure that you have proper rights and permissions to access this bucket.
3. Select the Properties tab and then Default encryption.
4. Select AWS-KMS.
5. Select the KMS CMK key to be used.
6. **Select the Permissions tab, then select Bucket Policy and enter your policy in the console.** This article from AWS provides detailed explanations and a simple policy example: *How to Prevent Uploads of Unencrypted Objects to Amazon S3.*

7. **Click Save to save your policy.**

**Results**

Now your bucket policy is set up. When you need to use this bucket with a Job, enter the following parameter about AWS signature versions to the JVM argument list of this Job:

```-Dcom.amazonaws.services.s3.enableV4```
For further information about AWS Signature Versions, see Specifying the Signature Version in Request Authentication.

**Related scenario**

For **tS3Connection** related scenarios, see Exchange files with Amazon S3 on page 3218.
tS3Copy

Copies an Amazon S3 object from a source bucket to a destination bucket.

**tS3Copy Standard properties**

These properties are used to configure tS3Copy running in the Standard Job framework.

The Standard tS3Copy component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Use an existing connection</strong></td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td><strong>Access Key</strong></td>
<td>Specify the Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td><strong>Secret Key</strong></td>
<td>Specify the Secret Access Key, constituting the security credentials in combination with the access key.</td>
</tr>
<tr>
<td></td>
<td>To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td><strong>Inherit credentials from AWS role</strong></td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td><strong>Assume role</strong></td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td><strong>Region</strong></td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td><strong>Source Bucket</strong></td>
<td>Specify the name of the source bucket that contains the object to be copied.</td>
</tr>
<tr>
<td><strong>Source Key</strong></td>
<td>Specify the path to the object to be copied.</td>
</tr>
<tr>
<td></td>
<td><strong>Warning:</strong> This field must not start with a slash (/).</td>
</tr>
<tr>
<td><strong>Destination Bucket</strong></td>
<td>Specify the name of the destination bucket to which the object will be copied.</td>
</tr>
</tbody>
</table>
| **Destination Key** | Specify the path to the destination object, using slash (/) to separate folders in the path.  
If:  
- you only specify a file name in this field, the file will be in the bucket;  
- the path contains folders that do not exist, the folders will be created;  
- the file already exists, it will be overwritten.  
**Warning:** This field must not start with a slash (/). |
| **Server-Side Encryption** | Select this check box to enable server-side encryption with Amazon S3-Managed Encryption Keys (SSE-S3) and use the 256-bit Advanced Encryption Standard (AES-256) cipher to encrypt your data.  
For more information about the server-side encryption, see [Protecting Data Using Server-Side Encryption](#). |
| **Use KMS** | Select this check box to enable server-side encryption with AWS KMS-Managed Keys (SSE-KMS) instead of Amazon S3-Managed Encryption Keys (SSE-S3).  
This property is available when the Server-Side Encryption check box is selected. |
| **Customer Master Key** | Specify your own customer master key (CMK) that is created in the IAM console using AWS Key Management Service for SSE-KMS encryption. If not specified, the default CMK, which is created the first time you add an SSE-KMS encrypted object to the defined bucket in your region, will be used for SSE-KMS encryption.  
This property is available when the Use KMS check box is selected. |
| **Die on error** | Select this check box to stop the execution of the Job when an error occurs.  
Clear the check box to skip any rows on error and complete the process for error-free rows. |

**Advanced settings**

| **Config client** | Select this check box and specify the client parameter(s) by clicking the [+] button to add as many rows as needed, each row for a client parameter, and then setting the value of the following fields for each parameter:  
- **Client Parameter:** click the cell and from the drop-down list displayed select the client parameter.  
- **Value:** enter the value for the selected parameter.  
This check box is available only when the Use an existing connection check box is cleared. |
| **Part size (Mb) for file larger than 5GB** | Specify the part size in MB. This parameter takes effect only when you copy an Amazon S3 object that is larger than 5 GB through multiple parts.  
Note that in the copy operation, the object's metadata may drop during transition. |
STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the Assume role check box is selected.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.

### Usage

**Usage rule**

This component can be used as a standalone component.

### Copying an S3 object from one bucket to another

This scenario describes a Job that uploads a new object to an existing empty S3 bucket `bucket-src`, then copies the object from the bucket `bucket-src` to another existing empty S3 bucket `bucket-dst`, finally lists the object in the bucket `bucket-dst` to see whether the object is successfully copied.
Setting up the Job

Procedure

1. Create a new Job and add a **tS3Connection** component, a **tS3Put** component, a **tS3Copy** component, a **tS3List** component, a **tIterateToFlow** component, and a **tLogRow** component by typing their names on the design workspace or dropping them from the Palette.

2. Link the **tS3List** component to the **tIterateToFlow** component using a Row > Iterate connection.

3. Link the **tIterateToFlow** component to the **tLogRow** component using a Row > Main connection.

4. Link the **tS3Connection** component to the **tS3Put** component using a Trigger > On Subjob Ok connection.

5. Do the same to link the **tS3Put** component to the **tS3Copy** component and the **tS3Copy** component to the **tS3List** component.

Configuring the components

Creating a connection to Amazon S3

Procedure

1. Double-click the **tS3Connection** component to open its Basic settings view on the Component tab.

   ![tS3Connection](image)

   - In the Access Key and Secret Key fields, enter the authentication credentials required to access Amazon S3.
   - From the Region drop-down list, select an AWS region where the object will be uploaded and copied. In this example, we keep the default setting.

Uploading an object to an Amazon S3 bucket

Procedure

1. Double-click the **tS3Put** component to open its Basic settings view on the Component tab.

   ![tS3Put](image)
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field, enter the name of the S3 bucket where the object will be uploaded. In this example, it is *bucket-src* that already exists in Amazon S3.

4. In the **Key** field, enter the key for the object to be uploaded. In this example, it is *tS3Copy_icon32_src.png*.

5. In the **File** field, browse to or enter the path to the object to be uploaded. In this example, it is *D:/tS3Copy_icon32.png*.

### Copying the uploaded object to another Amazon S3 bucket

**Procedure**

1. Double-click the **tS3Copy** component to open its **Basic settings** view on the **Component** tab.

   - **Basic settings**
     - **Connection**
       - **Use an existing connection**
     - **Source Configuration**
       - **Bucket** *bucket-src*
       - **Key** *tS3Copy_icon32_src.png*
     - **Destination Configuration**
       - **Bucket** *bucket-dst*
       - **Key** *tS3Copy_icon32_dst.png*

   - **Server-Side Encryption**
   - **Die on error**

2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. In the **Bucket** field in the **Source Configuration** area, enter the name of the bucket which contains the object to be copied. In this example, it is *bucket-src*.

4. In the **Key** field in the **Source Configuration** area, enter the key of the object to be copied. In this example, it is *tS3Copy_icon32_src.png*.

5. In the **Bucket** field in the **Destination Configuration** area, enter the name of the bucket to which the object will be copied. In this example, it is the empty one *bucket-dst* that already exists in Amazon S3.

6. In the **Key** field in the **Destination Configuration** area, enter the new key for the object after being copied to the destination bucket. In this example, it is *tS3Copy_icon32_dst.png*.

### Listing the object in the destination bucket

**Procedure**

1. Double-click the **tS3List** component to open its **Basic settings** view on the **Component** tab.
2. Select the **Use an existing connection** check box to reuse the Amazon S3 connection information you have defined in the **tS3Connection** component.

3. Clear the **List all buckets objects** check box, and then click the [+ ] button to add one row in the **Bucket** table displayed and set the value for each column. In this example, `bucket-dst` for the **Bucket name** column and empty value for the **Key prefix** column, this way only the objects in the `bucket-dst` bucket will be listed.

4. Double-click the **tIterateToFlow** component to open its **Basic settings** view on the **Component** tab.

5. Click the [...] button next to **Edit schema** and in the pop-up schema dialog box define the schema by adding one column **ObjectList** of **String** type.

6. Click **OK** to save the changes and in the pop-up dialog box click **Yes** to accept the propagation.

7. Double-click the **tLogRow** component to open its **Basic settings** view on the **Component** tab.
8. In the **Mode** area, select **Table** (*print values in cells of a table*) for better readability of the result.

## Saving and executing the Job

### Procedure

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```
[statistics] connecting to socket on port 3491
[statistics] connected
<table>
<thead>
<tr>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>tLogRow_1</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
<tr>
<td>ObjectList</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
<tr>
<td>tS3Copy_icon32_dat.png</td>
</tr>
<tr>
<td>--------------------------------</td>
</tr>
</tbody>
</table>

[statistics] disconnected
```

As shown above, the uploaded object has been copied to the destination bucket successfully.
tS3Delete

Deletes a file from Amazon S3.

**tS3Delete Standard properties**

These properties are used to configure tS3Delete running in the Standard Job framework.

The Standard tS3Delete component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td>Bucket</td>
<td>Specify the name of the bucket, namely the top level folder, on Amazon S3.</td>
</tr>
<tr>
<td>Key</td>
<td>Specify the path to the file to delete. <strong>Warning:</strong> This field must not start with a slash (/).</td>
</tr>
</tbody>
</table>
### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

### Advanced settings

**Config client**

Select this check box to configure client parameters.

- **Client parameter**: select client parameters from the list.
- **Value**: enter the parameter value.

Not available when *Use existing connection* is selected.

**STS Endpoint**

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the *Assume role* check box is selected.

**tStatCatcher Statistics**

Select this check box to collect log data at the component level.

### Global Variables

**ERROR_MESSAGE**

The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the *Die on error* check box is selected.

### Usage

**Usage rule**

This component can be used alone or with other S3 components, e.g. tS3BucketList.

**Dynamic settings**

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenario

For **tS3Delete** related scenarios, see Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3176.
tS3Get

Retrieves a file from Amazon S3.

**tS3Get Standard properties**

These properties are used to configure tS3Get running in the Standard Job framework.

The Standard tS3Get component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Setting</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit <a href="#">Getting Your AWS Access Keys</a>.</td>
</tr>
<tr>
<td>Secret Key</td>
<td>The Secret Access Key, constituting the security credentials in combination with the access key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see <a href="#">Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances</a>.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see <a href="#">Regions and Endpoints</a>.</td>
</tr>
<tr>
<td>Client-side Encrypt</td>
<td>Select this check box and from the <strong>Key type</strong> drop-down list displayed, select one of the following three options for encrypting the data on the client-side before sending to Amazon S3. For more information, see <a href="#">Protecting Data Using Client-Side Encryption</a>.</td>
</tr>
<tr>
<td></td>
<td><strong>KMS-managed customer master key</strong>: use a KMS-managed customer master key (CMK) for the client-side data encryption. In the <strong>Key</strong> field, you need to specify the AWS KMS customer master key ID (CMK).</td>
</tr>
</tbody>
</table>
- **Symmetric Master Key**: use a symmetric master key (256-bit AES secret key) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named AES.
  - **Encoding**: select the encoding type associated with the key from the list, either Base64 or X509.
  - **Key** or **Key file**: specify the key or the path to the file that stores the key.
- **Asymmetric Master Key**: use an asymmetric master key (a 1024-bit RSA key pair) for the client-side data encryption.
  - **Algorithm**: select the algorithm associated with the key from the list. By default, there is only one algorithm named RSA.
  - **Public key file**: specify the path to the public key file.
  - **Private key file**: specify the path to the private key file.

<table>
<thead>
<tr>
<th>Bucket</th>
<th>Specify the name of the bucket, namely the top level folder, on the S3 server.</th>
</tr>
</thead>
<tbody>

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

**Related scenario**

For **tS3Get** related scenarios, see Exchange files with Amazon S3 on page 3218.
tS3List

Lists the files on Amazon S3 based on the bucket/file prefix settings.

**tS3List Standard properties**

These properties are used to configure tS3List running in the Standard Job framework.

The Standard tS3List component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Access Key</td>
<td>The Access Key ID that uniquely identifies an AWS Account. For how to get your Access Key and Access Secret, visit Getting Your AWS Access Keys.</td>

<td>The Secret Access Key, constituting the security credentials in combination with the access Key. To enter the secret key, click the [...] button next to the secret key field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Inherit credentials from AWS role</td>
<td>Select this check box to obtain AWS security credentials from Amazon EC2 instance metadata. To use this option, the Amazon EC2 instance must be started and your Job must be running on Amazon EC2. For more information, see Using an IAM Role to Grant Permissions to Applications Running on Amazon EC2 Instances.</td>
</tr>
<tr>
<td>Assume role</td>
<td>If you temporarily need some access permissions associated to an AWS IAM role that is not granted to your user account, select this check box to assume that role. Then specify the values for the following parameters to create a new assumed role session.</td>
</tr>
<tr>
<td>Region</td>
<td>Specify the AWS region by selecting a region name from the list or entering a region between double quotation marks (e.g. &quot;us-east-1&quot;) in the list. For more information about the AWS Region, see Regions and Endpoints.</td>
</tr>
<tr>
<td>List all bucket objects</td>
<td>Select this check box to list all the files on the S3 server. <strong>Key prefix:</strong> enter the prefix of files to be listed. This way, only files with that prefix will be listed.</td>
</tr>
<tr>
<td>Bucket</td>
<td>Click the [*] button to add one or more lines for defining the buckets and file prefixes. <strong>Bucket name:</strong> name of the bucket, namely the top level folder, whose files will be listed. <strong>Key prefix:</strong> prefix of files to be listed.</td>
</tr>
</tbody>
</table>
Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

Advanced settings

Config client

Select this check box to configure client parameters.

Client parameter: select client parameters from the list.

Value: enter the parameter value.

Not available when Use existing connection is selected.

STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, sts.amazonaws.com, where session credentials are retrieved from.

This check box is available only when the Assume role check box is selected.

tStatCatcher Statistics

Select this check box to collect log data at the component level.

Global Variables

CURRENT_BUCKET_NAME

The current bucket name. This is a Flow variable and it returns a string.

CURRENT_KEY

The current key. This is a Flow variable and it returns a string.

NB_BUCKET

The number of buckets. This is an After variable and it returns an integer.

NB_BUCKET_OBJECT

The number of objects in all buckets. This is an After variable and it returns an integer.

ERROR_MESSAGE

The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.

Usage

Usage rule

This component can be used alone or with other S3 components, e.g. tS3Delete.

Dynamic settings

Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.
Once a dynamic parameter is defined, the **Component List** box in the **Basic settings** view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on **Dynamic settings** and context variables, see Talend Studio User Guide.

---

### Listing files with the same prefix from a bucket

In this scenario, **tS3List** is used to list all the files in a bucket which have the same prefix.

There are such files in this bucket:

![Image of S3 Browser](image)

For how to create a bucket and put files into it, see Verifying the absence of a bucket, creating it and listing all the S3 buckets on page 3176 and Exchange files with Amazon S3 on page 3218.

#### Linking the components

**Procedure**

1. Drop **tS3Connection**, **tS3List**, **tIterateToFlow**, **tLogRow** and **tS3Close** onto the workspace.
2. Link **tS3Connection** to **tS3List** using the **OnSubjobOk** trigger.
3. Link **tS3List** to **tIterateToFlow** using the **Row > Iterate** connection.
4. Link **tIterateToFlow** to **tLogRow** using the **Row > Main** connection.
5. Link **tS3List** to **tS3Close** using the **OnSubjobOk** trigger.
Configuring the components

Procedure

1. Double-click tS3Connection to open its Basic settings view.

2. In the Access Key and Secret Key fields, enter the authentication credentials.

3. Double-click tS3List to open its Basic settings view.
4. Select the **Use existing connection** check box to reuse the connection.

5. In the **Bucket** area, click the [+] button to add one line.

6. In the **Bucket name** and **Key prefix** fields, enter the bucket name and file prefix. This way, only files with the specified prefix will be listed.

7. Double-click **tIterateToFlow** to open its **Basic settings** view.

![tIterateToFlow](image)

8. Click **Edit schema** to open the schema editor.

![Schema of tIterateToFlow](image)

Click the [+] button to add one column, namely **file_list** of the String type. Click **Ok** to validate the setup and close the schema editor.

9. In the **Mapping** area, press **Ctrl + Space** in the **Value** field to choose the variable **tS3List_1_CURRENT_KEY**.

10. Double-click **tLogRow** to open its **Basic settings** view.

![tLogRow](image)

Select **Table (print values in cells of a table)** for a better display of the results.

11. Double-click **tS3Close** to open its **Basic settings** view.
There is no need to select a connection component as the only one is selected by default.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

    ![Code Output]

    As shown above, only the files with the prefix "in" are listed.
Tagging S3 objects

This scenario shows the way to add tags to S3 objects using S3 SDK for Java.

This scenario assumes that you have a valid S3 user account and the S3 objects (file1.txt, file2.txt, and file3.txt in this example) reside under the S3 bucket.

Tagging S3 objects: linking the components

Procedure
1. Drop tS3Connection, tS3List, tJavaFlex, and tSClose onto the workspace.
2. Link tS3Connection to tS3List using the OnSubjobOk trigger.
3. Link tS3List to tJavaFlex using the Iterate trigger.
4. Link tS3Connection to tS3List using the OnSubjobOk trigger.

Tagging S3 objects: configuring the components

Procedure
1. Double-click tS3Connection to open its Basic settings view.

   a) In the Access Key and Secret Key fields, enter the authentication credentials.
   b) Set the Region option.
2. Double-click **tS3List** to open its **Basic settings** view.

   ![Basic settings view]

   a) Select the **Use existing connection** check box to reuse the connection.
   
   b) In the **Bucket name** field, enter the bucket name.
   
   c) In the **Key prefix** field, enter the prefix of the files to add the tag to ("file" in this example).

3. Double-click **JavaFlex** to open its **Basic settings** view.

   a) Copy-paste the following code into the **Start code** field.

   ```java
   com.amazonaws.services.s3.AmazonS3Client s3Client = (com.amazonaws.services.s3.AmazonS3Client) globalMap.get("conn_tS3Connection_1");
   List<Tag> myTags = new ArrayList<Tag>();
   ```

   b) Copy-paste the following code into the **Main code** field.

   ```java
   myTags.add(new Tag("Tag1", "Tag1 value"));
   s3Client.setObjectTagging(new SetObjectTaggingRequest("compdoc-bucket", (String)globalMap.get("tS3List_1_CURRENT_KEY")), new ObjectTagging(myTags));
   ```

   c) In the **Advanced settings** view, copy-paste the following into the **Import** field.

   ```java
   import com.amazonaws.AmazonServiceException;
   import com.amazonaws.SdkClientException;
   import com.amazonaws.auth.profile.ProfileCredentialsProvider;
   import com.amazonaws.regions.Regions;
   import com.amazonaws.services.s3.AmazonS3;
   import com.amazonaws.services.s3.AmazonS3ClientBuilder;
   import com.amazonaws.services.s3.model.*;
   import java.io.File;
   import java.util.ArrayList;
   import java.util.List;
   ```

   **Note:** For information about the code blocks in this step, see Managing Tags Using the AWS SDK for Java.

4. Double-click **tS3Close** and make sure **tS3Connection_1** appears in the **Component List** drop-down list.

---

### Tagging S3 objects: executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

3. Go to the S3 web console, select *file1.txt*, and click **Tags**. The tag added to the object appears, as shown in the following figure.

4. Deselect *file1.txt* and select the other two files separately, you can find that both of the two files have the same tag and the same tag value.
tS3Put

Uploads data onto Amazon S3 from a local file or from cache memory via the streaming mode.

**tS3Put Standard properties**

These properties are used to configure tS3Put running in the Standard Job framework. The Standard tS3Put component belongs to the Cloud family. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>Use existing connection</strong></th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>

<td><strong>Server-Side Encryption</strong></td>
<td>Select this check box to enable server-side encryption with Amazon S3-Managed Encryption Keys (SSE-S3) and use the 256-bit Advanced Encryption Standard (AES-256) cipher to encrypt your data. For more information about the server-side encryption, see Protecting Data Using Server-Side Encryption.</td>
</tr>
<tr>
<td><strong>Use KMS</strong></td>
<td>Select this check box to enable server-side encryption with AWS KMS-Managed Keys (SSE-KMS) instead of Amazon S3-Managed Encryption Keys (SSE-S3). This property is available when the Server-Side Encryption check box is selected.</td>
</tr>
</tbody>
</table>
| **Customer Master Key** | Specify your own customer master key (CMK) that is created in the IAM console using AWS Key Management Service for SSE-KMS encryption. If not specified, the default CMK, which is created the first time you add an SSE-KMS
encrypted object to the defined bucket in your region, will be used for SSE-KMS encryption. This property is available when the **Use KMS** check box is selected.

### Die on error

This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.

## Advanced settings

### Config client

Select this check box to configure client parameters.

- **Client parameter**: select client parameters from the list.
- **Value**: enter the parameter value.

Not available when **Use existing connection** is selected.

### Enable Accelerate Mode

Select this check box to enable fast, easy and secure transfers of files over long distances between your client and an S3 bucket. To take it into account, you should enable this acceleration mode on the S3 bucket in advance.

### STS Endpoint

Select this check box and in the field displayed, specify the AWS Security Token Service endpoint, for example, `sts.amazonaws.com`, where session credentials are retrieved from.

This check box is available only when the **Assume role** check box is selected.

### Part size (Mb)

Specify the part size (in MB) when uploading an object in parts.

Part size is in the range 5MB to 5GB. A value less than 5 uploads the object with the part size of 5MB. For an object that is less than 5GB in size, you can have it uploaded without being divided into parts by setting this option to a large enough value.

For information about S3 multipart upload, see [Multipart Upload Overview](#).

### Access control

Select this check box to set the access control list (ACL) for the current object.

With **Access control** selected, click the plus button under the **Access** table to add a new line, where you can add an AWS user account and set permissions for it as follows.

- Enter the canonical user ID or the Email address of the user in double quotation marks in the **Account canonical ID / email** column;
- Select the check box in the **Read object** column to grant the permission to read the data and metadata of the object in the bucket;
- Select the check box in the **Read object permissions** column to grant the permission to read the ACLs of the object in the bucket;
- Select the check box in the **Write object permissions** column to grant the permission to write the ACLs of the object in the bucket.
**tS3Put**

<table>
<thead>
<tr>
<th><strong>tStatCatcher Statistics</strong></th>
<th>Select this check box to collect log data at the component level.</th>
</tr>
</thead>
</table>

### Global Variables

<table>
<thead>
<tr>
<th><strong>ERROR_MESSAGE</strong></th>
<th>The error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is selected.</th>
</tr>
</thead>
</table>

### Usage

<table>
<thead>
<tr>
<th><strong>Usage rule</strong></th>
<th>This component can be used alone or with other S3 components, e.g. tS3Connection.</th>
</tr>
</thead>
</table>

| **Dynamic settings** | Click the [+1 button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. 

Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. 

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |
|---------------------|------------------------------------------------------------------------------------------------------------------|

---

**Exchange files with Amazon S3**

In this scenario, **tS3Put** is used to send a file to the Amazon S3 server while **tS3Get** is used to get that file.
Linking the components

Procedure

1. Drop tS3Connection, tS3Put and tS3Get onto the workspace.
2. Link tS3Connection to tS3Put using the OnSubjobOk trigger.
3. Link tS3Put to tS3Get using the OnSubjobOk trigger.

Configuring the components

Procedure

1. Double-click tS3Connection to open its Basic settings view.

   - In the Access Key and Secret Key fields, enter the authentication credentials.

2. Double-click tS3Put to open its Basic settings view.

   - Connection
   - Bucket: "movies_andy"
   - Key: "action_movie.json"
   - File: "D:/action_movie.json"
   - Server-Side Encryption
   - Die on error
4. Select the **Use existing connection** check box to reuse the connection.
5. In the **Bucket** field, enter the bucket name.
6. In the **Key** field, enter the name of the file to be saved on the S3 server.
7. In the **File** field, enter the file to be uploaded to the S3 server.
8. Double-click tS3Get to open its **Basic settings** view.

![tS3Get 1](image)

9. Select the **Use existing connection** check box to reuse the connection.
10. In the **Bucket** field, enter the bucket name.
11. In the **Key** field, enter the name of the file to be retrieved from the S3 server.
12. In the **File** field, enter the local name of the retrieved file.

### Executing the Job

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job.

```plaintext
Starting job s3_put_get at 14:22 08/10/2013:
[statistics] connecting to socket on port 3950
[statistics] connected
[statistics] disconnected
Job s3_put_get ended at 14:22 08/10/2013. [exit code=0]
```
3. Go to the S3 web console:

![S3 Management Console](image)

As shown above, the file has been put on to the S3 server.

4. Refresh the S3 Browser client:
This shows that the S3 Put action was performed successfully.

5. Go to the folder where the retrieved file is saved locally:

As shown above, the remote file is retrieved to the local disk, proof that the S3 Get action was performed successfully.
**tSalesforceBulkExec**

Bulk-loads data in a given file into a Salesforce object.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

**tSalesforceBulkExec Standard properties**

These properties are used to configure tSalesforceBulkExec running in the Standard Job framework.

The Standard tSalesforceBulkExec component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>

<td>Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field.</td>
</tr>
</tbody>
</table>
| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - View schema: choose this option to view the schema only.  
  - Change to built-in property: choose this option to change the schema to Built-in for local changes.  
  - Update repository connection: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job. |                                                                                                |
| Output Action     | Select one of the following operations to be performed from the drop-down list.                                                                                                                                 |                                                                                                |
• **INSERT**: insert one or more new records into Salesforce.
• **UPDATE**: update one or more existing records in Salesforce.
• **UPSERT**: create new records or update existing records. In the **Upsert Key Column** field displayed, specify the key column for the upsert operation. By selecting **Output upsert column**, a column named **UpsertColumnValue** will be added to the output schema. The column holds upsert key values and thus can be used to monitor the upsert key. You can select **Output upsert column** if the upsert key is a variable.
• **DELETE**: delete one or more records in Salesforce.

| Bulk File Path | Specify the path to the file that stores the data to be processed. |

**Advanced settings**

| Salesforce URL | The Webservice URL required to connect to Salesforce. |
| API version | The Salesforce API version. This property is available only when the OAuth connection type is selected. |
| Need compression | Select this check box to activate SOAP message compression, which can result in increased performance levels. |
| Trace HTTP message | Select this check box to output the HTTP interactions on the console. |
| Client Id | Enter the ID of the real user to differentiate between those who use the same account and password to access the Salesforce website. |
| Timeout | Enter the intended number of query timeout in milliseconds in Salesforce. |
| Use Proxy | Select this check box to use a proxy server, and in the Host, Port, User Id, and Password fields displayed, specify the connection parameters of the proxy server. |
| Bulk API V2 | Select this checkbox to create a Bulk API V2 job, and then select a type of field delimiter from the **Column Delimiter** drop-down list and a way of line ending from the **Line Ending** drop-down list respectively for CSV data. Compared with Bulk API V1, Bulk API v2 simplifies the way of processing data. This property is available only when the OAuth connection type is selected. |
| Concurrency Mode | Select the concurrency mode for the job. |
| | • **Parallel**: process batches in parallel mode. |
| | • **Serial**: process batches in serial mode. |
| Rows to Commit | Specify the number of lines per data batch to be processed. |
### tSalesforceBulkExec

### Related scenario

No scenario is available for this component yet.
tSalesforceConnection

Opens a connection to Salesforce.

**tSalesforceConnection Standard properties**

These properties are used to configure tSalesforceConnection running in the Standard Job framework. The Standard tSalesforceConnection component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Property Type</strong></td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td><strong>Built-In</strong></td>
<td>The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
</tbody>
</table>

**Connection type**

Select the type of the connection from the drop-down list. The connection properties will vary according to the connection type you choose.

- **Basic**: select this option to access Salesforce by entering your Salesforce username and password.
- **OAuth**: select this option to access Salesforce using OAuth (Open Authorization) 2.0 protocol to authenticate the user. From the OAuth2 flow type drop-down list displayed, you need to choose an OAuth 2.0 authentication flow type, either Json Web Token Flow or Implicit Flow (Deprecated) (User Agent Flow). This way, you need to create a connected app in Salesforce to configure a Salesforce authentication provider. For more information about the OAuth authentication flow, see Authenticate Apps with OAuth. For more information about how to create a connected app in Salesforce, see Create a Connected App.

**User Id**

The Salesforce username. This property is available only when the **Basic** connection type is selected.

**Password**

The Salesforce password associated with the username. This property is available only when the **Basic** connection type is selected.

**Security Token**

The Salesforce security token. For more information, see Reset Your Security Token.

</tr>
</tbody>
</table>

**Global Variables**

| **ERROR_MESSAGE** | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| **Usage rule** | This component is more commonly used with other Salesforce components. |

**Connecting to Salesforce using OAuth implicit flow to authenticate the user (deprecated)**

In this scenario, the **OAuth2** (Open Authorization 2.0) method is adopted to authorize **tSalesforceConnection** to access the Salesforce resources. This way, better security is achieved as users do not need entering their Salesforce username/password directly on **tSalesforceConnection**, which is required by the **Basic** login type instead.

**Setting up the Job**

**Procedure**

1. Drop a **tSalesforceConnection** component, a **tFixedFlowInput** component and a **tSalesforceOutput** component onto the workspace.
2. Link the **tFixedFlowInput** component to the **tSalesforceOutput** component using a **Row > Main** connection.
3. Link the **tSalesforceConnection** component to the **tFixedFlowInput** component using a **Trigger > OnSubjobOk** connection.

**Configuring the components**

**Procedure**

1. Double-click the **tSalesforceConnection** component to open its **Basic settings** view.

   ![tSalesforceConnection Basic settings](image)

   - **Basic settings**
     - **Property Type**: Built-In
     - **Connection type**: OAuth
     - **OAuth2 flow type**: Implicit Flow
     - **Client Id**: ansfiveadsfawd
     - **Client Secret**: ***************
     - **Callback Host**: localhost
     - **Callback Port**: 8089
     - **Token File**: D:/tokenfile.txt

2. Select **OAuth** from the **Connection type** drop-down list and **Implicit Flow** from the **Oauth2 flow type** drop-down list.

3. In the **Client Id** and **Client Secret** fields, enter the key and secret used by the consumer to access Salesforce respectively.

4. In the **Callback Host** and **Callback Port** fields, enter the callback host and port information respectively.

5. In the **Token File** field, browse to or enter the path to the token file that stores the refresh token used by the OAuth-enabled connected app to obtain new sessions without requiring the user to provide their credentials.

6. Double-click the **tFixedFlowInput** component to open its **Basic settings** view.

   ![tFixedFlowInput Basic settings](image)

   - **Basic settings**
     - **Number of rows**: 1
     - **Schema**: Build-In

7. Click the **[...]** button next to **Edit schema** and in the pop-up schema dialog box, define the schema by adding one column **Name** of String type. When done, click **OK** to save the changes and close the dialog box.
8. In the **Mode** area, select **Use Inline Content (delimited file)**. Then in the **Content** field displayed, enter the data to be written into Salesforce. For example, Talend.

9. Double-click the **tSalesforceOutput** component to open its **Basic settings** view.

10. Select the **tSalesforceConnection** component from the **Connection Component** drop-down list to reuse the connection created by it.

11. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object you want to access. In this example, it is **Account**.

12. Click the [...] button next to **Edit schema** to open the schema dialog box. On the right side of the panel, remove all the columns except the column **Name**. When done, click **OK** to save the changes and close the dialog box.

**Executing the Job**

**Procedure**

1. Press **Ctrl + S** to save the Job.
2. Press **F6** to run the Job. The Studio console gives the URL (in yellow) for OAuth authorization.
3. Copy the URL to the browser’s address bar. The Salesforce.com login page appears.

4. Fill up the username and password and click **Log in to Salesforce**.
   The authorization response is then shown on the browser at the callback host.

5. Now is the time for the Job to continue running.
As shown above, the Job is successfully executed.

6. Go to the Salesforce.com and check the Account object. You can find that the account whose name is "Talend" is inserted.

Related scenario

Upsetting Salesforce data based on external IDs on page 3268
tSalesforceGetDeleted

Collects data deleted during a specific period of time from a Salesforce object.

### tSalesforceGetDeleted Standard properties

These properties are used to configure tSalesforceGetDeleted running in the Standard Job framework.

The Standard tSalesforceGetDeleted component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

#### Basic settings

| **Callback Host** | The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce. This property is available only when the OAuth Implicit Flow type is selected. |
| **Callback Port** | The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce. This property is available only when the OAuth Implicit Flow type is selected. |
| **Token File** | The path to the token file that stores the refresh token used to get the access token without authorization. This property is available only when the OAuth Implicit Flow type is selected. |
| **Module Name** | Click the [...] button next to the field and in the dialog box displayed, select the module that will be used or select the Use custom object check box and specify the module name in the Object Name field. |
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window. Click Sync columns to retrieve the schema from the previous component connected in the Job. |
| **Start Date** | Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data deleted since the specified time. Note that you can collect only the data deleted in the past 30 days. |
| **End Date** | Click the [...] button next to the field and in the calendar dialog box displayed, select the date and time to collect only the data deleted before the specified time. |

### Usage

| **Usage rule** | This component is usually used as a start component of a Job or subJob and it always needs an output link. |

### Recovering deleted data from Salesforce

This scenario describes a two-component Job that collects the account data deleted over the past five days from Salesforce.
Setting up the Job for recovering deleted data from Salesforce

Procedure

1. Create a new Job and add a tSalesforceGetDeleted component and a tLogRow component by typing their names on the design workspace or dropping them from the Palette.
2. Connect the tSalesforceGetDeleted component to the tLogRow component using a Row > Main connection.

Configuring the Job for recovering deleted data from Salesforce

Procedure

1. Double-click the tSalesforceGetDeleted component to open its Basic settings view.

2. In the User Id, Password and Security Key fields, enter the user authentication information required to access Salesforce.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object you want to access. In this example, it is Account. When done, click OK to save the settings and close the dialog box.
4. Click the [...] button next to the **Start Date** field and in the pop-up calendar dialog box, set the value of the start date and time to collect only the data deleted since the specified time. In this example, it is **2016-06-08 00:00:00**.

5. Do the same to set the value of the end date and time in the **End Date** field to collect only the data deleted before the specified time. In this example, it is **2016-06-13 00:00:00**.

6. Double-click the **tLogRow** component to open its **Basic settings** view.
7. Click **Sync columns** to retrieve the schema from the preceding component.
8. In the **Mode** area, select **Vertical (each row is a key/value list)** to display the results in a tabular form on the console.

### Executing the Job to recover deleted data from Salesforce

**Procedure**

1. Press **Ctrl + S** to save your Job.
2. Press **F6** to run your Job.
As shown above, the data deleted during the past five days is collected and displayed in a tabular form on the console.
# tSalesforceGetServerTimestamp

Retrieves the current date of the Salesforce server presented in a timestamp format.

## tSalesforceGetServerTimestamp Standard properties

These properties are used to configure tSalesforceGetServerTimestamp running in the Standard Job framework.

The Standard tSalesforceGetServerTimestamp component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

</tr>
</tbody>
</table>
### Client Secret
The OAuth Consumer Secret, generated when your connected app is created and shown in the connected app detail page in Salesforce. For more information, see Create a Connected App.
This property is available only when the OAuth Implicit Flow type is selected.

### Callback Host
The host value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.
This property is available only when the OAuth Implicit Flow type is selected.

### Callback Port
The port value in the OAuth authentication callback URL that is defined during the creation of a connected app and will be shown in the API (Enable OAuth Settings) area of the connected app detail page in Salesforce.
This property is available only when the OAuth Implicit Flow type is selected.

### Token File
The path to the token file that stores the refresh token used to get the access token without authorization.
This property is available only when the OAuth Implicit Flow type is selected.

### Schema and Edit schema
A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:
- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Salesforce URL</strong></th>
<th>The Webservice URL required to connect to Salesforce.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>API version</strong></td>
<td>The Salesforce API version. This property is available only when the OAuth connection type is selected.</td>
</tr>
<tr>
<td><strong>Use or save the connection session</strong></td>
<td>Select this check box and in the Session directory field displayed, specify the path to the connection session file to be saved or used.</td>
</tr>
</tbody>
</table>
This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided by the component. This way, you do not need to connect to the server to retrieve the session.

When an expired session is detected, if the correct connection information (the user ID, password, and security key) is provided, the component will connect to the server to retrieve the new session information and update the connection session file.

This property is available only when the **Basic** connection type is selected.

</tbody>
</table>
| **Schema and Edit schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to Built-in for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.  
  In this component the schema is related to the Module selected.  
  To retrieve a column from a linked module it is necessary to define the column in a particular manner in the Edit schema view, otherwise the relationship query will not work. The correct syntax is: `NameofCurrentModule_NameofLinkedModule_NameofColumnofInterest`. |
| **Query Mode** | Select the query mode from the drop-down list, either Query or Bulk.  
  - **Query**: the ordinary query. |
<table>
<thead>
<tr>
<th><strong>tSalesforceInput</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bullet</strong></td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Condition</strong></th>
<th>Enter the query used to select the data to be extracted between double quotation marks, for example, &quot;name='Talend'&quot; or &quot;name like '%talend_user%'&quot;.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Manual Query</strong></td>
<td>Select this check box and in the <strong>Full SOQL query string</strong> field displayed, enter the full SOQL (Salesforce Object Query Language) statement used to select the data to be retrieved between double quotation marks. For more information about the SOQL, see Salesforce Object Query Language (SOQL).</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>

</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th><strong>Salesforce URL</strong></th>
<th>The Webservice URL required to connect to Salesforce.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>API version</strong></td>
<td>The Salesforce API version.</td>
</tr>
<tr>
<td><strong>Use or save the connection session</strong></td>
<td>Select this check box and in the <strong>Session directory</strong> field displayed, specify the path to the connection session file to be saved or used.</td>
</tr>
</tbody>
</table>

This session file can be shared by different Jobs to retrieve a connection session as long as the correct user ID is provided.
by the component. This way, you do not need to connect to
the server to retrieve the session.

When an expired session is detected, if the correct
connection information (the user ID, password, and security
key) is provided, the component will connect to the server
to retrieve the new session information and update the
connection session file.

This property is available only when the **Basic** connection
type is selected.

**Need compression**

Select this check box to activate SOAP message
compression, which can result in increased performance
levels.

**Trace HTTP message**

Select this check box to output the HTTP interactions on the
console.

This property is available only when **Bulk** is selected from
the **Query Mode** drop-down list.

**Use HTTP Chunked**

Select this check box to use the HTTP chunked data transfer
mechanism.

This property is available only when **Query** is selected from
the **Query Mode** drop-down list.

**Client Id**

Enter the ID of the real user to differentiate between those
who use the same account and password to access the
Salesforce website.

**Timeout**

Enter the intended number of query timeout in milliseconds
in Salesforce.

**Use Proxy**

Select this check box to use a proxy server, and in the **Host,**
**Port, User Id,** and **Password** fields displayed, specify the
connection parameters of the proxy server.

**Batch Size**

Enter the number of registrations in each processed batch.

This property is available only when **Query** is selected from
the **Query Mode** drop-down list.

**Normalize Delimiter**

Enter the characters, strings or regular expressions used
to normalize the data that is collected by queries set on
different hierarchical Salesforce objects.

This property is available only when **Query** is selected from
the **Query Mode** drop-down list.

**Column Name Delimiter**

Enter the characters, strings or regular expressions used to
separate the name of the parent object from the name of
the child object when you use a query on the hierarchical
relations among the different Salesforce objects.

This property is available only when **Query** is selected from
the **Query Mode** drop-down list.

**Safety Switch**

Clear this check box if the length of any column of the
module to be queried is greater than 100,000 characters.
By default, this check box is selected to prevent excessive
memory usage.

This property is available only when **Bulk** is selected from
the **Query Mode** drop-down list.
Complete Job timeout

The timeout value, in seconds, within which your bulk query Job must be completed. By default, the value is set to 0, which means there is no time limit for your Job to complete.

Salesforce has its own limit for bulk query. If it takes time longer than Salesforce’s timeout limit to process a batch, the batch will be placed in a queue and processed later, and thus it might take too much time for the Job to execute. In this case, you can define the Complete Job timeout value to make your Job end in advance. For more information about Salesforce’s own limit, see Bulk API Limits - Batch processing time.

This property is available only when Bulk is selected from the Query Mode drop-down list.

Enable PK Chunking

Select this check box to enable PK (Primary Key, i.e., the object’s record ID) chunking when extracting large amounts of records or when the query consistently times out. In the Chunk size field displayed, specify the number of records within the ID boundaries for each chunk. For more information, see Use PK Chunking to Extract Large Data Sets from Salesforce.

This property is available only when Bulk is selected from the Query Mode drop-down list.

tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>

</tbody>
</table>

How to set schema for the guess query feature of tSalesforceInput

tSalesforceInput allows you to generate SOQL queries, with both standard objects and fields and custom objects and fields, based on the defined module and schema. This section demonstrates how to set the module and schema when generating an SOQL query.

There are two types of SOQL queries: simple query and relationship query.

Simple query retrieves data from only one object. For more information about how to set the module and schema for generating simple queries, see How to set schema for generating the simple query on page 3258.
Relationship query retrieves data from more than a single type of object, including child-to-parent and parent-to-child relationship queries.

For more information about how to set the module and schema for generating child-to-parent relationship queries, see How to set schema for generating the child-to-parent relationship query on page 3258.

For more information about how to set the module and schema for generating parent-to-child relationship queries, see How to set schema for generating the parent-to-child relationship query on page 3260.

Note that before setting the module name and schema columns for generating the relationship query in the Basic settings view of tSalesforceInput, you need to first identify the relationship type (child-to-parent or parent-to-child) of the query to be generated, because the methods of setting the schema column names for these two kinds of relationship queries are somewhat different. The main difference between the child-to-parent and parent-to-child relationship queries is that the parent-to-child relationship query is specified by using the subquery enclosed in parentheses, while the child-to-parent relationship query is not. For more information about the relationship queries in SOQL and how to identify the relationship queries, see Relationship Queries.

**How to set schema for generating the simple query**

This section demonstrates how to set the module name and schema columns for generating the simple query.

The following two simple query examples will be used for demonstration purpose in the following steps.

- SELECT Id, Name, BillingCity FROM Account, a simple query with standard object and fields, and
- SELECT Name__c, LastName__c FROM Mother__c, a simple query with custom object and fields.

**Procedure**

1. Set the module name with the name of the object specified in the FROM clause, Account and Mother__c for above examples.

2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box and set the column name with the field name.

   For the first example, you need to create three columns Id, Name, and BillingCity for the three fields.

   For the second example, you need to create two columns Name__c and LastName__c for the two fields.

**How to set schema for generating the child-to-parent relationship query**

This section demonstrates how to set the module name and schema columns for generating a child-to-parent relationship query.

The following two child-to-parent relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Account.Name, Account.Owner.Name FROM Contact, a child-to-parent relationship query with standard object and fields, and
• SELECT Id, FirstName__c, MotherOfDaughter__r.FirstName__c FROM Daughter__c, a child-to-parent relationship query with custom object and fields.

   Note that here you must use the relationship name with \_r instead of \_c. For more information, see Understanding Relationship Names, Custom Objects, and Custom Fields.

**Procedure**

1. Set the module name with the name of the object specified in the FROM clause, Contact and Daughter__c in above examples.

2. Create a column for each field in the field list (separated by commas) after SELECT in the schema dialog box.

   For the first example, you need to create three columns for the three fields Name, Account.Name, and Account.Owner.Name.

   For the second example, you need to create three columns for the three fields Id, FirstName__c, and MotherOfDaughter__r.FirstName__c.

3. Set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

   For the first example, the names of the three columns are set to Name, Account_Name, and Account_Owner_Name.

   For the second example, the names of the three columns are set to Id, FirstName__c, and MotherOfDaughter__r_FirstName__c.

4. Set the type of each column.

   The schema for the first example should be set like this:

   ![Schema of tSalesforceInput_1](image)

   And the schema for the second example should be set like this:
Note that the underscore character '_' is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character '_' that goes after '__r' or '__c' will be replaced by the dot character '.' when generating the query. If the underscore character '_' is a part of any custom name in the schema, for example, Contact_custom_field__c, which should be Contact.custom_field__c in the query, you need to replace '_' in the generated query with '.' manually.

**How to set schema for generating the parent-to-child relationship query**

This section demonstrates how to set the module name and schema columns for generating a parent-to-child relationship query.

The following two parent-to-child relationship query examples will be used for demonstration purpose in the following steps.

- SELECT Name, Owner.Name (SELECT CreatedBy.Name FROM Notes) FROM Account, a parent-to-child relationship query with standard object and fields, and
- SELECT LastName__c, (SELECT FirstName__c FROM Daughters__r) FROM Mother__c, a parent-to-child relationship query with custom object and fields.

Note that here you must use the relationship name with __r instead of __c. For more information, see Understanding Relationship Names, Custom Objects, and Custom Fields.

**Procedure**

1. Set the module name with the name of the object specified in the outer query FROM clause, Account and Mother__c in above examples.

2. Create a column for each field (including the fields in subquery) after SELECT in the schema dialog box.

   For the first example, you need to create three columns for the three fields, including two fields Name and Owner.Name after the outer SELECT, and one field CreatedBy.Name after the subquery SELECT.

   For the second example, you need to create two columns for the two fields, including the field LastName__c after the outer SELECT, and the field FirstName__c after the subquery SELECT.
3. For the fields in the outer SELECT clause, which are outside parentheses, set the name of each column with the name of each field and replace all dots in the column name with underscore characters.

   For the first example, the column names for the two fields Name and Owner.Name in the outer SELECT clause are set to Name and Owner_Name.

   For the second example, there is no dot in the field name, so the column name is same as the field name.

4. For the fields in the subquery SELECT, construct the column names using the pattern <$XXX>_records_<$YYY>, where <$XXX> corresponds to the name of the object specified in the subquery FROM clause, and <$YYY> will be the field name with all dots replaced by underscore characters.

   For the first example, the column name for the field CreatedBy.Name in the subquery is set to Notes_records_CreatedBy_Name.

   For the second example, the column name for the field FirstName__c in the subquery is set to Daughters__r_records_FirstName__c.

5. Set the type of each column.

   The schema for the first example should be set like this:

   ![Schema of tSalesforceInput_1](image1)

   And the schema for the second example should be set like this:

   ![Schema of tSalesforceInput_1](image2)
Note that the underscore character '_' is used as a separator between the relationship name and the field name in Talend schema, so only the underscore character '_' that goes after '__r' or '__c' will be replaced by the dot character '.' when generating the query. If the underscore character '_' is a part of any custom name in the schema, for example, Contact_custom_field__c, which should be Contact.custom_field__c in the query, you need to replace '_' in the generated query with '.' manually.

**Related scenario**

*Upserting Salesforce data based on external IDs* on page 3268
tSalesforceOutput

Inserts, updates, upserts, or deletes data in a Salesforce object.

**tSalesforceOutput Standard properties**

These properties are used to configure tSalesforceOutput running in the Standard Job framework.

The Standard tSalesforceOutput component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>

</thead>
<tbody>
<tr>
<td>Extend Insert</td>
<td>Select this check box to transfer the output data in batches. In the <strong>Commit Level</strong> field displayed, specify the number of lines per batch.</td>
</tr>
<tr>
<td>Die on Error</td>
<td>Select the check box to stop the execution of the Job when an error occurs. This check box is cleared by default, meaning to skip the row on error and to complete the process for error-free rows.</td>
</tr>
</tbody>
</table>
| Retrieve Id               | Select this check box to allow Salesforce to return the Salesforce ID for the inserted or updated records. This check box is available only when **INSERT** or **UPSERT** is selected from the **Output Action** drop-down list and the **Extend Insert** check box is cleared. When this check box is selected and the **tSalesforceOutput** component is linked to another component via a **Row > Main** connection, the following column(s) will be added to the schema of the data flow:  
  - **salesforce_id**: the Salesforce ID of the created or updated record.  
  - **salesforce_upsert_status** (only for **UPSERT**): the status of the upsert action to indicate whether the record is created or updated. |
| Ignore Null               | Select this check box to ignore NULL values. This property is available only when **UPDATE** or **UPSERT** is selected from the **Output Action** drop-down list. |
| Log File Name             | Specify the path to the log file that holds all error logs. |
| tStatCatcher Statistics   | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
Global Variables

<table>

Upserting Salesforce data based on external IDs

Here is an example of using Talend components to insert and update Salesforce Contact object data based on the mapping relationship with external IDs of the Account object.

The Job used in this example is composed of the following seven subJobs:

- the first subJob opens a connection to Salesforce,
- the second subJob deletes some Account records based on external IDs,
- the third subJob inserts two Account records with external IDs,
- the fourth subJob inserts three Contact records based on the mapping relationship with the Account object external IDs, and gathers both inserted and erroneous data,
- the fifth subJob updates two inserted Contact records based on the mapping relationship with the Account object external IDs,
- the sixth subJob retrieves the inserted Account records, and
- the seventh subJob retrieves the upserted Contact records.
Creating a Job for upserting Salesforce data based on external IDs

Before you begin

- An external ID custom field `Account_External_ID` has been added for the Account object in your Salesforce, which will be used to map the relationship with the Contact object.
• An external ID custom field `Contact_Talend_ID` has been added for the Contact object in Salesforce, which will be used as the key column for upserting Contact object data.

### Opening a connection to Salesforce

**Procedure**

1. Double-click the `tSalesforceConnection` component to open its **Basic settings** view on the **Component** tab.
2. Select `Basic` from the **Connection type** drop-down list to connect to Salesforce using your Salesforce account username, password, and security token.

   In this example, you connect to Salesforce using the basic connection type. You can also connect to Salesforce using the OAuth JWT (JSON Web Token) Flow type. For more information, see the related description of how to connect to Salesforce using OAuth JWT Flow on Talend Help Center (https://help.talend.com).

3. In the **User Id** field, enter your Salesforce username.
4. Click the `[...]` button next to the **Password** field and in the pop-up dialog box, enter your Salesforce password between double quotation marks.
5. Click the [...] button next to the **Security Token** field and in the pop-up dialog box, enter your Salesforce security token between double quotation marks.

You can use the Salesforce metadata wizard to create a connection to your Salesforce system, save the connection in the Repository, and then reuse the connection configuration defined in the metadata wizard in Salesforce components. For more information, see the related description of centralizing Salesforce metadata.

**Deleting Salesforce Account records based on external ID**

**Procedure**

1. Double-click the first **tSalesforceInput** component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object whose data will be deleted, **Account** in this example. The schema of the Account object will be automatically filled.
4. Click **OK** to save the changes and in the pop-up dialog box, click **Yes** to propagate the schema to the next **tSalesforceOutput** component.
5. Select **Query** from the **Query Mode** drop-down list and specify the condition used to filter data to be deleted. In this example, it is `talendlena__Account_External_ID__c like '%talend%'`.

All Salesforce Account records whose `talendlena__Account_External_ID__c` field contains `talend` will be deleted.

6. Double-click the first **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.
7. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
8. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object whose data will be deleted, **Account** in this example.
9. Select **DELETE** from the **Output Action** drop-down list to perform the delete operation on the Account objects filtered by the first **tSalesforceInput** component.

**Inserting Salesforce Account records with external IDs**

**Procedure**

1. Double-click the second **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.
2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.
3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Account** in this example. The schema of the Account object will be automatically filled.
4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the two columns **Name** and **talendlena__Account_EXTERNAL_ID__c**. Then click the button to copy these two columns to the first **tFixedFlowInput** component. When done, click **OK** to close the dialog box.

5. Select **INSERT** from the **Output Action** drop-down list.

6. Double-click the first **tFixedFlowInput** component to open its **Basic settings** view on the **Component** tab.

7. In the **Mode** area, select **Use Inline Table** and in the table displayed, enter the data to be inserted into the Salesforce Account object. In this example, the following two records will be inserted.

   account_talend;account_talend_exid
   account_talend_doc;account_talend_doc_exid

   You can also select **Use Inline Content**, and then copy and paste the input data into the **Content** field displayed.

**Inserting Salesforce Contact records upon Account external IDs**

**Procedure**

1. Double-click the third **tSalesforceOutput** component to open its **Basic settings** view on the **Component** tab.

2. Select the component that will create the Salesforce connection from the **Connection Component** drop-down list, **tSalesforceConnection_1** in this example.

3. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object into which data will be inserted, **Contact** in this example. The schema of the Contact object will be automatically filled. When done, click **OK** to save the changes and in the pop-up dialog box, click **Yes** to propagate the schema to the next two **tLogRow** components.

4. Click the [...] button next to **Edit schema** and in the pop-up dialog box, remove all schema columns except the three columns **LastName**, **FirstName**, and **talendlena__Contact_Talend_ID__c**. Then add another column **Account_EXTERNAL_ID** of **String** type and copy these four columns to the second **tFixedFlowInput** component. When done, click **OK** to close
the dialog box and in the pop-up dialog box, click **Yes** to propagate the schema to the next two **tLogRow** components.

5. Select **UPSERT** from the **Output Action** drop-down list and **talendlena__Contact_Talend_ID_c** from the **Upsert Key Column** drop-down list displayed.

6. Go to the **Advanced settings** view and in the **Relationship mapping for upsert** table, specify the relationship mapping for the column **AccountExternal_ID** by adding one row and setting the value for each table column. In this example, the column **AccountExternal_ID** is mapped with the external ID field **talendlena__AccountExternal_ID_c** of the Account object, so the value for **Column name of Talend Schema** is **AccountExternal_ID**, the value for **Lookup relationship field name** and **Module name** is **Account**, and the value for **External id name** is **talendlena__AccountExternal_ID_c**.

7. Clear the **Extend Insert** and **Die on Error** check boxes so that erroneous data can be gathered via the **Row > Reject** connection.

8. Double-click the second **tFixedFlowInput** component to open its **Basic settings** view on the **Component** tab.
9. In the Mode area, select Use Inline Table and in the table displayed, enter the data to be inserted into the Salesforce Contact object. In this example, the input data is as follows.

Beckham;David;2018010001;account_talend_exid
Taylor;Swift;2018010002;account_talend_exid

You can also select Use Inline Content, and then copy and paste the input data into the Content field displayed.

10. Double-click the first tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

11. Do the same to configure the second tLogRow component.

**Updating Salesforce Contact records upon Account external IDs**

**Procedure**

1. Double-click the fourth tSalesforceOutput component to open its Basic settings view on the Component tab.

2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.

3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object into which data will be inserted, Contact in this example. The schema of the Contact object will be automatically filled.

4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns Phone, Email, and talendlena__Contact_Talend_ID__c. Then add another column Account_External_ID of String type and copy these four columns to the second tFixedFlowInput component. When done, click OK to close the dialog box.

5. Select UPSERT from the Output Action drop-down list and talendlena__Contact_Talend_ID__c from the Upsert Key Column drop-down list displayed.

6. Go to the Advanced settings view and in the Relationship mapping for upsert table, specify the relationship mapping for the column Account_External_ID by adding one row and setting the value for each table column. In this example, the column Account_External_ID is mapped with the external ID field talendlena__Account_External_ID__c of the Account object, so the value for Column name of Talend Schema is Account_External_ID, the value for Lookup relationship field name and Module name is Account, and the value for External id name is talendlena__Account_External_ID__c.

7. Double-click the third tFixedFlowInput component to open its Basic settings view on the Component tab.
In the Mode area, select Use Inline Table and in the table displayed, enter the data used to update the two records inserted into the Salesforce Contact object. In this example, the updated data is as follows. The phone and email values will be added for both two records and the Account external ID value for the second record is updated to `account_talend_doc_exid`.

You can also select Use Inline Content, and then copy and paste the input data into the Content field displayed.

**Retrieving inserted Salesforce Account records**

**Procedure**

1. Double-click the second tSalesforceInput component to open its Basic settings view on the Component tab.
2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, tSalesforceConnection_1 in this example.
3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object from which data will be retrieved, Account in this example. The schema of the Account object will be automatically filled.
4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the three columns Id, Name, and `talendlena__Account_External_ID__c`. When done, click OK to save the changes and in the pop-up dialog box, click Yes to propagate the schema to the next tLogRow component.
5. Select Query from the Query Mode drop-down list and specify the condition used to filter data to be retrieved. In this example, it is Name like '%talend%'.

   All Salesforce Account records whose Name field contains `talend` will be retrieved.

6. Double-click the third tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

**Retrieving updated Salesforce Contact records using SOQL query**
Procedure

1. Double-click the third `tSalesforceInput` component to open its Basic settings view on the Component tab.

2. Select the component that will create the Salesforce connection from the Connection Component drop-down list, `tSalesforceConnection_1` in this example.

3. Click the [...] button next to the Module Name field and in the pop-up dialog box, select the object from which data will be retrieved, Contact in this example. The schema of the Contact object will be automatically filled.

4. Click the [...] button next to Edit schema and in the pop-up dialog box, remove all schema columns except the four columns `Name`, `Phone`, `Email`, and `talendlena__Contact_Talend_ID__c`.

5. Add another two columns to retrieve name and external ID of the linked Account object, `Contact_Account_Name` and `Contact_Account_talendlena__Account_External_ID__c` in this example.

To retrieve data of a linked object column, it is necessary to define the name of the column in a particular manner in the schema editor. The correct syntax is `NameOfCurrentObject_NameOfLinkedObject_NameOfColumnOfInterest`. If this syntax is not respected, data from the linked object will not be returned. For more information about how to set schema for the relationship query, see How to set schema for the guess query feature of `tSalesforceInput` on page 3257.

6. Click OK to save the changes. In the pop-up dialog box, click Yes to propagate the schema to the next `tLogRow` component.

7. Select Query from the Query Mode drop-down list.

8. Select the Manual Query check box and click the Guess query button to generate the SOQL query based on the defined module name and schema columns. The generated SOQL query will look like below.

   ```sql
   SELECT Name, Phone, Email, talendlena__Contact_Talend_ID__c, Contact.Account.Name, Contact_Account_talendlena__Account_External_ID__c FROM Contact
   ```

9. In the generated SOQL query string, replace each underscore character after the object name in the column name `Contact_Account_talendlena__Account_External_ID__c` with a dot character. Then add the WHERE condition clause used to filter data to be retrieved at the end of the generated SOQL query. In this example, it is `talendlena__Contact_Talend_ID__c`.
D\_c \text{ like } '201801\%' \text{ and all Salesforce Contact records whose talendlena\_Contact_Talend\_ID\_c field begins with } 201801 \text{ will be retrieved. The updated SOQL query will look like below.}

```
SELECT Name, Phone, Email, talendlena\_Contact_Talend\_ID\_c, Contact.Account.Name, Contact.Account.talendlena\_Account\_External\_ID\_c FROM Contact
WHERE talendlena\_Contact_Talend\_ID\_c like '201801\%'
```

10. Double-click the fourth tLogRow component and on its Basic settings view, select Table in the Mode area to display the result in a table.

### Executing the Job to upsert Salesforce data based on external ID

**Procedure**

1. Press Ctrl + S to save your Job.
2. Press F6 to execute your Job.

As shown above, two Account records account_talend and account_talend_doc are successfully inserted, two Contact records Beckham David and Taylor Swift are successfully inserted and updated based on the mapping relationship with the external IDs in the Account object, and another Contact record missing the value for the required field LastName is not inserted.

You can also go to the Salesforce website to double-check the Job execution result.
tSalesforceOutputBulk

Generates the file to be processed by the tSalesforceBulkExec component for bulk processing.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

**tSalesforceOutputBulk Standard properties**

These properties are used to configure tSalesforceOutputBulk running in the Standard Job framework.

The Standard tSalesforceOutputBulk component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
• **View schema**: choose this option to view the schema only.  
• **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
• **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
Click **Sync columns** to retrieve the schema from the previous component connected in the Job. |
<table>
<thead>
<tr>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Bulk File Path</strong></td>
<td>Specify the path to the file to be generated.</td>
</tr>
<tr>
<td><strong>Append</strong></td>
<td>Select this check box to append new data at the end of the file if it already exists, instead of overwriting the existing data.</td>
</tr>
<tr>
<td><strong>Ignore Null</strong></td>
<td>Select this check box to ignore NULL values.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| Relationship mapping for upsert | Click the [+] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module. |
• **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.

• **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view of the **tSalesforceBulkExec** component and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.

• **Module name**: the name of the lookup module.

• **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search **polymorphic** at [http://www.salesforce.com/us/developer/docs/api_asynch/](http://www.salesforce.com/us/developer/docs/api_asynch/).

• **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

### Usage

| Usage rule | This component is more commonly used with the **tSalesforceBulkExec** component. Used together, they gain performance while feeding or modifying information in Salesforce.com. |

### Related scenario

No scenario is available for this component yet.
tSalesforceOutputBulkExec

Bulk-loads data in a given file into a Salesforce object.

The tSalesforceOutputBulk and tSalesforceBulkExec components are used together in a two step process. In the first step, an output file is generated. In the second step, this file is used to feed the Salesforce database. These two steps are fused together in the tSalesforceOutputBulkExec component. The advantage of using two separate steps is that the data can be transformed before it is loaded into Salesforce.

tSalesforceOutputBulkExec Standard properties

These properties are used to configure tSalesforceOutputBulkExec running in the Standard Job framework.

The Standard tSalesforceOutputBulkExec component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

</table>

| **Bulk API V2** | Select this checkbox to create a Bulk API V2 job, and then select a type of field delimiter from the **Column Delimiter** drop-down list and a way of line ending from the **Line Ending** drop-down list respectively for CSV data. Compared with Bulk API V1, Bulk API v2 simplifies the way of processing data. |
| Relationship mapping for upsert | Click the [+] button to add lines as needed and specify the external ID fields in the input flow, the lookup relationship fields in the upsert module, the lookup module as well as the external ID fields in the lookup module.  
- **Column name of Talend Schema**: the name of the external ID field in the input flow. It refers to the fields in the schema of the preceding component. Such columns are intended to match against the external ID fields specified in the **External id name** column, which are the fields of the lookup module specified in the **Module name** column.  
- **Lookup relationship field name**: the name of the lookup relationship field. It refers to the lookup relationship fields of the module specified in the **Module Name** field in the **Basic settings** view and is intended to establish relationship with the lookup module specified in the **Module name** column in this table. For how to define the lookup relationship fields and how to provide their correct names in the **Lookup relationship field name** field, go to the Salesforce website and launch the Salesforce Data Loader application for proper actions and information.  
- **Module name**: the name of the lookup module.  
- **Polymorphic**: select this check box when and only when polymorphic fields are used for relationship mapping. You will get an error if you keep this check box cleared for a polymorphic field or select it for a field that is not polymorphic. For more information about the polymorphic fields, search **polymorphic** at [http://www.salesforce.com/us/developer/docs/api_asynch/](http://www.salesforce.com/us/developer/docs/api_asynch/).  
- **External id name**: the name of the external ID field in the lookup module specified in the **Module name** column.  
This property is available only when **UPSERT** is selected from the **Output Action** drop-down list. |

| Concurrency Mode | Select the concurrency mode for the job.  
- **Parallel**: process batches in parallel mode.  
- **Serial**: process batches in serial mode. |

| Rows to Commit | Specify the number of lines per data batch to be processed. |

| Bytes to Commit | Specify the number of bytes per data batch to be processed. |

| Wait Time Check Batch State | Specify the wait time (in milliseconds) for checking whether the batches in a Job have been processed until all batches are finally processed. |

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

Inserting bulk data into Salesforce

This scenario describes a four-component Job that bulk-loads data in a file into Salesforce, performs the intended action on the data, and ends up with displaying the Job execution results on the console.

The content of the input file SalesforceAccount.txt used in this example is as follows:

Name;ParentId;Phone;Fax
Burlington Textiles Corp of America;;(336) 222-7000;(336) 222-8000
Dickenson plc;; (785) 241-6200;(785) 241-6201
GenePoint;;(650) 867-3450;(650) 867-9895
Edge Communications;talend;(512) 757-6000;(512) 757-9000
Grand Hotels & Resorts Ltd;talend;(312) 596-1000;(312) 596-1500

Setting up the Job for inserting bulk data into Salesforce

Procedure

1. Create a new Job and add a tFileInputDelimited component, a tSalesforceOutputBulkExec component, and two tLogRow components by typing their names on the design workspace or dropping them from the Palette.
2. Link the tFileInputDelimited component to the tSalesforceOutputBulkExec component using a Row > Main connection.
3. Link the tSalesforceOutputBulkExec component to the first tLogRow component using a Row > Main connection.
4. Link the tSalesforceOutputBulkExec component to the second tLogRow component using a Row > Reject connection.
Configuring the Job for inserting bulk data into Salesforce

Procedure

1. Double-click the **tFileInputDelimited** component to open its **Basic settings** view.

2. In the **File name/Stream** field, browse to or enter the path to the input data file. In this example, it is `D:/SalesforceAccount.txt`.

3. Click the `...` button next to **Edit schema** and in the pop-up schema dialog box, define the schema by adding four columns `Name`, `ParentId`, `Phone` and `Fax` of String type. When done, click **OK** to save the changes and close the dialog box.

4. Double-click the **tSalesforceOutputBulkExec** component to open its **Basic settings** view.
5. In the **User Id**, **Password** and **Security Key** fields, enter the user authentication information required to access Salesforce.

6. Click the [...] button next to the **Module Name** field and in the pop-up dialog box, select the object you want to access. In this example, it is **Account**.

7. In the **Bulk File Path** field, browse to or enter the path to the CSV file that stores the data for bulk processing. The bulk file to be processed must be in csv format.

8. Double-click the first **tLogRow** component to open its **Basic settings** view.

9. In the **Mode** area, select **Table (print values in cells of a table)** for better readability of the results.

10. Do the same to configure the second **tLogRow** component.

### Executing the Job to insert bulk data into Salesforce

**Procedure**

1. Press **Ctrl + S** to save the Job.

2. Press **F6** to execute the Job.

   On the console of the **Run** view, you can check the execution result.
In the tLogRow_1 table, you can read the data inserted into Salesforce.

In the tLogRow_2 table, you can read the rejected data due to the incompatibility with the Account objects you have accessed.

Note that if you want to transform the input data before loading them into Salesforce, you need to use tSalesforceOutputBulk and tSalesforceBulkExec in cooperation to achieve this purpose.
## tSalesforceEinsteinBulkExec

Loads data into Salesforce Analytics Cloud from a local file.

### tSalesforceEinsteinBulkExec Standard properties

These properties are used to configure tSalesforceEinsteinBulkExec running in the Standard Job framework.

The Standard tSalesforceEinsteinBulkExec component belongs to the Business and the Cloud families. The component in this framework is available in all Talend products.

#### Basic settings

<table>
<thead>
<tr>
<th>Property Type</th>
<th>Either <strong>Built-In</strong> or <strong>Repository</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Built-In</strong></td>
<td>No property data stored centrally.</td>
</tr>
<tr>
<td><strong>Repository</strong></td>
<td>Select the repository file in which the properties are stored. The connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

**Use an existing connection**

Select this check box and in the **Component List** click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, **Component List** presents only the connection components in the same Job level.

**User Name** and **Password**

Enter the Web service authentication details.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

**End Point**

Enter the WebService URL required to connect to Salesforce. For example, `https://login.salesforce.com/services/Soap/u/37.0`. Note that the version in the URL should be 32.0 or later.

**Schema** and **Edit schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

- For the fields of numeric type (for example, byte, short, int, long, float, double, and BigDecimal), their length and precision values need to be specified. The default length and precision values are **10** and **2**, and you can also specify their custom values in the schema editor.
- For the fields of date type, you need to specify the format of the date in the schema editor. For more information about the supported date format, see [Analytics Cloud External Data Format Reference](#).
The **Schema** list and the **Editor schema** button disappear if the **Custom JSON Metadata** check box is selected.

<table>
<thead>
<tr>
<th>Built-In: You create and store the schema locally for this component only.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.</strong></td>
</tr>
</tbody>
</table>

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema:** choose this option to view the schema only.
- **Change to built-in property:** choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection:** choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

**Operation**

Select an operation to perform on the dataset:

- **Append:** Append all data to the dataset. Create a dataset if it does not exist.
- **Upsert:** Insert or update rows in the dataset. Create a dataset if it does not exist.
- **Overwrite:** Create a new dataset with the given data, and replace dataset if it already exists.
- **Delete:** Delete the rows from the dataset.

**Note:**

- A metadata JSON file is required for the **Append**, **Upsert**, and **Delete** operations.
- The data and metadata for the **Append** and **Upsert** operations must match the dataset on which the operation is happening. All columns, dimensions, and measures must match exactly.
- The **Append** operation is not allowed if you specify any column as the primary key.
- You must specify one (and only one) column as the primary key on which the **Upsert** or **Delete** operation is based. You can do that by clicking **Edit schema** and selecting the check box next to the column you want to set as the primary key.
- The metadata for the **Delete** operation must be a subset of the dataset columns.

<table>
<thead>
<tr>
<th>Name</th>
<th>Type in the name of the dataset into which the data will be loaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>CSV File</td>
<td>Specify the path to the local CSV file to be loaded.</td>
</tr>
</tbody>
</table>
## Advanced settings

<td>Repository: Select the repository file in which the properties are stored. The connection fields that follow are completed automatically using the data retrieved.</td>
</tr>
</tbody>
</table>

Use an existing connection

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

Note that when a Job contains the parent Job and the child Job, Component List presents only the connection components in the same Job level.

User Name and Password

Enter the Web service authentication details.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

End Point

Enter the WebService URL required to connect to Salesforce. For example, https://login.salesforce.com/services/Soap/u/37.0. Note that the version in the URL should be 32.0 or later.

Schema and Edit schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- For the fields of numeric type (for example, byte, short, int, long, float, double, and BigDecimal), their length and precision values need to be specified. The default length and precision values are 10 and 2, and you can also specify their custom values in the schema editor.
- For the fields of date type, you need to specify the format of the date in the schema editor. For more
Information about the supported date format, see [Analytics Cloud External Data Format Reference](#).

The **Schema** list and the **Editor schema** button disappear if the **Custom JSON Metadata** check box is selected.

| **Built-In** | You create and store the schema locally for this component only. |
| **Repository** | You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs. |

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Click **Sync columns** to retrieve the schema from the previous component connected in the Job.

**Operation**

Select an operation to perform on the dataset:

- **Append**: Append all data to the dataset. Create a dataset if it does not exist.
- **Upsert**: Insert or update rows in the dataset. Create a dataset if it does not exist.
- **Overwrite**: Create a new dataset with the given data, and replace dataset if it already exists.
- **Delete**: Delete the rows from the dataset.

**Note**:

- A metadata JSON file is required for the **Append**, **Upsert**, and **Delete** operations.
- The data and metadata for the **Append** and **Upsert** operations must match the dataset on which the operation is happening. All columns, dimensions, and measures must match exactly.
- The **Append** operation is not allowed if you specify any column as the primary key.
- You must specify one (and only one) column as the primary key on which the **Upsert** or **Delete** operation is based. You can do that by clicking **Edit schema** and selecting the check box next to the column you want to set as the primary key.
- The metadata for the **Delete** operation must be a subset of the dataset columns.

**Name**

Type in the name of the dataset into which the data will be loaded.

</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</th>
</tr>
</thead>
</table>
Usage

Usage rule

| This component handles flows of data therefore it requires input and output components. |

Filtering rows and groups of rows

This scenario describes a three-component Job. A **tRowGenerator** is used to create random entries which are directly sent to a **tSampleRow** where they will be filtered according to a defined range. In this scenario, we suppose the input flow contains names of salespersons along with their respective number of sold products and their years of presence in the enterprise. The result of the filtering operation is displayed on the **Run** console.

Dropping and linking the components

**Procedure**

1. Drop the following components from the Palette onto the design workspace: **tRowGenerator**, **tSampleRow**, and **tLogRow**.
2. Connect the three components using **Row > Main** links.

Results

```
<table>
<thead>
<tr>
<th>row1 (Main)</th>
<th>row2 (Main)</th>
</tr>
</thead>
<tbody>
<tr>
<td>tRowGenerator_1</td>
<td>tSampleRow_1</td>
</tr>
<tr>
<td>tLogRow_1</td>
<td></td>
</tr>
</tbody>
</table>
```

Configuring the components

**Procedure**

1. In the design workspace, select **tRowgenerator**, and click the **Component** tab to define the basic settings for **tRowGenerator**.
2. Click the [...] button next to **Edit Schema** to define the data you want to use as input. In this scenario, the schema is made of five columns.
3. In the Basic settings view, click RowGenerator Editor to define the data to be generated.

4. In the RowGenerator Editor, specify the number of rows to be generated in the Number of Rows for RowGenerator field and click OK. The RowGenerator Editor closes.

5. In the design workspace, select tSampleRow and click the Component tab to define the basic settings for tSampleRow.

6. In the Basic settings view, set the Schema to Built-In and click Sync columns to retrieve the schema from the tRowGenerator component.

7. In the Range panel, set the filter to select your rows using the correct syntax as explained. In this scenario, we want to select the first and fifth lines along with the group of lines between 9 and 12.

8. In the design workspace, select tLogRow and click the Component tab to define its basic settings. For more information about tLogRow, see tLogRow on page 1977.
Saving and executing the Job

Procedure

1. Press **Ctrl+S** to save your Job.
2. Press **F6**, or click **Run** on the **Run** tab to execute the Job.

Results

```
Starting job sample_Row at 11:16 20/08/2008.

<table>
<thead>
<tr>

<tr>
<td>Close Connection</td>
<td>This check box is selected by default. It allows you to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Warning:**
If you want to use a Row > Main connection to link tSAPHanaCommit to your Job, your data will be committed row by row. In this case, do not select the Close connection check box or your connection will be closed before the end of your first row commit.

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSAPHana* components, especially with the tSAPHanaConnection and tSAPHanaRollback components. Use this component if the Auto Commit option of the tSAPHanaConnection component is cleared. |

3304
Related scenario

For a related scenario, see Inserting data in mother/daughter tables on page 2426.
tSAPHanaConnection

Establishes a SAP HANA connection to be reused by other SAP HANA components in your Job.
tSAPHanaConnection opens a connection to the database for a current transaction.

**tSAPHanaConnection Standard properties**

These properties are used to configure tSAPHanaConnection running in the Standard Job framework.
The Standard tSAPHanaConnection component belongs to the Databases and the ELT families.
The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Host</td>
<td>Database server IP address.</td>
</tr>
<tr>
<td>Port</td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the database schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional connection properties in the database connection you are creating.</td>
</tr>
</tbody>
</table>

### Advanced settings

**Auto Commit**

Select this check box to commit any changes to the database automatically upon the transaction.

With this check box selected, you cannot use the corresponding commit component to commit changes to the database; likewise, when using the corresponding commit component, this check box has to be cleared. By default, the auto commit function is disabled and changes must be committed explicitly using the corresponding commit component.

Note that the auto commit function commits each SQL statement as a single transaction immediately after the statement is executed while the commit component does not commit only until all of the statements are executed. For this reason, if you need more room to manage your
tSAPHanaConnection

transactions in a Job, it is recommended to use the commit component.

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Usage**

| **Usage rule** | This component is more commonly used with other tSAPHana* components, especially with the tSAPHanaCommit and tSAPHanaRollback components. |
| **Support** | tSAPHanaConnection should be used to interact with the ERP part of SAP, including S4/HANA. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
tSAPHanaInput

Executes a database query with a defined command which must correspond to the schema definition. tSAPHanaInput reads a database and extracts fields based on a query. Then it passes on rows to the next component via a **Main** row link.

**tSAPHanaInput Standard properties**

These properties are used to configure tSAPHanaInput running in the Standard Job framework.

The Standard tSAPHanaInput component belongs to the Databases family.

The component in this framework is available in all **Talend products with Big Data** and in **Talend Data Fabric**.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see **Dynamic database components on page 595**.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the <strong>Component List</strong> click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the **Basic settings** view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see **Talend Studio User Guide**.

<table>
<thead>
<tr>
<th>Host</th>
<th>Database server IP address.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Port</td>
<td>Listening port number of database server.</td>
</tr>
<tr>
<td>Schema</td>
<td>Name of the database schema.</td>
</tr>
<tr>
<td>Username and Password</td>
<td>Database authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-in**: The schema is created and stored locally for this component only. For more information, see *Talend Studio User Guide*.

**Repository**: The schema already exists and is stored in the Repository, hence can be reused. For more information, see *Talend Studio User Guide*.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Table Name

Name of the table to be written. Note that only one table can be written at a time.

### Query Type

Either **Built-in** or **Repository**.

**Built-in**: Fill in manually the query statement or build it graphically using SQLBuilder.

**Repository**: Select the relevant query stored in the Repository. The Query field gets accordingly filled in.

### Guess Query

Click the **Guess Query** button to generate the query which corresponds to your table schema in the **Query** field.

### Guess schema

Click the **Guess schema** button to retrieve the table schema.

### Query

Enter your database query paying particularly attention to properly sequence the fields in order to match the schema definition.

### Advanced settings

### Additional JDBC Parameters

Specify additional connection properties in the database connection you are creating. This option is not available if you have selected **Use an existing connection** check box in the **Basic settings**.
### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
<th>NB_LINE: the number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td>QUERY: the query statement being processed. This is a Flow variable and it returns a string.</td>
</tr>
<tr>
<td></td>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
<tr>
<td></td>
<td>A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
<tr>
<td></td>
<td>To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.</td>
</tr>
<tr>
<td></td>
<td>For further information about variables, see Talend Studio User Guide.</td>
</tr>
</tbody>
</table>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is standalone as it includes the SAP HANA engine. This is a startable component that can initiate a data flow processing.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Support</td>
<td>tSAPHanalnput should be used to interact with the ERP part of SAP, including S4/HANA.</td>
</tr>
<tr>
<td>Dynamic settings</td>
<td>Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.</td>
</tr>
<tr>
<td></td>
<td>The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the</td>
</tr>
</tbody>
</table>
Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenarios

No scenario is available for the Standard version of this component yet.
tSAPHanaOutput

Executes the action defined on the table and/or on the data contained in the table, based on the flow incoming from the preceding component in the Job.

tSAPHanaOutput writes, updates, makes changes or suppresses entries in a SAP HANA database.

**tSAPHanaOutput Standard properties**

These properties are used to configure tSAPHanaOutput running in the Standard Job framework. The Standard tSAPHanaOutput component belongs to the Databases family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Database</td>
<td>Select a type of database from the list and click Apply.</td>
</tr>
<tr>
<td>Use an existing connection</td>
<td>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</td>
</tr>
</tbody>
</table>

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>Username and Password</td>
<td>Database authentication data. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the</td>
</tr>
</tbody>
</table>
password between double quotes and click **OK** to save the settings.

<table>
<thead>
<tr>
<th><strong>Table</strong></th>
<th>Name of the table to be written. Note that only one table can be written at a time.</th>
</tr>
</thead>
</table>

<table>
<thead>
<tr>
<th><strong>Action on table</strong></th>
<th>On the table defined, you can perform one of the following operations:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>None</strong></td>
<td>No operation is carried out.</td>
</tr>
<tr>
<td><strong>Drop and create table</strong></td>
<td>The table is removed and created again.</td>
</tr>
<tr>
<td><strong>Create table</strong></td>
<td>The table does not exist and gets created.</td>
</tr>
<tr>
<td><strong>Create table if not exists</strong></td>
<td>The table is created if it does not exist.</td>
</tr>
<tr>
<td><strong>Drop table if exists and create</strong></td>
<td>The table is removed if it already exists and created again.</td>
</tr>
<tr>
<td><strong>Clear table</strong></td>
<td>The table content is deleted.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Type of table storage</strong></th>
<th>This option is only available if you create (with or without drop) the database table. This option allows you to define the way the data is stored in the table. The following types of table storage organization are available:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Row</strong></td>
<td>Data is stored in rows. It is preferable to use this table type if the majority of table access involves selecting a few records, with all attributes selected.</td>
</tr>
<tr>
<td><strong>Column</strong></td>
<td>Data is stored in columns. It is preferable to use this table type if the majority of table access will be through a large number of tuples, with only a few selected attributes.</td>
</tr>
<tr>
<td><strong>History column</strong></td>
<td>Creates a table with a particular transaction session type called HISTORY. Tables with session type HISTORY support time travel queries. For more information on HISTORY and time travel queries, see <a href="http://help.sap.com/saphelp_hanaplatform/helpdata/en/20/d56cd075191014b7ea9e4e77477aae/content.htm">http://help.sap.com/saphelp_hanaplatform/helpdata/en/20/d56cd075191014b7ea9e4e77477aae/content.htm</a>.</td>
</tr>
<tr>
<td><strong>Global temporary</strong></td>
<td>The table definition and data can be seen by any user and any connection during the current session. The table is truncated at the end of the session.</td>
</tr>
<tr>
<td><strong>Local temporary</strong></td>
<td>The table definition and data can only be seen by the user who created the table during the current session. The table is truncated at the end of the session.</td>
</tr>
</tbody>
</table>

<table>
<thead>
<tr>
<th><strong>Action on data</strong></th>
<th>On the data of the table defined, you can perform:</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Insert</strong></td>
<td>Add new entries to the table. If duplicates are found, the Job stops.</td>
</tr>
<tr>
<td><strong>Update</strong></td>
<td>Make changes to existing entries</td>
</tr>
<tr>
<td><strong>Insert or update</strong></td>
<td>Insert a new record. If the record with the given reference already exists, an update would be made.</td>
</tr>
<tr>
<td><strong>Update or insert</strong></td>
<td>Update the record with the given reference. If the record does not exist, a new record would be inserted.</td>
</tr>
<tr>
<td><strong>Delete</strong></td>
<td>Remove entries corresponding to the input flow.</td>
</tr>
</tbody>
</table>
Note that it is necessary to specify at least one column as a primary key on which the **Update** and **Delete** operations are based. You can do that by clicking **Edit Schema** and selecting the check box(es) next to the column(s) you want to set as primary key(s). For an advanced use, see **Use filed options** in the **Advanced settings** view.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word **line** when naming the fields.

**Built-In**: You create and store the schema locally for this component only.

**Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

When the schema to be reused has default values that are integers or functions, ensure that these default values are not enclosed within quotation marks. If they are, you must remove the quotation marks manually.

You can find more details about how to verify default values in retrieved schema in Talend Help Center (https://help.talend.com).

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

### Die on error

This check box is cleared by default. This means that **Die on error** skips the row when an error is encountered and completes the process for rows without errors.

### Advanced settings

#### Use alternate schema

Select this option to use a schema other than the one specified by the component that establishes the database connection (that is, the component selected from the **Component list** drop-down list in **Basic settings** view).

After selecting this option, provide the name of the desired schema in the **Schema** field.

This option is available when **Use an existing connection** is selected in **Basic settings** view.

#### Additional JDBC Parameters

Specify additional connection properties in the database connection you are creating. This option is not available if
you have selected **Use an existing connection** check box in the **Basic settings**.

<table>
<thead>
<tr>
<th>Commit every</th>
<th>Enter the number of rows to be completed before committing batches of rows together into the database. This option ensures transaction quality (but not rollback) and, above all, better performance at execution.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional Columns</td>
<td>This option is not available if you create (with or without drop) the database table. This option allows you to call SQL functions to perform actions on columns, which are not insert, nor update or delete actions, or any other action that requires particular preprocessing.</td>
</tr>
<tr>
<td>Name:</td>
<td>Type in the name of the schema column to be altered or inserted as new column</td>
</tr>
<tr>
<td><strong>SQL expression:</strong></td>
<td>Type in the SQL statement to be executed in order to alter or insert the relevant column data.</td>
</tr>
<tr>
<td><strong>Position:</strong></td>
<td>Select <strong>Before</strong>, <strong>Replace</strong> or <strong>After</strong> following the action to be performed on the reference column.</td>
</tr>
<tr>
<td>Reference column:</td>
<td>Type in a column of reference that tSAPHanaOutput can use to locate or replace the new column or the column to be modified.</td>
</tr>
<tr>
<td>Use field options</td>
<td>Select this check box to customize a request, especially when there is double action on data. In that table, you can define: <strong>Key in update</strong>: define the primary key to use in an update operation. <strong>Key in delete</strong>: define the primary key to use in a delete operation. <strong>Updatable</strong>: define the column(s) to update. <strong>Insertable</strong>: define the column(s) to insert.</td>
</tr>
<tr>
<td>Enable debug mode</td>
<td>Select this check box to display each step during processing entries in a database.</td>
</tr>
<tr>
<td>Support null in “SQL WHERE” statement</td>
<td>Select this check box to validate null in “SQL WHERE” statement.</td>
</tr>
<tr>
<td>Use Batch Size</td>
<td>When selected, enables you to define the number of lines in each processed batch. This option is available only when you do not <strong>Use an existing connection</strong> in <strong>Basic settings</strong>.</td>
</tr>
<tr>
<td>tStatCatcher Statistics</td>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

**Global Variables**

<table>
<thead>
<tr>
<th>Global Variables</th>
<th><strong>NB_LINE</strong>: the number of rows processed. This is an After variable and it returns an integer. <strong>NB_LINE_UPDATED</strong>: the number of rows updated. This is an After variable and it returns an integer.</th>
</tr>
</thead>
</table>
### tSAPHanaOutput

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE_INSERTED</strong></td>
<td>the number of rows inserted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_DELETED</strong></td>
<td>the number of rows deleted. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>NB_LINE_REJECTED</strong></td>
<td>the number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td><strong>QUERY</strong></td>
<td>the query statement processed. This is an After variable and it returns a string.</td>
</tr>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.

For further information about variables, see [Talend Studio User Guide](#).

### Usage

#### Usage rule

This component must be connected to an Input component. It allows you to carry out actions on a table or on the data of a table in an SAP HANA database. It also allows you to create reject flows using a Row > Reject link to filter erroneous data.

#### Support

tSAPHanaOutput should be used to interact with the ERP part of SAP, including S4/HANA.

#### Dynamic settings

Click the [*] button to add a row in the table and fill the **Code** field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The **Dynamic settings** table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the **Component List** box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.
Related scenarios

No scenario is available for the Standard version of this component yet.
**tSAPHanaRollback**

Avoids to commit part of a transaction involuntarily. tSAPHanaRollback cancels the transaction in the connected database.

**tSAPHanaRollback Standard properties**

These properties are used to configure tSAPHanaRollback running in the Standard Job framework. The Standard tSAPHanaRollback component belongs to the Databases family. The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Component list</td>
<td>Select the tSAPHanaConnection component in the list if more than one connection is planned for the current Job.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Clear this check box to continue to use the selected connection once the component has performed its task.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

**Usage**

| Usage rule | This component is more commonly used with other tSAPHana* components, especially with the tSAPHanaConnection and tSAPHanaCommit components. |
| Support | tSAPHanaRollback should be used to interact with the ERP part of SAP, including S4/HANA. |

**Related scenarios**

No scenario is available for the Standard version of this component yet.
**tSAPHanaRow**

Acts on the actual database structure or on the data (although without handling data).

tSAPHanaRow is the specific component for this database query. It executes the SQL query stated onto the specified database. The row suffix means the component implements a flow in the Job design although it does not provide output.

The SQLBuilder tool helps you write easily your SQL statements.

**tSAPHanaRow Standard properties**

These properties are used to configure tSAPHanaRow running in the Standard Job framework.

The Standard tSAPHanaRow component belongs to the Databases family.

The component in this framework is available in all Talend products with Big Data and in Talend Data Fabric.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
</table>

**Use an existing connection**

Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.

**Note:** When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:

1. In the parent level, register the database connection to be shared in the Basic settings view of the connection component which creates that very database connection.
2. In the child level, use a dedicated connection component to read that registered database connection.

For an example about how to share a database connection across Job levels, see Talend Studio User Guide.

**Property type**

Either Built-in or Repository.

**Built-in:** No property data stored centrally.

**Repository:** Select the repository file in which the properties are stored. The fields that follow are completed automatically using the data retrieved.
<table>
<thead>
<tr>
<th><strong>Host</strong></th>
<th>Database server IP address.</th>
</tr>

</tbody>
</table>
| **ERROR_MESSAGE** | the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
  A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component offers the flexibility of the database query and covers all possible SQL queries.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Support</strong></td>
<td>tSAPHanaRow should be used to interact with the ERP part of SAP, including S4/HANA.</td>
</tr>
</tbody>
</table>

**Related scenarios**

No scenario is available for the Standard version of this component yet.
Exporting data using tSAPHanaUnload

tSAPHanaUnload lets you export data from an SAP HANA database, which you can import to a third-party storage such as Amazon S3.

This sample scenario includes a Talend Job that shows you how you can use tSAPHanaUnload when exporting massive data all at once.

Let’s imagine you have a table in the SAP HANA database that contains the information of your clients. This information includes their names, their companies, their email addresses, and other important data needed to transact business. Now, you want to export these data and store them in an external storage system. It may be possible to directly export data from the SAP HANA database, but we are talking about a huge amount of client information. This is where tSAPHanaUnload becomes useful.

Prerequisite

• Ensure that you have access to both the SAP HANA database engine and the unload directory

Creating the SAP HANA database connection

Specify your SAP HANA database in Talend Studio.

Procedure

1. Select Metadata > DB Connections.
2. Right-click and select Create connection.
3. Fill in the Name, Purpose, and Description fields.
4. Click Next.
5. Select SAPHana from the DB Type dropdown list.
6. Provide the following information:
   • Login
   • Password
   • Server
   • Port
   • Schema
   • Additional Parameters

Note: Once you enter the Port number, the String of Connection automatically retrieves the corresponding value and displays it in the field.
Creating and running the Job

Add components in to your design workspace and configure these before running the Job.

Procedure

1. Drag-and-drop the SAP HANA database connection you previously created into the design workspace.
2. Add the tSAPHanaUnload component.
3. Connect the components using the Trigger > OnSubjobOk.
   The following image displays the sample Job:

4. Select tSAPHanaUnload and view the Basic settings tab.
   a) Mark the Use an existing connection checkbox.
   b) Select tDBConnection_1-SAPHANA option from the dropdown list.
   c) Enter the name of the SAP HANA database table that you wish to export in the Table field.
   d) Add the target location where you want to store the exported data in the Export location on the SAP HANA host field. This refers to a directory in your SAP HANA database local machine.
5. Run the Job.

Results

All the data from the specified SAP HANA database table are exported and stored locally in the unload directory of your SAP HANA database machine. Note that you can find the exported data in a subdirectory of your target location.

tSAPHanaUnload exports and creates several files in the subdirectory, including the metadata of the SAP HANA table, the information about the extracted data, the information about the SAP HANA system, the commands for file import into SAP HANA, and so on. Be sure to look into the data.csv, which contains the data you need.

You can further use the exported data and send these to a third-party storage system of your choice.
tSchemaComplianceCheck

Ensures the data quality of any source data against a reference data source.

tSchemaComplianceCheck validates all input rows against a reference schema or check types, nullability, length of rows against reference values. The validation can be carried out in full or partly.
tSCPClose

Closes a connection to an SCP protocol.
tSCPClose closes a connection to a fully encrypted channel.

**tSCPClose Standard properties**

These properties are used to configure tSCPClose running in the Standard Job framework.
The Standard tSCPClose component belongs to the Internet family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

<td>the execution result of the component. This is an After variable and it returns a string. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.</td>
</tr>
</tbody>
</table>
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule          | This component is typically used as a single-component subJob but can also be used with other components. |

Related scenarios

No scenario is available for the Standard version of this component yet.
tSCPFileExists

Verifies the existence of a file on the defined SCP server.
tSCPFileExists checks, over a fully encrypted channel, if a file exists on a remote host.

**tSCPFileExists Standard properties**

These properties are used to configure tSCPFileExists running in the Standard Job framework.
The Standard tSCPFileExists component belongs to the Internet family.
The component in this framework is available in all Talend products.

### Basic settings

<table>
<thead>
<tr>
<th>Host</th>
</tr>
</thead>
<tbody>
<tr>
<td>SCP IP address.</td>
</tr>
</tbody>
</table>

Listening port number of the SCP server.

SCP user name.

SCP authentication method.

SCP password.
To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

File path on the remote directory.

Name of the file to check.

### Advanced settings

<table>
<thead>
<tr>
<th>tStatCatcher Statistics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Select this check box to collect log data at the component level.</td>
</tr>
</tbody>
</table>

### Global Variables

<table>
<thead>
<tr>
<th>Global Variables</th>
</tr>
</thead>
<tbody>
<tr>
<td>ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box.</td>
</tr>
</tbody>
</table>

FILENAME: the name of the file being processed. This is a Flow variable and it returns a string.

STATUS: the execution result of the component. This is an After variable and it returns a string.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. |
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

| Usage rule | This component is typically used as a single-component subJob but can also be used with other components. |

Handling a file using SCP

In this scenario, a six-component Job checks if a defined file exists in a specified directory on a remote SCP server, and returns a message to indicate the result of the verification. If the file doesn’t exist in that directory, the Job will put the local file to the SCP server, and then get the file from the SCP server to another defined local directory to verify that the file has been uploaded correctly.
Dropping and linking the components

Procedure

1. Add the following six components by typing their names on the design workspace or dropping them from the Palette to the design workspace: **tSCPConnection**, **tSCPFileExists**, **tJava**, **tSCPPut**, **tSCPGet**, and **tSCPClose**.

2. Connect the **tSCPConnection** component to the **tSCPFileExists** component using a Trigger > On Subjob Ok connection.

3. Connect the **tSCPFileExists** component to the **tJava** component using a Trigger > On Component Ok connection, and to the **tSCPPut** component using a Trigger > Run if connection.

4. Connect the **tSCPPut** component to the **tSCPGet** component using a Trigger > On Subjob Ok connection.

5. Connect the **tSCPGet** component to the **tSCPClose** component using a Trigger > On Subjob Ok connection.

Configuring the tSCPConnection component

Procedure

1. Double-click the **tSCPConnection** component to open its Basic settings view.

   ![tSCPConnection_1](image)

2. Enter the host name or IP address of the SCP server and the port number in the corresponding field.

3. Enter the user name used for connection in the Username field.

4. Select Password from the Authentication method drop-down list.

5. Click the [...] button next to the Password text box, then in the pop-up Enter a new password dialog box, enter the password between double quotes and click OK to save the change.
**Configuring file existence verification**

**Procedure**

1. Double-click the `tSCPFileExists` component to open its **Basic settings** view.

2. Select the **Use an existing connection** check box and then select the connection you have configured from the **Component List**.

3. In the **Filename** field, enter the name of the file to be checked between double quotes. In this example, it is "testscp.txt".

4. Double-click the `tJava` component to open its **Basic settings** view.

5. In the **Code** field, enter the following code:

   ```java
   System.out.println((String)globalMap.get("tSCPFileExists_1_FILENAME"));
   System.out.println((String)globalMap.get("tSCPFileExists_1_STATUS"));
   ```

6. Select the **Component** tab and click the **If** connection to open its **Basic settings** view.

7. In the **Condition** field, enter the following code:

   ```java
   !((String)globalMap.get("tSCPFileExists_1_STATUS").equals("File exists."
   ```

This way, if the file doesn’t exist in the defined directory, the rest of the Job will be executed.

**Configuring the tSCPPut component**

**Procedure**

1. Double-click the `tSCPPut` component to open its **Basic settings** view.
2. Select the Use an existing connection check box and then select the connection you have configured from the Component List.

3. Click the [+] button to add one row in the Filelist table, and enter the full local path of the file to be uploaded in the corresponding Source column. In this example, it is “D:/SCPPut/testscp.txt”.

Configuring the tSCPGet component

Procedure

1. Double-click the tSCPGet component to open its Basic settings view.

2. Select the Use an existing connection check box and then select the connection you have configured from the Component List.

3. In the Local directory field, enter or click the [...] button to browse to the directory under which the file will be stored. In this example, it is “D:/SCPGet”.

4. Select append from the Overwrite or Append drop-down list.

5. Click the [+] button to add one row in the Filelist table, and then enter the path of the file to be retrieved from the SCP server in the corresponding Source column. In this example, it is “./testscp.txt”.

Configuring the tSCPClose component

Procedure

1. Double-click the tSCPClose component to open its Basic settings view.
2. Select the connection you have configured from the **Component List**.

## Executing the Job

### Procedure

1. Press **Ctrl+S** to save the Job.
2. Make sure the file `testscp.txt` exists in the local directory `D:/SCPPut`, and does not exist in the local directory `D:/SCPGet` and the home directory of the SCP server.
3. Press **F6** to run the Job.

The file verification information is displayed on the **Run** console.

4. Go to the local directory `D:/SCPGet` and the home directory of the SCP server, you will see the file `testscp.txt` there.
tSCPFileList

Lists files from the defined SCP server.
tSCPFileList iterates, over a fully encrypted channel, on files in a given directory on a remote host.

**tSCPFileList Standard properties**

These properties are used to configure tSCPFileList running in the Standard Job framework.
The Standard tSCPFileList component belongs to the Internet family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use an existing connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Specify the host name or IP address of the SCP server.</td>
<td></td>
</tr>
<tr>
<td>Specify the listening port number of the SCP server.</td>
<td></td>
</tr>
<tr>
<td>Fill in the user name to access the SCP server.</td>
<td></td>
</tr>
<tr>
<td>Select one of the SCP authentication methods from the drop-down list, <strong>Public key</strong>, <strong>Password</strong>, or <strong>Keyboard Interactive</strong>.</td>
<td></td>
</tr>
<tr>
<td>Enter the password to access the SCP server. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. This field appears only when <strong>Password</strong> or <strong>Keyboard Interactive</strong> is selected from the Authentication method drop-down list.</td>
<td></td>
</tr>
<tr>
<td>Enter the passphrase for the public key. To enter the passphrase, click the [...] button next to the passphrase field, and then in the pop-up dialog box enter the passphrase between double quotes and click OK to save the settings. This field appears only when <strong>Public key</strong> is selected from the Authentication method drop-down list.</td>
<td></td>
</tr>
<tr>
<td>Browse to or type in the path to the private key. This field appears only when <strong>Public key</strong> is selected from the Authentication method drop-down list.</td>
<td></td>
</tr>
<tr>
<td>Specify the character used to separate multiple commands.</td>
<td></td>
</tr>
</tbody>
</table>
Click the [+ ] button to add a command or a set of commands to list files in a given directory on the SCP server.

</table>

**Attachments**

Specify the file(s) attached and sent along with the email message. Click the [+] button to add as many rows as needed and set the value of the following columns for each row:
- **File**: Enter the path to the attached file or the path to the folder if all files directly under it will be attached.
- **Content Transfer Encoding**: Click the cell and select a content transfer encoding value from the list.

**Other Headers**

Click the plus button to add as many lines as needed where you can type the Key and the corresponding Value of any header information that does not belong to the standard header.

**SMTP Host and Port**

IP address of SMTP server used to send emails.
### SSL Support
Select this check box to authenticate the server at the client side via an SSL protocol.

### STARTTLS Support
Select this check box to authenticate the server at the client side via a STARTTLS protocol.

### Importance
Select in the list the priority level of your messages.

### Need authentication / Username and Password
Select this check box and enter a username and a password in the corresponding fields if this is necessary to access the service.

To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

### Die on error
This check box is selected by default. Clear the check box to skip the row on error and complete the process for error-free rows.

---

### Advanced settings

<table>
<thead>
<tr>
<th><strong>MIME subtype from the ‘text’ MIME type</strong></th>
<th>Select in the list the structural form for the text of the message.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Encoding type</strong></td>
<td>Select the encoding from the list or select <strong>Custom</strong> and define it manually.</td>
</tr>
<tr>
<td><strong>tStatCatcher Statistics</strong></td>
<td>Select this check box to gather the Job processing metadata at a Job level as well as at each component level.</td>
</tr>
</tbody>
</table>

---

### Global Variables

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it. For further information about variables, see **Talend Studio User Guide**. |

---

### Usage

| **Usage rule** | This component is typically used as one subjob but can also be used as output or end object. It can be connected to other components with either **Row** or **Iterate** links. |
**Sending an email on error**

This scenario creates a three-component Job which sends an email to defined recipients when an error occurs.

1. Drop the following components from your Palette to the design workspace: `tFileInputDelimited`, `tFileOutputXML`, `tSendMail`.
2. Define `tFileInputDelimited` properties. Related topic: `tFileInputDelimited` on page 1015.
3. Right-click on the `tFileInputDelimited` component and select `Row > Main`. Then drag it onto the `tFileOutputXML` component and release when the plug symbol shows up.
4. Define `tFileOutputXML` properties.
5. Drag a Run on Error link from `tFileDelimited` to `tSendMail` component.
6. Define the `tSendMail` component properties:
   - Enter the recipient and sender email addresses, as well as the email subject.
   - Enter a message containing the error code produced using the corresponding global variable. Access the list of variables by pressing Ctrl+Space.
   - Add attachments and extra header information if any. Type in the SMTP information.
In this scenario, the file containing data to be transferred to XML output cannot be found. tSendMail runs on this error and sends a notification email to the defined recipient.
tServerAlive

Validates the status of the connection to a specified host.

tServerAlive checks whether the connection to a specified host is up or down, which is indicated by the boolean value returned by the global variable SERVER_ALIVE_RESULT.

### tServerAlive Standard properties

These properties are used to configure tServerAlive running in the Standard Job framework.

The Standard tServerAlive component belongs to the Misc family.

The component in this framework is available in all Talend products.

#### Basic settings

Validating the status of the connection to a remote host

In this scenario, **tServerAlive** is used to ping a remote host and the value of its global variable `SERVER_ALIVE_RESULT` is extracted to show the connection status.

Dropping and linking components

Procedure

1. Drop the following components from the **Palette** onto the design workspace: **tServerAlive**, **tFixedFlowInput**, and **tLogRow**.
2. Connect **tServerAlive** to **tFixedFlowInput** using a **Trigger > On Subjob Ok** connection.
3. Connect **tFixedFlowInput** to **tLogRow** using a **Row > Main** connection.

![Diagram showing component connections](image)

Configuring the components

Procedure

1. Double-click **tServerAlive** to open its **Basic settings** view.

   ![Basic settings view](image)

2. In the **Protocol** drop-down list, select **Ping**.
3. In the **Host** field, enter the IP address of the remote server to ping.
4. In the **Timeout Interval** field, enter the timeout interval in seconds.

5. Double-click **tFixedFlowInput** to open its **Basic settings** view.

![Basic settings view](image)

6. Click the [...] button next to **Edit schema** to open the schema editor.

![Schema editor](image)

7. Click the [+] button to add one column, namely **status**, of the boolean type. Click **OK** to validate the schema and close the editor.

   In the dialog box that appears, click **Yes** to propagate the changes to the subsequent component.

8. In the **Values** table, press the **Ctrl + Space** keys in the **Value** field to select **tServerAlive_1_SERVER_ALIVE_RESULT** from the variable list.
9. Double-click **tLogRow** to open its **Basic settings** view.

10. Select **Table (print values in cells of a table)** for a better display of the results.

**Saving and executing the Job**

**Procedure**

1. Press **Ctrl+S** to save your Job.
2. Press **F6** to execute the Job.

```
[statistics] connecting to socket on port 3516
[statistics] connected

<table>
<thead>
<tr>
<th>tLogRow_1</th>
</tr>
</thead>
<tbody>
<tr>
<td>status</td>
</tr>
<tr>
<td>true</td>
</tr>
</tbody>
</table>
```

**Results**

As shown above, the remote server is pingable.
**tServiceNowConnection**

Opens a connection to a ServiceNow instance that can then be reused by other ServiceNow components.

**tServiceNowConnection Standard properties**

These properties are used to configure tServiceNowConnection running in the Standard Job framework.

The Standard tServiceNowConnection component belongs to the Business and the Cloud families.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>URL</th>
<th>Enter the URL of the ServiceNow instance to be connected.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Username and Password</strong></td>
<td>Enter the user authentication data to connect to the ServiceNow instance. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is more commonly used with other ServiceNow components. |
Related scenario

No scenario is available for the Standard version of this component yet.
tServiceNowInput

Accesses ServiceNow and retrieves data from it.
tServiceNowInput retrieves data from ServiceNow according to the specified conditions.

**tServiceNowInput Standard properties**

These properties are used to configure tServiceNowInput running in the Standard Job framework.
The Standard tServiceNowInput component belongs to the Business and the Cloud families.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Use Existing Connection</th>
<th>Select this check box and in the Component List click the relevant connection component to reuse the connection details you already defined.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Note:</strong> When a Job contains the parent Job and the child Job, if you need to share an existing connection between the two levels, for example, to share the connection created by the parent Job with the child Job, you have to:</td>
<td></td>
</tr>
<tr>
<td>1. In the parent level, register the database connection to be shared in the <strong>Basic settings</strong> view of the connection component which creates that very database connection.</td>
<td></td>
</tr>
<tr>
<td>2. In the child level, use a dedicated connection component to read that registered database connection.</td>
<td></td>
</tr>
<tr>
<td>For an example about how to share a database connection across Job levels, see Talend Studio User Guide.</td>
<td></td>
</tr>
</tbody>
</table>

| URL | Enter the URL of the ServiceNow instance to be connected. |
| Username and Password | Enter the user authentication data to connect to the ServiceNow instance. |
| To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. |

| Table | Select the name of the table from which the data will be retrieved or select Use Custom Table and in the Custom Table Name field displayed enter the table name. |

| Schema and Edit schema | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields. |
| • **Built-In:** You create and store the schema locally for this component only. |
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Conditions

Specify search conditions to retrieve only the data that matches the criteria by clicking the **[+]** button to add as many conditions as needed and then setting the following parameters for each condition:

- **Input column**: click in the cell and select the column of the input schema on which the search condition is to be set.
- **Operator**: click in the cell and select an operator for the search condition.
- **Value**: enter the value for the corresponding column for the search condition.

Advanced settings

- **Trim all columns**: Select this check box to remove the leading and trailing whitespaces from all columns.
- **Limit**: Enter the maximum number of records to be retrieved.
- **Advanced Query**: Select this check box to enter filtering conditions combined with **AND** and **OR** logical operators. You can enter query statements in this field through copy/paste operations. For information about the logical operators, see **Operators available for filters and queries** and **Generate an encoded query string through a filter**. The **Conditions** field in the **Basic settings** view is not available if you select this check box.

- **tStatCatcher Statistics**: Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

Global Variables

- **Global Variables**: 
  - **NB_LINE**: the number of rows processed. This is an After variable and it returns an integer.
  - **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the
Die on error check box is cleared, if the component has this check box.

A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

Usage

Usage rule | This component is usually used as a start component in a Talend flow and it requires an output component.
---|---

Dynamic settings | Click the [+] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio.

The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable.

For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide.

Related scenario

No scenario is available for the Standard version of this component yet.
**tServiceNowOutput**

Performs the defined action on the data on ServiceNow.

tServiceNowOutput inserts or updates data on ServiceNow.

**tServiceNowOutput Standard properties**

These properties are used to configure tServiceNowOutput running in the Standard Job framework.
The Standard tServiceNowOutput component belongs to the Business and the Cloud families.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>

| Dynamic settings | Click the [+ ] button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. The Dynamic settings table is available only when the Use an existing connection check box is selected in the Basic settings view. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

## Related scenario

No scenario is available for the Standard version of this component yet.
**tSetEnv**

Adds variables temporarily to system environment during the execution of a Job.

tSetEnv creates variables and execute a Job script through communicating the information about the newly created variables between subJobs. After job execution, the newly created variables are deleted.

**tSetEnv Standard properties**

These properties are used to configure tSetEnv running in the Standard Job framework.

The Standard tSetEnv component belongs to the System family.

The component in this framework is available in all Talend products.

**Basic settings**

| Parameters | Click the plus button to add the variables needed for the job. name: Enter the syntax for the new variable. value: Enter a parameter value according to the context. append: Select this check box to add the new variable at the end. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the processing metadata at the Job level as well as at each component level. |

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | tSetEnv can be used as a start or an intermediate component. |
Modifying a variable during a Job execution

The following scenario is made of two Jobs parent and child. With the tSetEnv component, you can transfer and modify in a child Job a value created in a parent Job. As part of this Job, the tMsgBox components allow you to display, for information purposes only, that a variable is properly set, via an info-box.

To modify the value of the parent Job by using a variable set in the tSetEnv component, do as described in the following sections:

Drop and link components

Procedure

1. Create a first Job named parentJob: right-click on the Job Design node of the Repository, and choose Create a Job.
2. From the Palette, drop a tSetEnv component, two tMsgBox components, and one tRunJob component onto the design workspace.
3. Connect the tSetEnv component to a first tMsgBox component with a OnSubjobOk link: right-click on the start component, select Trigger, then OnSubjobOk. Then click on the end component you want to connect.
4. Connect the first tMsgBox component to the tRunJob with a OnSubjobOk link.
5. Then connect the tRunJob component to the second tMsgBox with a OnSubjobOk link.

7. From the Palette, drop a tSetEnv component onto the design workspace.
8. Connect the tSetEnv component to the tMsgBox with a OnSubjobOk link: right-click on the start component, select Trigger, then OnSubjobOk. Then click on the end component you want to connect.
Results

Set the components

About this task

In this example, the value set in the parent Job is transferred to the child Job. There, it is modified and adopts the value of the child Job, and then transferred to the parent Job again.

Procedure

1. In parentJob, select the tSetEnv component and click the Component tab. Add a variable row by clicking the [+] button to set the initial value of the variable. Type Variable_1 in the Name field, and Parent job value in the Value field.

2. Select the first tMsgBox component, and click the Component tab. In the Message field, type the message displayed in the info-box which confirms that your variable has properly been taken into account. For example: "Parent:"+System.getProperty("Variable_1") displays the variable set in the tSetEnv component (here Parent job value).

3. Select the second tMsgBox component, and click the Component tab. In the Message field, type the "Parent:"+System.getProperty("Variable_1") line again. It makes the variable set in the child Job appear.

4. Select the tRunJob component and click the Component tab. In the Job field, type the name of your child Job, here ChildJob. This will run the child Job when you run the parent Job.

5. Now double-click the tRunJob component to open the child Job ChildJob.
6. Select the **tSetEnv** component, and click the **Component** tab. Add a variable row by clicking the **[+]** button to set the initial value of the variable. Type **Variable_1** in the **Name** field, and **Child job value** in the **Value** field.

7. Select the **tMsgBox** component and click the **Component** tab. In the **Message** field, type the message displayed in the info-box which confirms that your variable has properly been taken into account. For example: "Son:"+System.getProperty("Variable_1") displays the variable set in the **tSetEnv** component (here **Child job value**).

8. Save your Job, go back to **parentJob**, then run the Job by pressing **F6**.

**Run the Job**

Three info-boxes are displayed one after the other:

- **Parent: Parent job value**: parent Job’s value is **Parent job value**.
- **Child: Child job value**: Child Job’s value is **Child job value**.
- **Parent: Child job value**: parent Job’s value was modified by the variable set in the **tSetEnv** of the child Job, then transferred again to the parent Job. parent Job’s value is now the one set in the child Job.
tSetGlobalVar

Facilitates the process of defining global variables.
tSetGlobalVar allows you to define and set global variables in GUI.

**tSetGlobalVar Standard properties**

These properties are used to configure tSetGlobalVar running in the Standard Job framework.
The Standard tSetGlobalVar component belongs to the Custom Code family.
The component in this framework is available in all Talend products.

**Basic settings**

| Variables | This table contains two columns.  
**Key**: Name of the variable to be called in the code.  
**Value**: Value assigned to this variable. |

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| Global Variables | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box.  
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.  
To fill up a field or expression with a variable, press **Ctrl + Space** to access the variable list and choose the variable to use from it.  
For further information about variables, see Talend Studio User Guide. |

**Usage**

| Usage rule | This component is generally used as a one-component subjob. |
| Limitation | Knowledge of Java language is required. |
Printing out the content of a global variable

This scenario is a simple Job that prints out the value of a global variable defined in the `tSetGlobalVar` component.

Setting up the Job

Procedure

1. Drop the following components from the Palette onto the design workspace: `tSetGlobalVar` and `tJava`.
2. Connect the `tSetGlobalVar` component to the `tJava` component using a Trigger > OnSubjobOk connection.

Configuring the `tSetGlobalVar` component

Procedure

1. Double-click the `tSetGlobalVar` component to display its Basic settings view.

<table>
<thead>
<tr>
<th>Variables</th>
<th></th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>Key</td>
<td>Value</td>
<td></td>
</tr>
<tr>
<td>&quot;K1&quot;</td>
<td>&quot;20&quot;</td>
<td></td>
</tr>
</tbody>
</table>

2. Click the plus button to add a line in the Variables table, and fill the Key and Value fields with K1 and 20 respectively.
3. Then double-click the `tJava` component to display its Basic settings view.

```
String foo = "bar";
String K1;
String Result = "The value is:";
Result = Result + globalMap.get("K1");
System.out.println(Result);
```
4. In the **Code** area, type in the following lines:

```
String foo = "bar";
String K1;
String Result = "The value is:";

Result = Result + globalMap.get("K1");

System.out.println(Result);
```

In this use case, we use the `Result` variable. To access the global variable list, press **Ctrl + Space** bar on your keyboard and select the relevant global parameter.

**Job execution**

Save your Job and press **F6** to execute it.

The content of global variable `K1` is displayed on the console.

```
[statistics] connecting to socket on port 3489
[statistics] connected
The value is:20
Job SetGlobalVar ended at 16:22 25/02/2011. [exit code=0]
```
tSetKerberosConfiguration

Sets the relevant information for Kerberos authentication.

tSetKerberosConfiguration is designed to configure Kerberos authentication for enhanced security of network communications.

For more information on the Kerberos protocol, go to http://www.kerberos.org.

**tSetKerberosConfiguration Standard properties**

These properties are used to configure tSetKerberosConfiguration running in the Standard Job framework.

The Standard tSetKerberosConfiguration component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>

</table>

Related scenarios

No scenario is available for the Standard version of this component yet.
tSetKeystore

Sets the authentication data type between **PKCS 12** and **JKS**.

tSetKeystore submits authentication data of a truststore with or without keystore to validation for the SSL connection.

**tSetKeystore Standard properties**

These properties are used to configure tSetKeystore running in the Standard Job framework.
The Standard tSetKeystore component belongs to the Internet family.
The component in this framework is available in all **Talend products**.

**Basic settings**

<table>
<thead>
<tr>
<th><strong>TrustStore type</strong></th>
<th>Select the type of the TrustStore to be used. It may be <strong>PKCS 12</strong> or <strong>JKS</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>TrustStore file</strong></td>
<td>Type in the path, or browse to the certificate TrustStore file (including filename) that contains the list of certificates that the client trusts.</td>
</tr>
<tr>
<td><strong>TrustStore password</strong></td>
<td>Type in the password used to check the integrity of the TrustStore data.</td>
</tr>
</tbody>
</table>
| **Need Client authentication** | Select this check box to validate the keystore data. Once doing so, you need complete three fields:  
  - **KeyStore type**: select the type of the keystore to be used. It may be **PKCS 12** or **JKS**.  
  - **KeyStore file**: type in the path, or browse to the file (including filename) containing the keystore data.  
  - **KeyStore password**: type in the password for this keystore. |
| **Check server identity** | Select this check box to make the Job verify the match between the hostname of the URL and the hostname of the server. If they mismatch, the verification mechanism asks whether this connection should be allowed. |

**Advanced settings**

| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at a Job level as well as at each component level. |

**Global Variables**

| **Global Variables** | **ERROR_MESSAGE**: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the **Die on error** check box is cleared, if the component has this check box. |
A Flow variable functions during the execution of a component while an After variable functions after the execution of the component.

To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it.

For further information about variables, see Talend Studio User Guide.

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is used standalone.</th>
</tr>
</thead>
</table>

| Connections | Outgoing links (from this component to another): Trigger: Run if, On Subjob Ok, On Subjob Error, On Component Ok; On Component Error. |

Incoming links (from one component to this one):

For further information regarding connections, see Talend Studio User Guide.

| Limitation | n/a. |

### Extracting customer information from a private WSDL file

This scenario describes a three-component Job that connects to a private WSDL file in order to extract customer information.

The WSDL file used in this Job accesses the corresponding web service under the SSL protocol. For this purpose, the most relative code in this file reads as follows:

```xml
<wsdl:port name="CustomerServiceHttpSoap11Endpoint" binding="ns:CustomerServiceSoap11Binding">
</wsdl:port>
```

Accordingly, we enter the following code in the `server.xml` file of Tomcat:

```xml
<Connector port="8443" protocol="HTTP/1.1" SSLEnabled="true"
  maxThreads="150" scheme="https" secure="true"
  clientAuth="true" sslProtocol="TLS"
  keystoreFile="D:/server.keystore" keystorePass="password"
  keystoreType="JKS"
  truststoreFile="D:/server.p12" truststorePass="password"
  truststoreType="PKCS12"/>
```

So we need keystore files to connect to this WSDL file. To replicate this Job, proceed as follows:

- Drop the following components from the Palette onto the design workspace: tSetKeystore, tWebService, and tLogRow.
- Right-click **tSetKeystore** to open its contextual menu.
- In this menu, select **Trigger > On Subjob Ok** to connect this component to **tWebService**.
- Right-click **tWebService** to open its contextual menu.
- In this menu, select **Row > Main** to connect this component to **tLogRow**.
- Double-click **tSetKeystore** to open its **Basic settings** view and define the component properties.

### tSetKeystore_1

<table>
<thead>
<tr>
<th>Basic settings</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>TrustStore type</td>
<td>PKCS12</td>
</tr>
<tr>
<td>TrustStore file</td>
<td>D:/server.p12*</td>
</tr>
<tr>
<td>TrustStore password</td>
<td>&quot;password&quot;</td>
</tr>
<tr>
<td>Need Client authentication</td>
<td></td>
</tr>
<tr>
<td>KeyStore type</td>
<td>JKS</td>
</tr>
<tr>
<td>KeyStore file</td>
<td>D:/server.keystore*</td>
</tr>
<tr>
<td>KeyStore password</td>
<td>&quot;password&quot;</td>
</tr>
</tbody>
</table>

- In the **TrustStore type** field, select **PKCS12** from the drop-down list.
- In the **TrustStore file** field, browse to the corresponding truststore file. Here, it is **server.p12**.
- In the **TrustStore password** field, type in the password for this truststore file. In this example, it is **password**.
- Select the **Need Client authentication** check box to activate the keystore configuration fields.
- In the **KeyStore type** field, select **JKS** from the drop-down list.
- In the **KeyStore file** field, browse to the corresponding keystore file. Here, it is **server.keystore**.
- Double-click **tWebService** to open the component editor, or select the component in the design workspace and in the **Basic settings** view, click the three-dot button next to **Service configuration**.
In the WSDL field, browse to the private WSDL file to be used. In this example, it is `CustomerService.wsdl`.

Click the refresh button next to the WSDL field to retrieve the WSDL description and display it in the fields that follow.

In the Port Name list, select the port you want to use, `CustomerServiceHttpSoap11Endpoint` in this example.

In the Operation list, select the service you want to use. In this example the selected service is `getCustomer(parameters):Customer`.

Click Next to open a new view in the editor.

In the panel to the right of the Input mapping view, the input parameter of the service displays automatically. However, you can add other parameters if you select `[+] parameters` and then click the plus button on top to display the Parameter Tree dialog box where you can select any of the listed parameters.
The Web service in this example has only one input parameter, **ID**.

- In the **Expression** column of the **parameters.ID** row, type in the customer ID of your interest between quotation marks. In this example, it is **A00001**.
- Click **Next** to open a new view in the editor.

In the **Element** list to the left of the view, the output parameter of the web service displays automatically. However, you can add other parameters if you select **[+] parameters** and then click the plus button on top to display the **Parameter Tree** dialog box where you can select any of the parameters listed.

The Web service in this example has four output parameter: **return.address**, **return.email**, **return.name** and **return.phone**.

You now need to create a connection between the output parameter of the defined Web service and the schema of the output component. To do so:

- In the panel to the right of the view, click the three-dot button next to **Edit Schema** to open a dialog box in which you can define the output schema.

  - In the schema editing dialog box, click the plus button to add four columns to the output schema.
  - Click in each column and type in the new names, **Name**, **Phone**, **Email** and **Address** in this example. This will retrieve the customer information of your interest.
• Click **OK** to validate your changes and to close the schema editing dialog box.
• In the **Element** list to the right of the editor, drag each parameter to the field that corresponds to the column you have defined in the schema editing dialog box.

**Note:**
If available, use the **Auto map!** button, located at the bottom left of the interface, to carry out the mapping operation automatically.

• Click **OK** to validate your changes and to close the editor.
• In the design workspace, double-click **tLogRow** to open its **Basic settings** view and define its properties.
• Click **Sync columns** to retrieve the schema from the preceding component.
• Save your **Job** and press **F6** to execute it.

The information of the customer with ID *A00001* is returned and displayed in the console of *Talend Studio*.

```
<table>

[statistics] disconnected
Job tSetKeystore ended at 19:01 24/11/2010, [exit code=0]
tSetProxy

Sets the relevant information for proxy setup.

**tSetProxy Standard properties**

These properties are used to configure tSetProxy running in the Standard Job framework.

The Standard tSetProxy component belongs to the Internet family.

The component in this framework is available in all Talend products.

**Basic settings**

| **Use Java Virtual Machine Proxy Configuration** | Select this option to use the following proxy configuration for all the network accesses from the JVM. If this option is cleared, the proxy configuration is used only when the JVM accesses the URIs specified in **URIs to use proxy**. This option is selected by default. |
| **Proxy type** | List of proxy protocols. Four options are available: Http Proxy, Https Proxy, Socks Proxy, and FTP Proxy. **Note:** FTP Proxy is not available if **Use Java Virtual Machine Proxy Configuration** is cleared. |
| **Proxy host** | Address of the proxy server. |
| **Proxy port** | Number of the proxy port. |
| **Use authentication** | Select this option if authentication is enabled on the Https proxy server. **Note:** This option is available when **Https Proxy** is selected from **Proxy type** drop-down list. |
| **Proxy user** | Username for proxy authentication. |
| **Proxy password** | Password for proxy authentication. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings. |
| **URIs to use proxy** | Specify the URIs for which the proxy is used by providing the corresponding host names/host addresses and port numbers in the table. |
Note:
- This table is available if Use Java Virtual Machine Proxy Configuration is cleared.
- For the Port column, a value of −1 specifies to use the proxy when the JVM accesses any ports of the host.

<table>
<thead>

</tbody>
</table>
## Usage

| Usage rule | Typically used as a subjob by itself, tSetProxy is deployed along with other Internet components. |

## Related scenarios

No scenario is available for the Standard version of this component yet.
tSleep

Identifies possible bottlenecks using a time break in the Job for testing or tracking purpose.

tSleep implements a time off in a Job execution. In production, it can be used for any needed pause in the Job to feed input flow for example.

**tSleep Standard properties**

These properties are used to configure tSleep running in the Standard Job framework.
The Standard tSleep component belongs to the Orchestration family.
The component in this framework is available in all Talend products.

**Basic settings**

<table>
<thead>
<tr>
<th>Pause (in second)</th>
<th>Time in second the Job execution is stopped for.</th>
</tr>
</thead>
</table>

**Global Variables**

| Global Variables | ERROR_MESSAGE: the error message generated by the component when an error occurs. This is an After variable and it returns a string. This variable functions only if the Die on error check box is cleared, if the component has this check box. A Flow variable functions during the execution of a component while an After variable functions after the execution of the component. To fill up a field or expression with a variable, press Ctrl + Space to access the variable list and choose the variable to use from it. For further information about variables, see Talend Studio User Guide. |

**Usage**

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>tSleep component is generally used as a middle component to make a break/pause in the Job, before resuming the Job.</th>
</tr>
</thead>
</table>
| Connections | Outgoing links (from this component to another):  
**Row:** Main; Iterate.  
**Trigger:** On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error  
Incoming links (from one component to this one):  
**Row:** Main; Reject; Iterate.  
**Trigger:** On Subjob Ok; On Subjob Error; Run if; On Component Ok; On Component Error; Synchronize; Parallelize. |
Related scenarios

For use cases in relation with tSleep, see Procedure on page 1980.
tSnowflakeBulkExec

Loads data from files in a folder into a Snowflake table. The folder can be in an internal Snowflake stage, an Amazon Simple Storage Service (Amazon S3) bucket, or an Azure container.

Normally, the tSnowflakeOutputBulk and tSnowflakeBulkExec components work together in a two-step process:

1. The tSnowflakeOutputBulk component uploads incoming data to a storage.
2. The tSnowflakeBulkExec component loads the data from a storage into a Snowflake database table.

You can transform the data before it is loaded into the database table in this two-step process. These two steps are fused together in the tSnowflakeOutputBulkExec component, detailed in a separate section.

tSnowflakeBulkExec Standard properties

These properties are used to configure tSnowflakeBulkExec running in the Standard Job framework. The Standard tSnowflakeBulkExec component belongs to the Cloud family.

The component in this framework is available in all subscription-based Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>• Built-In: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
<td></td>
</tr>
<tr>
<td>• Repository: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
<td></td>
</tr>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>Account</td>
<td>In the Account field, enter, in double quotation marks, the account name that has been assigned to you by Snowflake. This field is available only when Use this Component is selected from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>
| **Snowflake Region** | Select an AWS region or an Azure region from the Snowflake Region drop-down list.  
This field is available only when Use this Component is selected from the Connection Component drop-down list. |
|---------------------|-------------------------------------------------------------------------------------------------|
| **User Id and Password** | Enter, in double quotation marks, your authentication information to log in Snowflake.  
- In the User ID field, enter, in double quotation marks, your login name that has been defined in Snowflake using the LOGIN_NAME parameter of Snowflake.  
  For details, ask the administrator of your Snowflake system.  
- To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.  
This field is available only when Use this Component is selected from the Connection Component drop-down list. |
| **Warehouse** | Enter, in double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.  
This field is available only when Use this Component is selected from the Connection Component drop-down list. |
| **Schema** | Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.  
This field is available only when Use this Component is selected from the Connection Component drop-down list. |
| **Database** | Enter, in double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.  
This field is available only when Use this Component is selected from the Connection Component drop-down list. |
| **Table** | Click the [...] button and in the displayed wizard, select the Snowflake table to be used.  
To load the data into a new table, select Use custom object in the wizard and enter the name of the new table in Object Name field. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
**Built-In:** You create and store the schema locally for this component only.  
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select String for the corresponding data in the Type column of the schema editor wizard. |
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected.

</table>
## Advanced settings

<table>
<thead>
<tr>
<th>Feature</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, <code>encryption=1;clientname=Talend</code>. This field is available only when you select <strong>Use this Component</strong> from the Connection Component drop-down list and select <strong>Internal</strong> from the Storage drop-down list in the Basic settings view.</td>
</tr>
</tbody>
</table>
| **Use Custom Snowflake Region** | Select this check box to specify a custom Snowflake region. This option is available only when you select **Use This Component** from the Connection Component drop-down list in the Basic settings view.  
- **Region ID**: enter a region ID in double quotation marks, for example `eu-west-1` or `east-us-2.azure`.  
For more information on Snowflake Region ID, see Supported Regions. |
| **Login Timeout** | Specify the timeout period (in minutes) of Snowflake login attempts. An error will be generated if no response is received in this period. |
| **Role** | Enter, in double quotation marks, the default access control role to use to initiate the Snowflake session. This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For information about Snowflake access control model, see Understanding the Access Control Model. |
| **Allow Snowflake to convert columns and tables to uppercase** | Select this check box to convert lowercase in the defined table name and schema column names to uppercase. Note that unquoted identifiers should match the Snowflake Identifier Syntax.  
If you deselect the check box, all identifiers are automatically quoted.  
This property is not available when you select the Manual Query check box.  
For more information on the Snowflake Identifier Syntax, see Identifier Syntax. |
<p>| <strong>Temporary Table Schema</strong> | Specifies a schema for the temporary table. The schema must exist. |
| <strong>Custom DB Type</strong> | Select this check box to specify the DB type for each column in the schema. This property is available only when you select an action with Create Table from the Table Action drop-down list in the Basic settings. |
| <strong>Delete Storage Files On Success</strong> | Delete all the files in the storage folder once the data is loaded to the table successfully. This field is not available when you select <strong>Use Custom Storage Location</strong>. |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>S3 Max Error Retry</strong></td>
<td>Specify the maximum data loading retries when an error occurs during loading data to or from the S3 folder. This parameter defaults to 3. A value of -1 specifies the maximum possible retries. Only -1 or positive integers are accepted. This field is available when you select S3 from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td><strong>Azure Max Error Retry</strong></td>
<td>Specify the maximum data loading retries when an error occurs during loading data to or from the Azure folder. This parameter defaults to 3. A value of -1 specifies the maximum possible retries. Only -1 or positive integers are accepted. This field is available when you select Azure from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td><strong>Use Custom S3 Connection Configuration</strong></td>
<td>Select this check box if you wish to use your custom S3 configuration. Option: select the parameter from the list. Value: enter the parameter value. This field is available when you select S3 from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td><strong>Use Custom Stage Prefix</strong></td>
<td>Select this check box to specify the path to the folder (with the current stage as the root) from which the data is loaded. You need also to enter the path to the folder in the field provided. For example, to load data stored in the files that are located in myfolder1/myfolder2 under the stage, you need to type &quot;@~/myfolder1/myfolder2&quot; in the field. This field is available when you select Internal from the Storage drop-down list in the Basic settings view. Once selected, the Stage Folder in Basic settings view becomes unavailable.</td>
</tr>
<tr>
<td><strong>Use Custom Storage Location</strong></td>
<td>Select this check box to connect to a custom external storage, for example, S3.</td>

</table>
| **Copy Command Options**                | Set parameters for the COPY INTO command by selecting the following options from the drop-down list. The COPY INTO command is provided by Snowflake. It loads data to a Snowflake database table.  
  - **Default**: Carry out the COPY INTO operation using the default settings, as listed in the frame to the right.  
  - **Table**: Set the COPY INTO operation parameters using the Options table. To set a parameter, click the plus button, select the parameter from the Option column, and set the parameter value in the Value column.  
  - **Manual**: Set the COPY INTO operation parameters in the text frame to the right manually.  
  For information about the parameters of the COPY INTO command, see the COPY INTO command. |
| **tStatCatcher Statistics**             | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>NB_LINE</td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_SUCCESS</td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>NB_REJECT</td>
<td>The number of rows rejected. This is an After variable and it returns an integer.</td>
</tr>
<tr>
<td>ERROR_MESSAGE</td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>This component is an end component of a data flow in your Job. It receives data from other components through the Row &gt; Main link.</td>
<td></td>
</tr>
</tbody>
</table>

Loading data in a Snowflake table using custom stage path

This scenario describes a Job that loads data into a Snowflake table via the internal Snowflake stage configured using the Custom Stage Path property.

The input data contains several records.

<table>
<thead>
<tr>
<th>#Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bill</td>
</tr>
<tr>
<td>Franklin</td>
</tr>
<tr>
<td>Jimmy</td>
</tr>
</tbody>
</table>

Then, the input data is inserted into a Snowflake table and the path to the internal Snowflake stage is customized in the Advanced settings of tSnowflakeOutputBulk and tSnowflakeBulkExec.

Finally, the input data is outputted from the tSnowflake table to the console.
Creating a Job for loading data using custom stage path

Create a Job to open a connection to access a Snowflake database, then create a Snowflake table and several records and insert these records into the table via the internal Snowflake stage configured using the Custom Stage Path property, and finally get and display the records on the console.

Procedure

1. Create a new Job and add a `tSnowflakeConnection` component, a `tFixedFlowInput` component, a `tSnowflakeOutputBulk` component, a `tSnowflakeBulkExec` component, a `tSnowflakeInput` component, a `tSnowflakeClose` component, and two `tLogRow` components by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFixedFlowInput` component to the first `tLogRow` component using a Row > Main connection.

3. Do the same to link the first `tLogRow` component to the `tSnowflakeBulkExec` component and link the `tSnowflakeInput` component to the second `tLogRow` component.

4. Link the `tSnowflakeConnection` component to the `tFixedFlowInput` component using a Trigger > OnSubjobOk connection.

5. Do the same to link the `tFixedFlowInput` component to the `tSnowflakeInput` component and the `tSnowflakeInput` component to the `tSnowflakeClose` component.

6. Link the `tSnowflakeOutputBulk` component to the `tSnowflakeBulkExec` component using a Trigger > OnComponentOk connection.

Opening a connection to access a snowflake database

Configure the `tSnowflakeConnection` component to open a connection to access a Snowflake database.

Procedure

1. Double-click the `tSnowflakeConnection` component to open its Basic settings view.
2. In the **Account**, **User Id**, **Password**, **Warehouse**, **Schema** and **Database** fields, specify the authentication information required to access the Snowflake Database.

3. Select an AWS region available for the Snowflake database from the **Snowflake Region** drop-down list. In this example, it is **AWS US West**.

**Loading data to the Snowflake table**

Configure the tSnowflakeOutputBulk and tSnowflakeBulkExec components to load data to the Snowflake table.

**Procedure**

1. Double-click the tFixedFlowInput component to open its **Basic settings** view.

2. Click the **Edit schema** button to define the schema. In this example, the schema has only one column: Name.

3. In the **Mode** area, select **Use Inline Table**. Then add three records. In this example, they are:

   - Bill
   - Franklin
   - Jimmy

4. Double-click the first tLogRow component to open its **Basic settings** view.

5. In the **Mode** area, select **Table** to display data.

6. Double-click the tSnowflakeOutputBulk component to open its **Basic settings** view.
7. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

8. If needed, click the **Sync columns** button to make sure the schema is properly retrieved from the preceding component.

9. Select **Internal** from the **Storage** drop-down list and enter "demo" within double quotes in the **Stage Folder** field.

10. Double-click the **tSnowflakeBulkExec** component to open its **Basic settings** view.

11. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

12. Click the **Table** field to select the table you want to load data. In this example, it is **DEMO_NAMES**.
13. If needed, click the **Sync columns** button to make sure the schema is properly retrieved from the preceding component.

14. Select **INSERT** from the **Output Action** drop-down list to insert data to the table **DEMO_NAMES**.

15. Select **Internal** from the **Storage** drop-down list and enter `demo` in the **Stage Folder** field.

**Using custom stage path to load data**

Configure the **Advanced settings** of the **tSnowflakeOutputBulk** and **tSnowflakeBulkExec** components to use the Custom Stage Path property to load data.

**Procedure**

1. Click **Advanced settings** of the **tSnowflakeOutputBulk** component to open its **Advanced settings** view.

2. Select the **Use Custom Stage Path** check box and enter `@~/demo` within double quotes. As a result, the **Stage Folder** you specified in the **Basic settings** is disabled.

3. Select **Default** from the **Put Command Options** drop-down list.

4. Set **Put Command Error Retry** to 3.

5. Clear the **Stop on non-empty Storage Folder** check box.

6. Click **Advanced settings** of the **tSnowflakeBulkExec** component to open its **Advanced settings** view.
7. Select the **Convert columns and table to uppercase** check box to convert the columns to uppercase.

8. Select **Use Custom Stage Path** and enter `@~/demo` within double quotes. As a result, the Stage Folder you specified in the Basic settings is disabled.

9. Clear the **Use Custom Storage Location** check box.

10. Select **Manual** from the **Copy Command Options** drop-down list and enter `ON_ERROR='continue' FILE_FORMAT=(type=csv field_delimiter=',' compression=gzip field_optionally_enclosed_by='"')` within double quotes.

### Retrieving data from the Snowflake table

Configure the **tSnowflakeInput** component to retrieve data from the Snowflake table, and then configure the second **tLogRow** component to get and display data on the console.

**Procedure**

1. Double-click the **tSnowflakeInput** component to open its **Basic settings** view.

2. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.

3. Click the **Enter** button next to the **Table** field to select the table you want to retrieve data. In this example, it is **DEMO_NAMES**.

4. Click the **Enter** button next to **Edit schema** to open the schema dialog box and define the schema. In this example, the schema has only one column: Name.
5. Click Advanced settings to open the Advanced settings view.

6. Select the Convert columns and table to uppercase check box to convert the columns to uppercase.

7. Double-click the second tLogRow component to open its Basic settings view.

8. In the Mode area, select Table to display data.

**Executing the Job**

**Procedure**

Press Ctrl + S to save the Job and then F6 to execute the Job.
As shown above, the Job is executed successfully and the records are displayed on the console.

**Related scenarios**

For use cases in relation with tSnowflakeBulkExec, see the following scenarios:

- Inserting transformed data in MySQL database on page 2482.
- Inserting data in bulk in MySQL database on page 2489.
- Truncating and inserting file data into an Oracle database on page 2681.
tSnowflakeClose

Closes an active Snowflake connection to release the occupied resources.

**tSnowflakeClose Standard properties**

These properties are used to configure `tSnowflakeClose` running in the Standard Job framework.

The Standard `tSnowflakeClose` component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the connection you need to close from the drop-down list.</td>
</tr>
</tbody>
</table>

**Advanced settings**

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other Snowflake components, especially with the `tSnowflakeConnection` component. |

**Related scenario**

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3407.
**tSnowflakeCommit**

Provides gain in performance.

Using a unique connection, this component commits in one go a global transaction instead of doing that on every row or every batch.

tSnowflakeCommit validates the data processed through the Job into the connected database.

**tSnowflakeCommit Standard properties**

These properties are used to configure tSnowflakeCommit running in the Standard Job framework.

The Standard tSnowflakeCommit component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Connection Component</td>
<td>Select the component that establishes the connection to the database you want to commit.</td>
</tr>
<tr>
<td>Close Connection</td>
<td>Select this option to close the database connection once the commit is done. Clear this check box to continue to use the selected connection once the component has performed its task. This option is selected by default.</td>
</tr>
</tbody>
</table>

**Warning:**

If this component uses a **Row > Main** as the incoming link in a Job, the data passing through the link will be committed row by row. In this case, do not select this option so that all the rows passing through the link can be committed.

### Advanced settings

| tStatCatcher Statistics | Select this check box to collect log data at the component level. |

### Global variables

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |
### Usage

| Usage rule | This component is designed to work with tSnowflakeRow, tSnowflakeBulkExec, and tSnowflakeOutputBulkExec components. When this component works with a tSnowflakeRow component with no input or output row, changes made to the database are committed by the tSnowflakeCommit component. When this component works with a tSnowflakeRow component with an input row, the tSnowflakeCommit component takes the charge of committing changes made to the database if the Commit every option of the tSnowflakeRow component is set to 0 or 1; the tSnowflakeCommit component will be ignored if the value of the Commit every option of the tSnowflakeRow component is larger than 1. |
| Dynamic settings | Click the [+ button to add a row in the table and fill the Code field with a context variable to choose your database connection dynamically from multiple connections planned in your Job. This feature is useful when you need to access database tables having the same data structure but in different databases, especially when you are working in an environment where you cannot change your Job settings, for example, when your Job has to be deployed and executed independent of Talend Studio. Once a dynamic parameter is defined, the Component List box in the Basic settings view becomes unusable. For examples on using dynamic parameters, see Reading data from databases through context-based dynamic connections on page 2446 and Reading data from different MySQL databases using dynamically loaded connection parameters on page 497. For more information on Dynamic settings and context variables, see Talend Studio User Guide. |

### Related scenario for tSnowflakeCommit
tSnowflakeConnection

Opens a connection to Snowflake that can then be reused by other Snowflake components.

**tSnowflakeConnection Standard properties**

These properties are used to configure tSnowflakeConnection running in the Standard Job framework.

The Standard tSnowflakeConnection component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click <strong>Apply</strong>.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Built-In:</strong> The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Repository:</strong> The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td>Account</td>
<td>In the <strong>Account</strong> field, enter, in double quotation marks, the account name that has been assigned to you by Snowflake.</td>
</tr>
<tr>
<td>Authentication Type</td>
<td>Set the authentication type.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Basic:</strong> Select this option if key pair authentication is not enabled.</td>
</tr>
<tr>
<td></td>
<td>• <strong>Key Pair:</strong> Select this option if key pair authentication is enabled.</td>
</tr>
</tbody>
</table>

For information about key pair authentication, see Using Key Pair Authentication.

Before selecting the **Key Pair** option, make sure you have set the key pair authentication data in the Basic settings view of the tSetKeystore component as follows.

- Leave the **TrustStore type** field unchanged;
- Set **TrustStore file** to "";
- Clear the **TrustStore password** field;
- Select **Need Client authentication**;
- Enter the path to the key store file in double quotation marks in the **KeyStore file** field (or click the [...] button to the right of the **KeyStore file** field and navigate to the key store file);
- Enter the key store file password in the **KeyStore password** field;
- Clear the **Check server identity** option.

**User Id**
Enter your login name in double quotation marks.

**Password**
Click the [...] button next to the **Password** field, enter the password in double quotation marks in the pop-up dialog box, and click **OK**.

This field is available if **Basic** is selected from the **Authentication Type** drop-down list.

**Key Alias**
Enter the key pair alias in double quotation marks.

This field is available if **Key Pair** is selected from the **Authentication Type** drop-down list.

**Warehouse**
Enter, in double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Schema**
Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.

**Database**
Enter, in double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.

### Advanced settings

**Auto Commit**
Select this option to automatically commit the changes made to the current database when the connection to the database is terminated.

This option is selected by default.

**Note:** This option has no effect on the **tSnowflakeOutput** component.

**Additional JDBC Parameters**
Specify additional JDBC parameters for the database connection created.

**Use Custom Snowflake Region**
Select this check box to specify a custom Snowflake region. This option is available only when you select **Use This Component** from the **Connection Component** drop-down list in the **Basic settings** view.

- **Region ID:** enter a region ID in double quotation marks, for example `eu-west-1` or `east-us-2.azure`.

For more information on Snowflake Region ID, see **Supported Regions**.

**Login Timeout**
Specify the timeout period (in minutes) of Snowflake login attempts. An error will be generated if no response is received in this period.

**Role**
Enter, in double quotation marks, the default access control role to use to initiate the Snowflake session.
This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For information about Snowflake access control model, see Understanding the Access Control Model.

| tStatCatcher Statistics | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

**Global variables**

| ERROR_MESSAGE | The error message generated by the component when an error occurs. This is an After variable and it returns a string. |

**Usage**

| Usage rule | This component is more commonly used with other Snowflake components. It creates a Snowflake connection and works with other subjobs that reuse this connection using a Trigger link. |

| Tracing Snowflake JDBC logs | If you wish to merge the Snowflake JDBC driver logs with the logs of the current Job, add this JVM argument, `-Dnet.snowflake.jdbc.loggerImpl=net.snowflake.client.log.JDK14Logger`, in the Run > Advanced settings tab of the Job you are running. |

**Related scenario**

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3407.
## tSnowflakeInput

Reads data from a Snowflake table into the data flow of your Job based on an SQL query.

### tSnowflakeInput Standard properties

These properties are used to configure tSnowflakeInput running in the Standard Job framework.

The Standard tSnowflakeInput component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

### Basic settings

<table>
<thead>

</tr>
<tr>
<td><strong>Database</strong></td>
<td>Enter, in double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.</td>
</tr>
<tr>
<td><strong>Table</strong></td>
<td>Click the […] button and in the displayed wizard, select the Snowflake table to be used.</td>
</tr>
</tbody>
</table>

**Schema and Edit Schema**

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.

- **Built-In**: You create and store the schema locally for this component only.
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select String for the corresponding data in the Type column of the schema editor wizard.

Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.

Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected.

**Manual query**

Select this check box and in the **Full SQL query string** field, enter, within double quotation marks, the query statement to be executed. For information about the Snowflake SQL commands, see SQL Command Reference.

**Condition**

Enter, in double quotation marks, the boolean expression to be used to filter data from your Snowflake table. This expression is actually used as WHERE clause in the SELECT query run by tSnowflakeInput.
## Advanced settings

<table>

</tbody>
</table>
Usage

| Usage rule | This component is start component of a data flow in your Job. It sends data to other components via a Row link. |

Writing data into and reading data from a Snowflake table

Here is an example of using Talend Snowflake components to connect to Snowflake, create a Snowflake table, write data into the table, then read data from this table, finally close the connection to Snowflake.

Creating a Job for writing and reading Snowflake data

Create a Job to connect to Snowflake, create a Snowflake table, write data into the table and then read data from the table, finally close the connection to Snowflake.

Before you begin

- The Snowflake data warehouse to be used is started but not in the Suspended status.
- The Snowflake role assigned to you has read and write permissions to the database to be connected.

If you are not sure about these requirements, ask the administrator of your Snowflake system.
Procedure

1. In the Integration perspective of the Studio, create a new Job from the Job Designs node in the Repository tree view.
2. Add a tSnowflakeConnection component, a tSnowflakeRow component, a tFixedFlowInput component, a tSnowflakeOutput component, a tSnowflakeInput component, a tLogRow component, and a tSnowflakeClose component to the Job.
3. Connect the tFixedFlowInput component to the tSnowflakeOutput component using a Row > Main connection.
4. Do the same to connect the tSnowflakeInput component to the tLogRow component.
5. Connect the tSnowflakeConnection component to the tSnowflakeRow component using a Trigger > On Subjob Ok connection.
6. Do the same to connect the tSnowflakeRow component to the tFixedFlowInput component, the tFixedFlowInput component to the tSnowflakeInput component, and the tSnowflakeInput component to the tSnowflakeClose component.

Connecting to Snowflake

Configure the tSnowflakeConnection component to connect to Snowflake.

Procedure

1. Double-click the tSnowflakeConnection component to open its Basic settings view.
2. In the Account field, enter the account name assigned by Snowflake.
3. In the Snowflake Region field, select the region where the Snowflake database locates.
4. In the User Id and the Password fields, enter the authentication information accordingly.
   Note that this user ID is your user login name. If you do not know your user login name yet, ask the administrator of your Snowflake system for details.
5. In the Warehouse field, enter the name of the data warehouse to be used in Snowflake.
6. In the Schema field, enter the name of the database schema to be used.
7. In the Database field, enter the name of the database to be used.

Creating a Snowflake table

Configure the tSnowflakeRow component to create a new table.

Procedure

1. Double-click the tSnowflakeRow component to open its Basic settings view on the Component tab.
2. From the Connection Component drop-down list, select the tSnowflakeConnection component to reuse the connection created by it. In this example, it is tSnowflakeConnection_1.
3. In the Query field, enter the SQL statement used to create a new table into which the data will be written.
In this example, the following SQL statement is used to create or replace a table `EMPLOYEE` with four columns, `ID` of INT type, `NAME` of VARCHAR type, `ONBOARD` of DATE type, and `SALARY` of VARIANT type.

```
"CREATE OR REPLACE TABLE EMPLOYEE (" +
  "ID INT NOT NULL primary key," +
  "NAME VARCHAR (50), " +
  "ONBOARD DATE," +
  "SALARY VARIANT" +
  ") COMMENT = 'Created By Doc Team'"
```

**Writing data into Snowflake**

Configure the `tFixedFlowInput` component and the `tSnowflakeOutput` component to write data into Snowflake.

**Procedure**

1. Double-click the `tFixedFlowInput` component to open its Basic settings view.

   ![tFixedFlowInput component](image)

   - **Schema**: Built-In
   - **Mode**: Use Single Table
   - **Values**:
     - Column: ID, NAME, SALARY, ONBOARD
     - Value: Numeric.sequence("id",1,1), TalendDataGenerator.getFirstName(), TalendDate.getRandomDate("2007-09-01","2017-09-01"), 
     "\"Salary\"" + Numeric.random(100000,200000) +"

2. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding four columns, `ID` of int type, `NAME` and `SALARY` of String type, and `ONBOARD` of Date type.

   ![Schema of tfixedFlowInput_1](image)
3. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

4. In the Number of rows field, enter the number of records to be generated, 5 in this example.

5. In the Mode area, select Use Single Table and specify the value for each column.
   - **ID**: the automatically incremented number generated by the routine `Numeric.sequence("id",1,1)`.
   - **NAME**: the random first name generated by the routine `TalendDataGenerator.getFirstName()`.
   - **ONBOARD**: the random date generated by the routine `TalendDate.getRandomDate("2007-09-01", "2017-09-01")`.
   - **SALARY**: the semi-structured JSON data with the format `{"Salary": value}`, where the salary value is generated by the routine `Numeric.random(100000, 200000)`.

6. Double-click the **tSnowflakeOutput** component to open its Basic settings view.

7. From the Connection Component drop-down list, select the **tSnowflakeConnection** component to reuse the connection created by it.

8. Click the [...] button next to the Table field and in the pop-up dialog box, select the Use custom object check box and enter the name of the table into which the data will be written in the Object Name field. In this example, it is **EMPLOYEE**, the table created by the **tSnowflakeRow** component. When done, click OK to close the dialog box.

9. From the Output action drop-down list, select Insert to write data to the table **EMPLOYEE**.

### Reading data from Snowflake

Configure the **tSnowflakeInput** component and the **tLogRow** component to retrieve data from Snowflake and output the data on the console.

**Procedure**

1. Double-click the **tSnowflakeInput** component to open its Basic settings view.

2. From the Connection Component drop-down list, select the **tSalesforceConnection** component to reuse the connection created by it.

3. Click the [...] button next to the Table field and in the pop-up dialog box, select the Use custom object check box and enter the name of the table from which the data will be retrieved in the Object Name field. In this example, it is **EMPLOYEE**, the table created by the **tSnowflakeRow** component. When done, click OK to close the dialog box.

4. Click the [...] button next to Edit schema and in the pop-up schema dialog box, define the schema by adding four columns, **ID** of int type, **NAME** and **SALARY** of String type, and **ONBOARD** of Date type. This schema is the same as the schema of the **tSnowflakeOutput** component.

5. Click OK to validate these changes and accept the propagation prompted by the pop-up dialog box.

6. Double-click the **tLogRow** component to open its Component view.

7. In the Mode area, select Vertical (each row is a key/value list) for better readability of the results.

### Closing the Snowflake connection

Configure the **tSnowflakeClose** component to close the connection to Snowflake.
Procedure

1. Double-click the tSnowflakeClose component to open the Component tab.
2. From the Connection Component drop-down list, select the component that opens the connection you need to close, tSnowflakeConnection_1 in this example.

Executing the Job to write and read data in Snowflake

After setting up the Job and configuring the components used in the Job for writing and reading Snowflake data, you can then execute the Job and verify the Job execution result.

Procedure

1. Press Ctrl + S to save the Job.
2. Press F6 to run the Job.

As shown below, the data is written into the table EMPLOYEE in Snowflake, then read from this table and outputted on the console in the Run view of the Studio.

```

3411
tSnowflakeOutput

Uses the data incoming from its preceding component to insert, update, upsert or delete data in a Snowflake table.

tSnowflakeOutput uses the bulk loader provided by Snowflake for high performance database operations.

**tSnowflakeOutput Standard properties**

These properties are used to configure tSnowflakeOutput running in the Standard Job framework.

The Standard tSnowflakeOutput component belongs to the Cloud family.

The component in this framework is available in all Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

**Basic settings**

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td>• Built-In: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
<td></td>
</tr>
<tr>
<td>• Repository: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
<td></td>
</tr>
</tbody>
</table>

This property is not available when other connection component is selected from the Connection Component drop-down list.

<table>
<thead>
<tr>
<th>Connection Component</th>
<th>Select the component that opens the database connection to be reused by this component.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Account</td>
<td>In the Account field, enter, in double quotation marks, the account name that has been assigned to you by Snowflake.</td>
</tr>
<tr>
<td>Snowflake Region</td>
<td>Select an AWS region or an Azure region from the Snowflake Region drop-down list.</td>
</tr>
<tr>
<td>User Id and Password</td>
<td>Enter, in double quotation marks, your authentication information to log in Snowflake.</td>
</tr>
<tr>
<td>• In the User ID field, enter, in double quotation marks, your login name that has been defined in Snowflake using the LOGIN_NAME parameter of Snowflake.</td>
<td></td>
</tr>
</tbody>
</table>
For details, ask the administrator of your Snowflake system.

- To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings.

| **Warehouse** | Enter, in double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake. |
| **Schema** | Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake. |
| **Database** | Enter, in double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake. |
| **Table** | Click the [...] button and in the displayed wizard, select the Snowflake table to be used. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
- **Built-In**: You create and store the schema locally for this component only.  
- **Repository**: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
  If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select **String** for the corresponding data in the **Type** column of the schema editor wizard.  
  Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
  - **View schema**: choose this option to view the schema only.  
  - **Change to built-in property**: choose this option to change the schema to **Built-in** for local changes.  
  - **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select **No** upon completion and choose this schema metadata again in the **Repository Content** window.  
  Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected. This component is end component of a data flow in your Job. It receives data from other components via a  
| **Output Action** | Select the operation to insert, delete, update or merge data in Snowflake tables.  
  The **Upsert** operation allows you to merge data in a Snowflake table based on the data that is passed to |
**tSnowflakeOutput.** After selecting **Upsert**, select the column to be used as the join key of this operation.

### Advanced settings

<table>
<thead>
<tr>
<th><strong>Additional JDBC Parameters</strong></th>
<th>Specify additional JDBC parameters for the database connection created.</th>
</tr>
</thead>
</table>
| **Use Custom Snowflake Region** | Select this check box to specify a custom Snowflake region. This option is available only when you select **Use This Component** from the **Connection Component** drop-down list in the **Basic settings** view.  
  - **Region ID**: enter a region ID in double quotation marks, for example `eu-west-1` or `east-us-2.azure`. |
| **Login Timeout** | Specify the timeout period (in minutes) of Snowflake login attempts. An error will be generated if no response is received in this period. |
| **Tracing** | Select the log level for the Snowflake JDBC driver. If enabled, a standard Java log is generated. |
| **Role** | Enter, in double quotation marks, the default access control role to use to initiate the Snowflake session.  
  This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For information about Snowflake access control model, see **Understanding the Access Control Model**. |
| **Allow Snowflake to convert columns and tables to uppercase** | Select this check box to convert lowercase in the defined table name and schema column names to uppercase. Note that unquoted identifiers should match the Snowflake Identifier Syntax.  
  If you deselect the check box, all identifiers are automatically quoted.  
  This property is not available when you select the **Manual Query** check box.  
  For more information on the Snowflake Identifier Syntax, see **Identifier Syntax**. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |

### Global Variables

<table>
<thead>
<tr>
<th><strong>NB_LINE</strong></th>
<th>The number of rows processed. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_SUCCESS</strong></td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>

### Usage

<table>
<thead>
<tr>
<th>Usage rule</th>
<th>This component is end component of a data flow in your Job. It receives data from Row &gt; Main link. It can also send error messages to other components via a Row &gt; Rejets link. The provided information about an error could be:</th>
</tr>
</thead>
</table>
|            | • The name of the column in error.  
|            | • The number of the row in error.  
|            | • The category of the error, such as a parsing error or a conversion error.  
|            | • The character offset in the line in error.  
|            | • The related error message.  
|            | • The offset of the byte in error.  
|            | • The number of the line in error.  
|            | • SQLSTATE for the error.  
|            | • Snowflake error code. |

### Related scenario

For a related scenario, see Writing data into and reading data from a Snowflake table on page 3407.
tSnowflakeOutputBulk

Writes incoming data to files generated in a folder. The folder can be in an internal Snowflake stage, an Amazon Simple Storage Service (Amazon S3) bucket, or an Azure container.

Normally, the tSnowflakeOutputBulk and tSnowflakeBulkExec components work together in a two-step process:

1. The tSnowflakeOutputBulk component uploads incoming data to a storage.
2. The tSnowflakeBulkExec component loads the data from a storage into a Snowflake database table.

You can transform the data before it is loaded into the database table in this two-step process. These two steps are fused together in the tSnowflakeOutputBulkExec component, detailed in a separate section.

tSnowflakeOutputBulk Standard properties

These properties are used to configure tSnowflakeOutputBulk running in the Standard Job framework. The Standard tSnowflakeOutputBulk component belongs to the Cloud family.

The component in this framework is available in all subscription-based Talend products.

Note: This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

Basic settings

<table>
<thead>
<tr>
<th>Database</th>
<th>Select a type of database from the list and click Apply.</th>
</tr>
</thead>
<tbody>
<tr>
<td>Property Type</td>
<td>Select the way the connection details will be set.</td>
</tr>
<tr>
<td></td>
<td>• Built-In: The connection details will be set locally for this component. You need to specify the values for all related connection properties manually.</td>
</tr>
<tr>
<td></td>
<td>• Repository: The connection details stored centrally in Repository &gt; Metadata will be reused by this component. You need to click the [...] button next to it and in the pop-up Repository Content dialog box, select the connection details to be reused, and all related connection properties will be automatically filled in.</td>
</tr>
<tr>
<td></td>
<td>This property is not available when other connection component is selected from the Connection Component drop-down list.</td>
</tr>
<tr>
<td>Connection Component</td>
<td>Select the component that opens the database connection to be reused by this component.</td>
</tr>
<tr>
<td>Account</td>
<td>In the Account field, enter, in double quotation marks, the account name that has been assigned to you by Snowflake.</td>
</tr>
<tr>
<td></td>
<td>This field is available only when you select Use this Component from the Connection Component drop-down list.</td>
</tr>
</tbody>
</table>
and select **Internal** from the **Storage** drop-down list in the **Basic settings** view.

### Snowflake Region

Select an AWS region or an Azure region from the **Snowflake Region** drop-down list.

This field is available only when you select **Use this Component** from the **Connection Component** drop-down list and select **Internal** from the **Storage** drop-down list in the **Basic settings** view.

### User Id and Password

Enter, in double quotation marks, your authentication information to log in Snowflake.

- In the **User ID** field, enter, in double quotation marks, your login name that has been defined in Snowflake using the `LOGIN_NAME` parameter of Snowflake. For details, ask the administrator of your Snowflake system.
- To enter the password, click the `...` button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click **OK** to save the settings.

This field is available only when you select **Use this Component** from the **Connection Component** drop-down list and select **Internal** from the **Storage** drop-down list in the **Basic settings** view.

### Warehouse

Enter, in double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.

This field is available only when you select **Use this Component** from the **Connection Component** drop-down list and select **Internal** from the **Storage** drop-down list in the **Basic settings** view.

### Schema

Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.

This field is available only when you select **Use this Component** from the **Connection Component** drop-down list and select **Internal** from the **Storage** drop-down list in the **Basic settings** view.

### Database

Enter, in double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.

This field is available only when you select **Use this Component** from the **Connection Component** drop-down list and select **Internal** from the **Storage** drop-down list in the **Basic settings** view.

### Schema and Edit Schema

A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word `line` when naming the fields.

**Built-In:** You create and store the schema locally for this component only.
Repository: You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.

If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select String for the corresponding data in the Type column of the schema editor wizard.

Click Edit schema to make changes to the schema. If the current schema is of the Repository type, three options are available:

- **View schema**: choose this option to view the schema only.
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected.

<table>
<thead>
<tr>
<th>Storage</th>
<th>Select the type of storage into which data will be uploaded.</th>
</tr>
</thead>
<tbody>
<tr>
<td>• <strong>Internal</strong>: Store the data in a folder in the internal Snowflake storage. You need also to specify the folder within double quotation marks in Stage Folder.</td>
<td></td>
</tr>
<tr>
<td>• <strong>S3</strong>: Store the data in an Amazon S3 folder. You need also to provide information about your S3 user account, including Region, Access Key (within double quotation marks), Secret Key, Bucket (within double quotation marks), and Folder (within double quotation marks).</td>
<td></td>
</tr>
<tr>
<td>• <strong>Azure</strong>: Store the data in an Azure folder. You need also to provide information about your Azure user account, including Protocol, Account Name (within double quotation marks), Container (within double quotation marks), Folder (within double quotation marks), and SAS Token.</td>
<td></td>
</tr>
</tbody>
</table>

| Stage Folder | Specify the Snowflake stage folder to store the data. This field is available when you select Internal from the Storage drop-down list in the Basic settings view. |

| Region | Specify the region where the S3 bucket locates. This field is available when you select S3 from the Storage drop-down list in the Basic settings view. |

<p>| Access Key and Secret Key | Enter the authentication information required to connect to the Amazon S3 bucket to be used. To enter the password, click the [...] button next to the password field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. This field is available when you select S3 from the Storage drop-down list in the Basic settings view. |</p>
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Bucket</td>
<td>Enter the name of the bucket (in double quotation marks) to be used for storing data. This bucket must already exist. This field is available when you select S3 from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td>Folder</td>
<td>Enter the name of the folder (in double quotation marks) in which you want to store data. This folder will be created if it does not exist at runtime. This property is available only when S3 or Azure is selected from the Storage drop-down list.</td>
</tr>
<tr>
<td>Server-Side Encryption</td>
<td>Select this check box to encrypt the files to be uploaded to the S3 bucket on the server side. This check box is checked by default. This field is available when you select S3 from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td>Protocol</td>
<td>Select the protocol used to create an Azure connection. This field is available when you select Azure from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td>Account Name</td>
<td>Enter the Azure storage account name (in double quotation marks). This field is available when you select Azure from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td>Container</td>
<td>Enter the name (in double quotation marks) of the Azure container used for storing data. This field is available when you select Azure from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td>SAS Token</td>
<td>Specify the SAS token to grant limited access to objects in your storage account. To enter the SAS token, click the [...] button next to the SAS token field, and then in the pop-up dialog box enter the password between double quotes and click OK to save the settings. This field is available when you select Azure from the Storage drop-down list in the Basic settings view.</td>
</tr>
</tbody>
</table>

**Advanced settings**

<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Additional JDBC Parameters</td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, encryption=1;clientname=Talend. This field is available only when you select Use this Component from the Connection Component drop-down list and select Internal from the Storage drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td>Use Custom Snowflake Region</td>
<td>Select this check box to specify a custom Snowflake region. This option is available only when you select Use This Component from the Connection Component drop-down list in the Basic settings view.</td>
</tr>
<tr>
<td><strong>tSnowflakeOutputBulk</strong></td>
<td><strong>Region ID</strong></td>
</tr>
<tr>
<td>-------------------------</td>
<td>---------------</td>
</tr>
<tr>
<td><strong>Login Timeout</strong></td>
<td>Specify the timeout period (in minutes) of Snowflake login attempts. An error will be generated if no response is received in this period.</td>
</tr>
<tr>
<td><strong>Role</strong></td>
<td>Enter, in double quotation marks, the default access control role to use to initiate the Snowflake session. This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For information about Snowflake access control model, see Understanding the Access Control Model.</td>
</tr>
<tr>
<td><strong>Use Custom Stage Path</strong></td>
<td>Select this check box to upload the data to the files generated in a folder under the stage. You need also to enter the path to the folder in the field provided. For example, to upload data to the files generated in myfolder1/myfolder2 under the stage, you need to type &quot;@~/myfolder1/myfolder2&quot; in the field. This field is available when you select Internal from the Storage drop-down list in the Basic settings view. Once selected, the Stage Folder in Basic settings view becomes unavailable.</td>
</tr>
</tbody>
</table>
| **Put Command Options** | Set parameters for the PUT command by selecting the following options from the drop-down list. The PUT command is provided by Snowflake. It uploads data to a Snowflake stage folder.  
  • **Default**: Carry out the PUT operation using the default settings, as listed in the frame to the right.  
  • **Table**: Set the PUT operation parameters using the Options table. To set a parameter, click the plus button, select the parameter from the Option column, and set the parameter value in the Value column.  
  • **Manual**: Set the PUT operation parameters in the text frame to the right manually.  
  For information about the parameters of the PUT command, see the PUT command. This field is available when you select Internal from the Storage drop-down list in the Basic settings view. |
| **Put Command Error Retry** | Specify the maximum data loading retries when an error occurs during loading data to the internal Snowflake storage. This parameter defaults to 3. A value of -1 specifies the maximum possible retries. Only -1 or positive integers are accepted. This field is available when you select Internal from the Storage drop-down list in the Basic settings view. |
| **S3 Max Error Retry** | Specify the maximum data loading retries when an error occurs during loading data to or from the S3 folder. This parameter defaults to 3. A value of -1 specifies the maximum possible retries. Only -1 or positive integers are accepted. |
This field is available when you select **S3** from the **Storage** drop-down list in the **Basic settings** view.

### Azure Max Error Retry

Specify the maximum data loading retries when an error occurs during loading data to or from the Azure folder. This parameter defaults to 3. A value of \(-1\) specifies the maximum possible retries. Only \(-1\) or positive integers are accepted.

This field is available when you select **Azure** from the **Storage** drop-down list in the **Basic settings** view.

### Use Custom S3 Connection Configuration

Select this check box if you wish to use your custom S3 configuration.

**Option:** select the parameter from the list.

**Value:** enter the parameter value.

This field is available when you select **S3** from the **Storage** drop-down list in the **Basic settings** view.

### Non-empty Storage Folder Action

Specify the action to be performed when the storage folder specified for uploading data is not empty.

- **Add New Files:** continues to process the Job and adds new files to the folder.
- **Cancel Upload:** stops the operation.
- **Replace Existing Files:** cleans the storage folder before adding new files.

### Chunk Size (bytes)

Specify the size for the files generated, which defaults to 52428800 bytes.

With this option specified, the incoming data may be stored in multiple files. Since data is stored in files on a record base, the actual size of each file generated can be larger or smaller than the specified value, but no more than the size of the last record stored in the file.

This option can significantly affect the performance. So set it carefully. See [File Sizing Best Practices and Limitations](#) for related information.

### Use Custom Local Folder

Specify a local folder as a temporary folder for holding the files generated. With this option selected, files for storing the incoming data are first generated in the specified local folder and are then moved to the specified storage after all the incoming data is uploaded.

### Number of file requests threads

Specify the number of threads used for sending Put requests in parallel when writing the data in the files.

### tStatCatcher Statistics

Select this check box to gather the Job processing metadata at the Job level as well as at each component level.

### Global Variables

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>NB_LINE</strong></td>
<td>The number of rows processed. This is an After variable and it returns an integer.</td>

<tr>
<td><strong>NB_SUCCESS</strong></td>
<td>The number of rows successfully processed. This is an After variable and it returns an integer.</td>
</tr>
</tbody>
</table>
**tSnowflakeOutputBulk**

<table>
<thead>
<tr>
<th><strong>NB_REJECT</strong></th>
<th>The number of rows rejected. This is an After variable and it returns an integer.</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>ERROR_MESSAGE</strong></td>
<td>The error message generated by the component when an error occurs. This is an After variable and it returns a string.</td>
</tr>
</tbody>
</table>

**Usage**

**Usage rule**

This component is an end component of a data flow in your Job. It receives data from other components through the **Row > Main** link.

**Related scenarios**

For use cases in relation with **tSnowflakeOutputBulk**, see the following scenario:

- Inserting transformed data in MySQL database on page 2482.
- Loading Data Using COPY Command on page 3430
tSnowflakeOutputBulkExec

Writes incoming data to files generated in a folder and then loads the data into a Snowflake database table. The folder can be in an internal Snowflake stage, an Amazon Simple Storage Service (Amazon S3) bucket, or an Azure container.

This component incorporates the operations of the tSnowflakeOutputBulk and the tSnowflakeBulk Exec components.

**tSnowflakeOutputBulkExec Standard properties**

These properties are used to configure tSnowflakeOutputBulkExec running in the Standard Job framework.

The Standard tSnowflakeOutputBulkExec component belongs to the Cloud family.

The component in this framework is available in all subscription-based Talend products.

**Note:** This component is a specific version of a dynamic database connector. The properties related to database settings vary depending on your database type selection. For more information about dynamic database connectors, see Dynamic database components on page 595.

This field is available only when **Use this Component** is selected from the **Connection Component** drop-down list. |
| **Warehouse** | Enter, in double quotation marks, the name of the Snowflake warehouse to be used. This name is case-sensitive and is normally upper case in Snowflake.  
This field is available only when **Use this Component** is selected from the **Connection Component** drop-down list. |
| **Schema** | Enter, within double quotation marks, the name of the database schema to be used. This name is case-sensitive and is normally upper case in Snowflake.  
This field is available only when **Use this Component** is selected from the **Connection Component** drop-down list. |
| **Database** | Enter, in double quotation marks, the name of the Snowflake database to be used. This name is case-sensitive and is normally upper case in Snowflake.  
This field is available only when **Use this Component** is selected from the **Connection Component** drop-down list. |
| **Table** | Click the [...] button and in the displayed wizard, select the Snowflake table to be used.  
To load the data into a new table, select **Use custom object** in the wizard and enter the name of the new table in **Object Name** field. |
| **Schema and Edit Schema** | A schema is a row description. It defines the number of fields (columns) to be processed and passed on to the next component. When you create a Spark Job, avoid the reserved word line when naming the fields.  
**Built-In:** You create and store the schema locally for this component only.  
**Repository:** You have already created the schema and stored it in the Repository. You can reuse it in various projects and Job designs.  
If the Snowflake data type to be handled is VARIANT, OBJECT or ARRAY, while defining the schema in the component, select **String** for the corresponding data in the **Type** column of the schema editor wizard.  
Click **Edit schema** to make changes to the schema. If the current schema is of the **Repository** type, three options are available:  
- **View schema:** choose this option to view the schema only. |
- **Change to built-in property**: choose this option to change the schema to Built-in for local changes.
- **Update repository connection**: choose this option to change the schema stored in the repository and decide whether to propagate the changes to all the Jobs upon completion. If you just want to propagate the changes to the current Job, you can select No upon completion and choose this schema metadata again in the Repository Content window.

Note that if the input value of any non-nullable primitive field is null, the row of data including that field will be rejected.

### Table Action
Select the action to be carried out to the table.
- **NONE**: Leave the table as is.
- **DROP_CREATE**: Remove the table and create it again.
- **CREATE**: Create a new table.
- **CREATE_IF_NOT_EXISTS**: Create the table if it does not exist.
- **DROP_IF_EXISTS_AND_CREATE**: Remove the table if it already exists and create again.
- **CLEAR**: Remove all the data records in the table.
- **TRUNCATE**: Remove all the rows in the table. This action releases the space occupied by the table.

### Output Action
Select the operation you want to perform to the incoming data and data records in the Snowflake database table. You can insert, delete, update or merge data in the Snowflake table. This option assumes that the Snowflake table specified in Table field already exists.
- **INSERT**: Insert new records in the Snowflake table.
- **UPDATE**: Update existing records in the Snowflake table.
- **UPSERT**: Create new records and update existing records. In the Upsert Key Column field displayed, you need to specify the key column to be used as the join key for the upsert operation.
- **DELETE**: Remove records from the Snowflake table.

### Storage
Select the type of storage to upload the incoming data to and to load data into the table from.
- **Internal**: Store the incoming data in a folder in the internal Snowflake storage and then load data from the folder. You need also to specify the folder within double quotation marks in Stage Folder.
- **S3**: Store the incoming data in an Amazon S3 folder and then load data from the folder. You need also to provide information about your S3 user account, including Region, Access Key (within double quotation marks), Secret Key, Bucket (within double quotation marks), and Folder (within double quotation marks).
- **Azure**: Store the incoming data in an Azure folder and then load data from the folder. You need also to provide information about your Azure user account, including Protocol, Account Name (within double quotation marks), Container (within double quotation marks), Folder (within double quotation marks), and SAS Token.
<table>
<thead>
<tr>
<th>Property</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Stage Folder</strong></td>
<td>Specify the folder under the Snowflake stage to write incoming data to and to load data from. This field is available when you select <strong>Internal</strong> from the <strong>Storage</strong> drop-down list in the <strong>Basic settings</strong> view.</td>
</tr>
</tbody>
</table>
## Advanced settings

<table>
<thead>
<tr>
<th>Field</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Additional JDBC Parameters</strong></td>
<td>Specify additional connection properties for the database connection you are creating. The properties are separated by semicolon and each property is a key-value pair, for example, <code>encryption=1;clientname=Talend</code>. This field is available only when you select <strong>Use this Component</strong> from the <strong>Connection Component</strong> drop-down list and select <strong>Internal</strong> from the <strong>Storage</strong> drop-down list in the <strong>Basic settings</strong> view.</td>
</tr>
</tbody>
</table>
| **Use Custom Snowflake Region** | Select this check box to specify a custom Snowflake region. This option is available only when you select **Use this Component** from the **Connection Component** drop-down list in the **Basic settings** view.  
- **Region ID**: enter a region ID in double quotation marks, for example `eu-west-1` or `east-us-2.azure`. For more information on Snowflake Region ID, see [Supported Regions](#). |
| **Login Timeout** | Specify the timeout period (in minutes) of Snowflake login attempts. An error will be generated if no response is received in this period. |
| **Role** | Enter, in double quotation marks, the default access control role to use to initiate the Snowflake session. This role must already exist and has been granted to the user ID you are using to connect to Snowflake. If this field is left empty, the PUBLIC role is automatically granted. For information about Snowflake access control model, see [Understanding the Access Control Model](#). |
| **Allow Snowflake to convert columns and tables to uppercase** | Select this check box to convert lowercase in the defined table name and schema column names to uppercase. Note that unquoted identifiers should match the Snowflake Identifier Syntax. If you deselect the check box, all identifiers are automatically quoted. This property is not available when you select the **Manual Query** check box. For more information on the Snowflake Identifier Syntax, see [Identifier Syntax](#). |
| **Temporary Table Schema** | Specify a schema for the temporary table. The schema must exist. |
| **Custom DB Type** | Select this check box to specify the DB type for each column in the schema. This property is available only when you select an action with Create Table from the **Table Action** drop down list in the **Basic settings**. |
| **Delete Storage Files On Success** | Delete all the files in the storage folder once the data is loaded to the table successfully. |
| **Use Custom Stage Path** | Select this check box to upload the data to the files generated in a folder under the stage. You need also to enter the path to the folder in the field provided. For example, to upload data to the files generated in `myfolder1/myfolder2` under the stage, you need to type "@~/myfolder1/myfolder2" in the field.

This field is available when you select **Internal** from the **Storage** drop-down list in the **Basic settings** view.

Once selected, the **Stage Folder** in **Basic settings** view becomes unavailable. |
| **Use Custom S3 Connection Configuration** | Select this check box if you wish to use your custom S3 configuration.

**Option**: select the parameter from the list.

**Value**: enter the parameter value.

This field is available when you select **S3** from the **Storage** drop-down list in the **Basic settings** view. |
| **Copy Command Options** | Set parameters for the COPY INTO command by selecting the following options from the drop-down list. The COPY INTO command is provided by Snowflake. It loads data to a Snowflake database table.

- **Default**: Carry out the COPY INTO operation using the default settings, as listed in the frame to the right.
- **Table**: Set the COPY INTO operation parameters using the **Options** table. To set a parameter, click the plus button, select the parameter from the **Option** column, and set the parameter value in the **Value** column.
- **Manual**: Set the COPY INTO operation parameters in the text frame to the right manually.

For information about the parameters of the COPY INTO command, see the COPY INTO command. |
| **Put Command Options** | Set parameters for the PUT command by selecting the following options from the drop-down list. The PUT command is provided by Snowflake. It uploads data to a Snowflake stage folder.

- **Default**: Carry out the PUT operation using the default settings, as listed in the frame to the right.
- **Table**: Set the PUT operation parameters using the **Options** table. To set a parameter, click the plus button, select the parameter from the **Option** column, and set the parameter value in the **Value** column.
- **Manual**: Set the PUT operation parameters in the text frame to the right manually.

For information about the parameters of the PUT command, see the PUT command.

This field is available when you select **Internal** from the **Storage** drop-down list in the **Basic settings** view. |
<p>| <strong>Put Command Error Retry</strong> | Specify the maximum data loading retries when an error occurs during loading data to the internal Snowflake storage. This parameter defaults to 3. A value of -1... |</p>
<table>
<thead>
<tr>
<th>Parameter</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>tSnowflakeOutputBulkExec</strong></td>
<td>Specifies the maximum possible retries. Only -1 or positive integers are accepted. This field is available when you select <strong>Internal</strong> from the <strong>Storage</strong> drop-down list in the <strong>Basic settings</strong> view.</td>
</tr>
<tr>
<td><strong>S3 Max Error Retry</strong></td>
<td>Specify the maximum data loading retries when an error occurs during loading data to or from the S3 folder. This parameter defaults to 3. A value of -1 specifies the maximum possible retries. Only -1 or positive integers are accepted. This field is available when you select <strong>S3</strong> from the <strong>Storage</strong> drop-down list in the <strong>Basic settings</strong> view.</td>
</tr>
<tr>
<td><strong>Azure Max Error Retry</strong></td>
<td>Specify the maximum data loading retries when an error occurs during loading data to or from the Azure folder. This parameter defaults to 3. A value of -1 specifies the maximum possible retries. Only -1 or positive integers are accepted. This field is available when you select <strong>Azure</strong> from the <strong>Storage</strong> drop-down list in the <strong>Basic settings</strong> view.</td>
</tr>
</tbody>
</table>
| **Non-empty Storage Folder Action** | Select any of the following options:  
| • **Add New Files**: continues to process the Job even if the selected storage folder already contains files and adds new files to the folder.  
| • **Cancel Upload**: stops the operation when the storage folder used for loading data is not empty.  
| • **Replace Existing Files**: cleans the storage folder before adding new files. |
| **Chunk Size (bytes)** | Specify the size for the files generated, which defaults to 52428800 bytes. With this option specified, the incoming data may be stored in multiple files. Since data is stored in files on a record base, the actual size of each file generated can be larger or smaller than the specified value, but no more than the size of the last record stored in the file. This option can significantly affect the performance. So set it carefully. See **File Sizing Best Practices and Limitations** for related information. |
| **Number of file requests threads** | Specify the number of threads used for sending Put requests in parallel when writing the data in the files. |
| **tStatCatcher Statistics** | Select this check box to gather the Job processing metadata at the Job level as well as at each component level. |
| **Global Variables** |  |
| **NB_LINE** | The number of rows processed. This is an After variable and it returns an integer. |
| **NB_SUCCESS** | The number of rows successfully processed. This is an After variable and it returns an integer. |
| **NB_REJECT** | The number of rows rejected. This is an After variable and it returns an integer. |
### Usage

**Usage rule**

This component is an end component of a data flow in your Job. It receives data from other components through the **Row > Main** link.

It can also send error messages to other components via a **Row > Rejects** link. The provided information about an error could be:

- The name of the column in error.
- The number of the row in error.
- The category of the error, such as a parsing error or a conversion error.
- The character offset in the line in error.
- The related error message.
- The offset of the byte in error.
- The number of the line in error.
- SQLSTATE for the error.
- Snowflake error code.

### Loading Data Using COPY Command

This scenario describes a Job that loads data into a Snowflake table using the COPY command, where **Copy Command Options** is customized in ON_ERROR form in case any record is rejected.

The input data contains several records, one of which violates the length limitation.

<table>
<thead>
<tr>
<th>#Name</th>
</tr>
</thead>
<tbody>
<tr>
<td>Harry</td>
</tr>
<tr>
<td>veryveryveryLongName</td>
</tr>
<tr>
<td>Jack</td>
</tr>
</tbody>
</table>

Then, the input data is inserted into a Snowflake table and the record that violates the length limitation is rejected.
Creating a Job for loading data using the COPY command

Create a Job to open a connection to access a Snowflake database, then create a Snowflake table and several records and insert these records into the table using the COPY command, and finally get and display the records on the console.

Procedure

1. Create a new Job and add a `tSnowflakeConnection` component, a `tFixedFlowInput` component, a `tSnowflakeOutputBulkExec` component, a `tSnowflakeInput` component, a `tSnowflakeClose` component, two `tSnowflakeRow` components and two `tLogRow` components by typing their names in the design workspace or dropping them from the Palette.

2. Link the `tFixedFlowInput` component to the `tSnowflakeOutputBulkExec` component using a Row > Main connection.

3. Do the same to link the `tSnowflakeOutputBulkExec` component to the first `tLogRow` component and link the `tSnowflakeInput` component to the second `tLogRow` component.

4. Link the `tSnowflakeConnection` component to the first `tSnowflakeRow` component using a Trigger > OnSubjobOk connection.

5. Do the same to link the first `tSnowflakeRow` component to the second `tSnowflakeRow` component, the second `tSnowflakeRow` component to the `tFixedFlowInput` component, the `tFixedFlowInput` component to the `tSnowflakeInput` component, the `tSnowflakeInput` component to the `tSnowflakeClose` component.

Opening a connection to access a Snowflake database

Configure the `tSnowflakeConnection` component to open a connection to access a Snowflake database.
Procedure

1. Double-click the tSnowflakeConnection component to open its Basic settings view.

   ![tDBConnection_1(Snowflake)]

   - **Database**: Snowflake
   - **Property Type**: Built-In
   - **Account**: “talend”
   - **User Id**: “comp_test”
   - **Password**: ********
   - **Warehouse**: “COMPTEST_WH”
   - **Schema**: “PUBLIC”
   - **Database**: “COMPTEST_DB”

2. In the **Account**, **User Id**, **Password**, **Warehouse**, **Schema** and **Database** fields, specify the authentication information required to access the Snowflake database.

3. Select an AWS region available for the Snowflake database from the **Snowflake Region** drop-down list. In this example, it is **AWS US West**.

Creating a Snowflake table

Configure the tSnowflakeRow to create a table. If the table already exists, it will be dropped and then created. Next, configure the tFixedFlowInput component to generate several records, one of which violates the length limitation.

Procedure

1. Double-click the tSnowflakeRow component to open its Basic settings view.

   ![tDBRow_1(Snowflake)]

2. Specify the connection details required to access Snowflake. In this example, from the **Connection Component** drop-down list displayed, select the connection component to reuse its connection details you have already defined.
